all of our cases we have found evidence of involve-of the anterior tibial nerve, but this nerve lesion either not to have been present in other cases or ve been overlooked by previous observers. In 7 r 9 cases the extensor digitorum brevis muscle was ysed, and in the remaining 2 cases weak (M.R.C. ng 3). This muscle is not one of the anterior group, and could not have been involved by direct ression in any rise of tension in the pretibial compart-. Moreover, its loss of function could not have been o muscle ischæmia from interference with its blood-y in that compartment, because in only 1 case was no galvanic response in the extensor digitorum s and in this case electromyography showed that the le was denervated, and not silent like the ischæmic muscles. Therefore we conclude that the loss of function in the extensor digitorum brevis was due to a lesion of the anterior tibial nerve. This view received additional support in 5 of our cases which showed some sensory impairment in the distribution of this nerve. The absence of sensory loss in the other cases is not surprising, since even where the anterior tibial nerve is known to be destroyed, it is often difficult to find a corresponding area of sensory loss. Since it is unlikely that the nerve was directly contused, stretched, or divided in any of our cases, the nerve lesion is probably compressive or ischæmic, and we believe that both types of lesion have occurred in this series. In cases 1, 2, and 3 the motor (and sensory) recovery of the extensor digitorum brevis muscle was complete within three months, and at no time had this muscle lost its response to faradism, but the data are somewhat incomplete in case 3. These findings are typical of compression neuropathy. In the other cases there was no return of nerve function (even after fifty-six months in case 6). The only two types of nerve lesion in continuity which lead to permanent paralysis are those due to ischæmia and to stretching. Since stretching is improbable, we believe that the pathology of the nerve lesion in these cases was ischæmic neuropathy. Unfortunately a nerve biopsy was not done in any of our cases. In those cases in which the nerve lesion recovered, the lesion may have been a mild and reversible type of nerve ischæmia.

8	Silent	Silent	Silent	N.R.

N.R., no record.

PATHOGENESIS

The syndrome consists of a lesion of the muscles of the anterior tibial compartment of the leg and a lesion of the anterior tibial nerve. On both the clinical and the pathological findings the muscular lesion may be accepted as ischæmic. The nerve lesion is, we believe, due either to compression or to ischæmia (see above).

TABLE IV—PATHOLOGICAL FINDINGS

Case no.	Interval *	Macroscopic appearances	Microscopic appearances
1	8 weeks	Avascular, necrotic	Infarcted muscle organisation and granulation tissue at periphery
2	20 days	Avascular, necrotic	Necrotic muscle tissue, new fibrous tissue formation
4	3 months	Pale and fibrotic	No necrosis, patchy muscle-fibres in dense fibrosis
5	4 months	Yellow-green and friable	Necrosis, fibrosis, hæmorrhages
6	3 months	Pale but not hard	Infarcted muscle fresh patchy hæmorrhages
7	6 months	Deep greenish, avascular	Necrosis, replacement by fibrous tissue, old and recent hæmorrhages
8	4 months	Grey, firm, and avascular	Massive ischæmic necrosis, replacement fibrosis
9	10 weeks	Hard and avascular	Ischæmic fibrosis, peripheral fibrous tissue replacement

* Interval between onset of symptoms and biopsy.

Data refer to findings in tibialis anterior muscle. In cases 4–7 specimens obtained from extensor digitorum longus muscle gave similar findings, except in case 6, in which extensor digitorum longus muscle was normal macroscopically and showed only intramuscular hæmorrhages microscopically.

able which would enable us to correlate this incidence with the "footedness" of the patients. In both cases in group 2 the right leg was affected, but it is presumably fortuitous that this limb was selected for the transfusion in both cases.

Motor Findings

Table II shows the muscles affected in each case. It will be noted: (1) that the peronei were normal in every case; (2) that, of the muscles of the anterior tibial compartment, the extensor hallucis longus was paralysed in 6 of the 9 cases; (3) that the extensor digitorum brevis, though not a muscle of the anterior tibial compartment, was paralysed in 7 cases. We regard this as a finding of considerable significance and discuss it below. In all cases the consistence of the muscles of the anterior tibial compartment was abnormal—"woody," "indurated," "firm," and "hard" were some of the adjectives used to describe them. Clinical experience associates such a finding with ischæmic necrosis of muscle. Another significant finding present in most of the cases was that, though the extensor muscles were paralysed and the patient could not voluntarily dorsiflex his foot, there was not much foot-drop. This seemed to be due to a contracture of the extensor muscles.

Electrical Reactions and Electromyography

The responses of the muscles to faradism and galvanism are also set out in table II. *It will be noted that in most cases the muscles of the anterior tibial compartment which were paralysed did not respond to either faradism or galvanism.* The exceptions are cases 2 and 3, in which the extensor digitorum longus, though showing no voluntary response, reacted to both faradism and galvanism, and case 4, in which a paralysed *tibialis* anterior did likewise. In cases 1, 2, and 9, however, the extensor digitorum brevis was paralysed but reacted *well to both faradism and galvanism.* Electromyograms were obtained from 5 of the cases (table III). In all "silence" was recorded from one or more of the muscles. *This is a reliable indication that these muscles were,* at least in part, fibrotic or necrotic.

Sensory Findings

In cases 1–4 sensation was lost over a small area, on the dorsum of the foot, based on the cleft between the first and second toes (fig. 1) in the distribution of the anterior tibial nerv case 7 hypæsthesia in this area was recorded. A *area of anæsthesia on the outer side of the leg* was in case 6; but, since there was no analgesia, and s ing in the affected area was normal, this was prob *functional in origin. In the other 3 cases* sens was normal.

Vascular Findings

At the time when the patients came under our pulsation in the arteries of the foot was judged t normal in all cases. It should be noted, however, the shortest interval between the onset of symptom examination was a week (case 3). Oscillometry done in 4 cases (cases 4–7). In case 4 the oscilla in the affected leg were slightly decreased, in the other 3 they were increased. A reflex test was done in case 8, and there was no di between the responses of the affected and the legs. Arteriography was performed on 5 cases (1 4–7). In all cases the films showed good filling o major arteries of the leg (popliteal, peroneal, and and posterior tibial), and there was no evidenc occlusion, partial thrombosis, or any other lesion in vessels. The degree of filling of the muscle bra was not good enough to enable us to draw any concl about the state of the arterial circulation in the mu

Pathological Findings (table IV)

Biopsy specimens of muscle were obtained fro *cases—all except case 3. They were obtained at* inte ranging from twenty days to six months after the o of symptoms. Specimens were obtained from the tib anterior in these 8 cases, and from the extensor digito longus in cases 4–7. In all the 8 cases the tibialis ant was macroscopically necrotic in whole or in part. *of the 4 cases* the extensor digitorum longus was necrotic. The exception was case 6, in which the su

arrested, is at least seriously impaired. If the
continues to use the muscles during this phase,
nger would be increased still further. Barcroft
illen (1939) have shown that sustained maximal
tion of a muscle causes arrest of the circulation
muscle, and this may be an important factor in
tating the onset of muscle necrosis.

ie 2 cases where the syndrome was the sequel to a
ransfusion given into the limb we suggest that the
was either not inserted properly into a vein or
slipped after insertion, with the results that the
tracked up into the anterior tibial compartment,
ly along one of the tendons, and so increased the
within the compartment. It is also possible that
e 2 cases firm bandaging of the limb to a splint
the transfusion may have aggravated the condi-
y interfering with the venous return through
cial veins.

significant findings in our cases which we believe
t this hypothesis may be repeated: (1) the
e of old and recent intramuscular hæmorrhages
e of the biopsy specimens of muscle, and (2) the
e that in some cases the lesion of the anterior
ıerve is due to compression.

hes (1948) does not accept increased tension in
iterior tibial compartment as the chief factor,
e he believes that, if it were, all three muscles
be equally affected. In his cases the proximal
of the tibialis anterior escaped damage, but this
ot so in our cases. Of the three muscles the
or hallucis longus is the most vulnerable, then the
anterior, and the extensor digitorum longus is
ikely to escape damage. There is a good deal of
ce that the extensor hallucis longus is particularly
able—e.g., in immersion foot (another condition
swelling of the leg) it is often the only muscle
leg to show pathological changes (Blackwood
This may be because it is the most deeply placed
three muscles in the compartment, or because its
uscular vascular anastomosis is less efficient
hat of the other muscles, as suggested by Clark
It is not so easy to explain why the extensor
um longus is less vulnerable than the tibialis
r. Hughes (1948) cites Blomfield as stating that
tensor digitorum longus is supplied by branches
the anterior tibial, peroneal, and posterior tibial
s, whereas the tibialis anterior is supplied by the
r tibial artery alone. Nevertheless, a uniform
tension within the anterior tibial compartment
affect equally all branches entering it irrespective
ir origin. More probably the tibialis anterior
more severely in the cases associated with
lar exertion because it is subjected to greater
than are the extensors of the toes.

s Occlusion

he above explanation is correct, it may reasonably
ed whether the syndrome might not be the result
erference with only the venous drainage from the
or tibial compartment. Though the view that
ann's ischæmia was the result of the obstruction
venous return from the affected muscles has now
disproved, it has been shown that occlusion of
enous drainage from a muscle will produce patho-
l changes. The essential finding in such cases
increase in fibrous tissue between individual
le-fibres, and the histological picture is different
that seen as a result of arterial occlusion (Griffiths
In case 4 the histological findings were of this
(see table IV), but the picture in all the other cases
is series and in those previously published was
ical with that observed in Volkmann's ischæmia.
this we may conclude that, though some cases of
nterior tibial syndrome are the result of venous
occlusion alone, in most cases the arterial circulation is also interrupted.

Metabolic Disturbance

Theoretically it may be postulated that necrosis of an active muscle might be the result either of an excessive accumulation of normal metabolites which are not removed sufficiently rapidly or of the production of abnormal metabolites. In the present cases we have no evidence which would prove or disprove this hypothesis, but we think such a mechanism is unlikely.

Conclusion

We may sum up our views on pathogenesis as follows: Sudden and unaccustomed use of the pretibial muscles in untrained men traumatises them, so that, as the result of the rupture of a few muscle-fibres or of hæmorrhage into the muscle, the swelling of the muscles that normally accompanies exertion is exaggerated; this produces tension within the rigid anterior tibial compartment sufficient to impede the circulation to the muscles and leads to ischæmic necrosis. This is the sequence of events in most cases, but any other factor which leads to a rise in tension within the compartment will produce the same effects.

DIAGNOSIS

The diagnosis depends on a history of the onset of pain in the pretibial region during or shortly after strenuous exercise, followed by signs of inflammation over the anterior tibial muscles and by inability to dorsiflex the foot and toes. The syndrome must be differentiated from cellulitis of the leg, osteomyelitis of the tibia, tenosynovitis, Volkmann's ischæmia, acute thrombophlebitis, "pretibial fever," and lesions of the lateral popliteal nerve.

In *cellulitis* and *osteomyelitis* the systemic manifestations of acute infection will be more pronounced, and the ability to move ankle and toes will usually be preserved.

Tenosynovitis of the tendons of the tibialis anterior muscle or the long extensors of the toes often develops under conditions similar to those associated with most of the cases of the anterior tibial syndrome, but the characteristic crepitus may be felt or heard, and the loss of function will be minimal.

Volkmann's ischæmia is due to more severe trauma to the limb, and there is usually an associated fracture; moreover the ischæmia will affect not only the anterior tibial group of muscles but also the flexors of the toes and even the peronei and calf muscles.

In *thrombophlebitis* the area of inflammation will be centred on a thrombosed vein, and again there should be little interference with the movements of foot and toes.

"*Pretibial fever*" is mentioned by Pearson et al. (1948) as a differential diagnosis in their case. It is "an unusual febrile illness of approximately five days' duration characterised by minimal respiratory manifestations; frontal, postorbital, and lumbar aching: leucopenia: palpable spleen; and an erythematous rash over the pretibial regions." (Daniels and Grennan 1943.)

Little difficulty arises with traction *lesions of the lateral popliteal nerve* associated with injuries to the knee-joint. In such cases the trauma is usually severe, there are undue lateral mobility of the knee and a very obvious foot-drop, pretibial pain is seldom severe, the peronei muscles are affected as well as the anterior tibial group of muscles, and the electrical excitability of the muscles will show that the paralysis is due entirely to a nerve lesion.

TREATMENT

Since complete destruction of a group of muscles in the leg has followed undue exertion, and since most of these cases are not recognised until this effect is

Infection

Since in all cases signs of inflammation were present over the affected anterior tibial compartment, infection must be considered first as a possible cause. Systemic manifestations of infection were absent or minimal, however, and in 5 cases in which the blood was examined there was no leucocytosis. On the other hand, it is well known that an inflammatory reaction is often observed in the skin overlying ischæmic muscles—e.g., in Volkmann's ischæmia. In case 4 the inflamed area was incised in the belief that there was an abscess, but only necrotic material was obtained, and a later infection which was observed in the incision was secondary. Incision or spontaneous discharge of collections of liquefied muscle is also not uncommon in limb ischæmia following fractures or injuries to blood-vessels. The pathological findings are not those of acute infective myositis; nor do they correspond to those of dermatomyositis or any other known inflammation of muscles. The evidence all suggests that the inflammation is a secondary response to muscle necrosis and not the primary reaction.

Arterial Injury or Thrombosis

Griffiths's (1940) investigation into the cause of Volkmann's ischæmia has shown that many, if not all, cases of muscle ischæmia that follow injury to a limb are due to an arterial lesion. Most workers believe that the anterior tibial syndrome is allied to Volkmann's ischæmia and is the result of arterial injury.

Sirbu et al. (1944) attribute their cases to arterial injury, without discussing the nature of the injury.

Horn (1945) suggests that the anterior tibial syndrome is the result of a traumatic thrombosis of the anterior tibial artery. He postulates a pre-existing lesion of the artery with narrowing of the lumen, perhaps the result of frequent repeated minor traumata sustained when the leg is subjected to sudden unaccustomed strains. At the onset of symptoms sudden thrombosis occurs in the already narrowed arterial lumen.

Phalen (1948) explains his case on the basis of injury or functional occlusion of the anterior tibial artery.

Hughes (1948), who made an extensive anatomical and experimental study of the blood-supply of the anterior tibial muscles in man and the rabbit, believes that the anterior tibial syndrome is due to segmental spasm of the anterior tibial artery, and has shown that, to produce necrosis of all the anterior tibial muscles, a considerable length of the artery must be affected.

The several variants of this hypothesis have points in their favour. The most important of these is that the pathology is identical with that of Volkmann's ischæmia and of muscle ischæmia following arterial wounds. It seems to us, however, that there are also many points against the view that the syndrome is the result of arterial injury. The first is the state of the circulation in the affected limb. Unfortunately none of the cases was seen by us in the acute stage. When they were examined from two weeks to six months after the onset, however, the circulation in the affected limbs, judged by pulsation in the arteries of the foot, oscillometry, vasodilatation tests, and arteriography, was considered to be normal in all cases. In only 1 of the reported cases (Hughes' case 3) is there a definite record of an absent pulse in the anterior tibial artery. It seems improbable that in so many cases a degree of arterial spasm or thrombosis sufficient to produce ischæmic necrosis of the anterior tibial muscles would exist without some degree of permanent impairment of the circulation. Though the nutrition of the hand in late cases of Volkmann's ischæmia may be excellent and the radial pulse palpable, oscillometry and arteriography nearly always reveal some permanent interference with the circulation (Holmes et al. 1944). The degree of trauma to the affected limb is, moreover, relatively slight and than would be expected to cause arterial fit young men. Indeed, in 2 of our cases the trauma sustained by the limb was the insertion needle for blood-transfusion. Admittedly in cases arterial spasm might have arisen seco venous spasm (as can occur in thrombophlebitis been favoured by the presence of oligæmic shock d the wounds elsewhere in the body, but we believe is a simpler and more likely explanation. Final none of our cases was there any clinical or pathol evidence suggesting either local or general a disease predisposing to thrombosis.

Trauma to Muscle

In most cases there is a history of unaccust strenuous exercise of the limb either at or immedi before the onset of symptoms. This strongly favour view that muscular strain is in some way intim connected with the pathogenesis. Pain in the pre region is a not infrequent complaint among athlet the early stages of training, and in the U.S. descriptively diagnosed as "shin-splints."

> "The affected muscles become firm and swollen, an attempt at active or passive flexion and extension ankle is painful. The cause is assumed to be due to rece trauma of the unconditioned muscles; nothing is kno the pathology. Rest and warm applications may be req in severe cases, but most athletes 'walk off' their ailm (Pearson et al. 1948.)

It seems probable that the present syndrome is a advanced stage of the same condition in untrained who suddenly subject their legs to unwonted musc strain. This is the basis of the explanation given Pearson et al. (1948) for their case. Necrosis of mu as a sequel to trauma is a well-established patholog condition, and it may be accepted that in most c trauma to the muscles as a result of over-exertion p an important rôle in pathogenesis. In the cases in w the syndrome developed after blood-transfusion into limb, however, there is no evidence of such mu trauma, and to explain all the cases some additio factor must be found.

Pressure in Anterior Tibial Compartment

This possibility is considered by Hughes (1948), w concludes that it is an important aggravating fac The anterior tibial compartment of the leg has very r walls, though as Hughes points out, it is not close its lower end. In the proximal two-thirds of the comp ment, where there are the muscle bellies of the tib anterior and the long extensor muscles of the there is little room to spare, and it is problemat whether the small aperture at the ankle, through w the tendons of these muscles pass and where they firmly held down by ligaments, can form an effi safety-valve if the tension rises in the proximal por of the compartment. According to Hughes (1948) tracted activity of a muscle may lead to an incr in its bulk by as much as 20% owing to the retentio excessive fluid within the tissue spaces. This swell will be aggravated if the strain on the muscle is suffici to rupture some muscle-fibres and perhaps to cause so intramuscular hæmorrhage.

From the history of most of the cases it seems rea able to suppose that all three of these events might ha occurred. The result would inevitably be an incre in tension within the anterior tibial compartm The effect of this would be to embarrass the circulati to the muscles in the compartment, either by interfe directly with the circulation in the intramuscular vasc network, as Hughes suggests, or by impeding the ve return and thus increasing the swelling and ter until the stage is reached when the arterial circulati

THROMBOANGIITIS OBLITERANS TREATED BY HYPOGLYCÆMIA

HENRYK MAZANEK
M.D. Warsaw
DICAL ADMINISTRATOR, MINISTRY OF PENSIONS, NO. 3 POLISH HOSPITAL

R 20 years ago French workers (Ambard et al. Yacoël and Boyer 1927, Yacoël and Vaquez 1927) bed cases of thromboangiitis obliterans which ad treated with injections of 10–20 units of insulin for long periods. Rest pain and claudication pain relieved, the skin became more normal in tempera- nd colour, superficial veins reappeared, and in one he oscillometric readings improved. They supposed thromboangiitis obliterans developed as a result trophic disturbance in the vessels' walls, nutrition, they suggested, was improved by n..

METHOD

full examination was carried out, including, in tful cases, radiography of the chest and an electro- iogram. Septic foci—e.g., in the teeth—were inated. Severe cardiovascular and renal disease pronounced disturbances of liver function were n as contra-indications to insulin treatment; and mild renal or hepatic dysfunction treatment was ertaken only with the utmost caution. All patients advised to stop smoking.

atients stayed in one ward under the care of specially ructed nurses. Equipment was kept at hand for the inistration, where necessary, of glucose by the avenous or nasal route.

nsulin was given twice daily—before breakfast, and ours after the midday meal. Each course of treat- t continued for about 20 days and was followed by nterval of 10 days. The number of courses depended the patient's general condition and peripheral blood- . If, after three or four courses, further treatment needed, the patient was given a rest of about 6 weeks ore the next course.

he initial dose of insulin was 40–60 units in the ming and 60–80 units in the afternoon. Thereafter amount was adjusted, according to the blood-sugar dings and clinical observations, so as to produce ll-marked hypoglycæmia lasting 3 hours. The largest ses given in this series were 80 units in the morning d 100 units in the afternoon.

actions to Insulin

Some patients proved more sensitive to insulin than hers, and for the first few days all were closely watched that if a severe reaction arose hypoglycæmia might promptly interrupted.

The blood-sugar level was estimated on the first day of treatment, and thereafter from time to time. In patients tolerating the treatment well, the level began to fall an hour after each injection: during the second and third hours it was about 40–50 mg. per 100 ml. or less.

About half an hour after an injection of insulin most patients felt hungry and tired; later some became anxious or excitable and sometimes behaved as if they were drunk. Most of them perspired profusely; some were pale and felt chilly. In the later stages consciousness sometimes became clouded and a fine tremor of the body was noticeable. Very occasionally convulsions or double vision occurred. In about half the patients the blood-pressure rose during the first and second hours and then returned to normal. In others it fell; and the effect on the pressure varied in the same patient. The pulse-rate also varied: sometimes it was quickened and sometimes slowed. In most cases leucocytosis appeared 2 hours after the start of hypoglycæmia; but the white-cell count varied in the same patients on different days. Urine analysis performed before injection of insulin and 2 and 6 hours afterwards showed no significant changes.

After about 3 hours the hypoglycæmia was ended by giving a cup of some well-sweetened drink followed after 15 minutes by a large carbohydrate meal. In emergency, when a patient became too excited or reached the stage of clouded consciousness the hypoglycæmia was quickly interrupted by injecting glucose intravenously. Latterly, however, patients who reacted in this way were given a few mouthfuls of a sweetened drink in order to diminish their hypoglycæmia; usually this had a satisfactory effect and the hypoglycæmia could then be safely maintained for up to 3 hours. Since this modification has been introduced, intravenous injections of glucose have rarely been necessary.

After their hypoglycæmic period the patients often slept soundly for 1–2 hours.

Some patients who received repeated courses of treatment developed a diminished tolerance to insulin, their reaction becoming stronger and quicker; the dose was then reduced. Occasionally a patient's reaction to the same amount of insulin varied during a single course, either from day to day or even between the morning and afternoon of the same day.

In the intervals between courses the affected limbs were submitted to short-wave diathermy, which probably helped towards the favourable results.

ILLUSTRATIVE CASE-RECORDS

Case 1.—A labourer, aged 42, had had thromboangiitis obliterans, affecting the right lower limb, since January, 1945. In July, 1945, he underwent right lumbar ganglionectomy, and in September, 1945, his right big toe was amputated. In December, 1946, the left lower limb became affected, and in September, 1947, left lumbar ganglionectomy and amputation of the left big toe were undertaken. From January, 1948, the condition of both his lower limbs deteriorated despite various treatments. He had severe claudication and rest pain and had been advised to have his legs amputated.

The patient was admitted on June 24, 1948. During the last few months he had smoked 5 cigarettes daily, and previously about 15. His general condition was poor. Both feet and the distal parts of both legs were dark blue and very cold; the toes and lower part of both feet were swollen. Pulsation was just palpable in the popliteal arteries but was impalpable in both dorsalis pedis arteries. He could hardly walk, even round the ward, owing to claudication pain. He was unable to sleep without drugs and was mentally depressed, anxiously watching his feet.

Between June 29, 1948, and May 29, 1949, nine courses of hypoglycæmia were given. Rest pain disappeared during the first course. The lower legs and feet improved continuously, becoming warm and of normal colour by the end of the fifth irreversible, it is important that any possible prophylactic measures should be made as clear and as widely known as possible.

We have been impressed by the absence of reports of the anterior tibial syndrome in trained athletes or professional footballers, and by the history of almost complete lack of graduated physical training in those who have developed the condition after exercise. It seems unwise to allow untrained young men to undergo repeated violent leg exercise such as obtains in Association football without either reasonable training or reasonable rests between each game, or to allow them to go on long route marches without considerable graduation of training beforehand.

If, however, pretibial pain develops during exercise, it is very important that a serious view of it be taken. In particular all further exertion must be prohibited for some few days; and, if any hardness or swelling of the muscles is found on examination, complete rest in bed must be ordered, with careful repeated observation of muscle function. That this syndrome is reversible at one stage of its progress is shown by the following case seen by one of us (A. B. C.) and not included in the present series:

> A sailor, aged 19, stationed ashore, played a game of football for the first time in three years. Pain in the right leg, worse on running and kicking, came on towards the end of the match, and the leg was tender and a little swollen in front below the knee. The patient was right-footed. He reported sick and was admitted to hospital that evening with the diagnosis of "cellulitis of leg."
>
> *On examination* the tibialis anterior muscle was firm and tender, with some redness over the front of the shin, and both this muscle and the extensor hallucis longus muscle were weak (M.R.C. grading 3), full dorsiflexion of the foot being impossible, though there was no foot-drop and the toes moved well. The extensor digitorum brevis was functioning normally, no sensory loss was found, and pulsation appeared normal in the arteries of the foot. The electrical reactions were weak in the affected muscles but qualitatively normal. Muscle biopsy was refused.
>
> *Treatment and Progress.*—The patient was put strictly to bed, and the function of the affected muscles gradually improved, with the result that he was well within seven days, with full muscular power. He was discharged a week later and warned about undergoing any such effort again without graduated training beforehand.

This case was considered to be a mild anterior tibial syndrome in which early cessation of exercise and early rest in bed helped to prevent the condition becoming absolute and irreversible.

If our views of the ætiology of this syndrome are correct, and if there is any way of knowing whether the process has passed the stage of possible recovery with rest in bed, then we are justified in urging that the anterior tibial space should be surgically decompressed immediately as an emergency measure. We believe that, once the patient develops foot-drop or inability to move his toes, the stage of expected recovery with conservative measures has passed. We lay particular emphasis on this since the only report we have found of recovery of function of the tibialis anterior muscle, once foot-drop has developed, was in one of the cases described by Sirbu et al. (1944) in which the muscle was decompressed on the fourth day because bilateral pretibial ischæmia had developed after a long march:

> "Longitudinal incisions were made and fasciotomy performed over both muscle bellies. Bilaterally, the tibialis anterior was avascular, greyish-white in colour, and markedly swollen. They bulged through the crural fascia, which was tightly stretched over them prior to incision. Following release of tension the muscle on the right leg recovered, aside from a small superficial area of gangrene. But on the left side, gangrene of the muscle was practically complete, requiring excision."

Since we do not believe that arterial spasm important factor in the muscle necrosis, we d advocate measures designed to relieve spasm promote vasodilatation.

After the acute stage the treatment is largely pædic. It is useless to persevere with physiotl if the muscles feel hard, do not respond to stim of any kind, are silent on electromyography, proved on biopsy to be ischæmic. An efficient ap may be required to correct a slight degree of foo

To sum up, we advise prophylaxis by suitable gra training; and, when the condition is recognised ea recommend rest in bed with the limb elevated a foot splinted in the neutral position (at right angles leg). Once paralysis has developed, surgical i pression of the muscles should be undertaken emergency.

SUMMARY

A syndrome occurring in fit young men and con of ischæmic necrosis of the muscles of the anterio compartment of the leg, with a lesion of the a tibial nerve, is described.

In most of the published cases the onset of th drome can be directly related to physical ex involving strenuous use of the leg muscles. In 2 in the present series, however, the syndrome dev after a blood-transfusion into the affected limb.

The salient clinical features are pain in the of the leg, followed by signs of inflammation ov pretibial muscles and by inability to dorsiflex th and toes. Important negative findings are normal of the peroneal muscles and a minimal degree of foo due to contracture of the ischæmic muscles.

The pathogenesis of the syndrome is discus detail, and it is considered that the sequence of e is: unaccustomed exertion → muscle trauma → inc pressure within the anterior tibial compartme impaired blood-supply to the affected muscles → isch necrosis.

The anterior tibial nerve is involved either by pression, in which case it recovers rapidly, or by isch in which case the loss of function is permanent.

It is believed that the condition can be prevente graduated physical training. If the syndrome is recog early, rest alone may prevent irreversible damag the muscles; but, if paralysis has developed, su decompression of the anterior tibial compartment a emergency procedure is advocated.

Cases 1 and 2 were seen at the Military Hospital for Injuries, Wheatley, Oxford, and case 3 at Ashford Ho Middlesex (A. B. C.). Cases 4–7 were seen at the perip nerve-injury unit at the Wingfield-Morris Orthopædic pital, Oxford (R. B. Z.), and cases 8 and 9 at the neuro unit at Gogarburn Hospital, Edinburgh (R. L. R.). W indebted to Lieut.-General Sir Neil Cantlie, K.B.E., Dir General, Army Medical Services, for permission to r cases 1 and 2. Our thanks are also due to Dr. W. R Russell and Mr. H. J. Seddon for much helpful advice d the preparation of this paper, and to Dr. G. B. S. Ro (cases 1 and 2), Dr. R. E. M. Bowden and Dr. E. Gu (cases 4–7), and Dr. W. Blackwood (cases 8 and 9) for pathological reports.

patient an ulcer on the index finger healed during cond course. In another a deep ulcer on an amputa- tump healed after four courses of treatment. In her case, with partial gangrene of the toes, healing lower; as treatment proceeded, the dead parts toes separated spontaneously and the ulcer then l.

ne intelligent patients reported that during hypo- mia they had a feeling of stronger blood-flow and th in their limbs. This started $1^1/_2$ hours after ion of insulin and continued for about 2 hours hypoglycæmia had been ended.

condition of these patients has not deteriorated treatment was discontinued. Their general health nproved and their appetite has increased. After nent they looked healthier and slept better than ; and their spirits rose—an important factor.

er treatment some cases still showed oscillometric ngs of zero at ankle-level, though the feet had ne warm and almost normal in colour and the ng distance had increased.

ore patients leave hospital they are told the nature eir disease and are warned of the importance of for their extremities. They are advised to seek tary work exposing them as little as possible to the of trauma and to cold. The less intelligent patients e written directions regarding the care of their All are urged to give up smoking.

CONCLUSIONS

e findings in this series suggest that it is worth g treatment by hypoglycæmia even in very advanced of thromboangiitis obliterans in which other methods atment have failed.

re protracted observation of a greater number of is needed; and the study reported here is being nued and extended.

seems that in this series treatment by hypoglycæmia account largely for the rapid healing of ulcers, ise in temperature and improved colour of the skin, the relief from claudication pain and other trophic ns. Admittedly, rest in bed and diathermy were tional factors contributing to the improvement of ollateral circulation in these patients, but some of had previously been treated by these and other ods without success.

may prove possible to maintain the improvement iving from time to time a further course of insulin nall doses.

SUMMARY

hromboangiitis obliterans has been treated by oglycæmia induced by insulin.

sulin was injected twice daily, in initial doses of 0 units in the morning and 60–80 units in the after- 1. Hypoglycæmia was terminated after 3 hours. routine was continued for 20 days, with a rest of t 10 days before the next course.

twenty consecutive cases improvement, usually nning during or after the first course, was evident, icularly *in the pronounced relief of trophic* urbances and rapid healing of ulcers.

ly thanks are due to the Director-General of Medical nces, Ministry of Pensions, for permission to publish this cle; and to my colleague, Dr. L. Szeszyncki, for his aboration in treatment.

DEPARTURE OF SUBSTANCES FROM THE SPINAL THECA

F. HOWARTH

ASSISTANT LECTURER IN ANATOMY, UNIVERSITY OF MANCHESTER

EUGENIA R. A. COOPER
M.D., D.Sc. Manc.
READER IN HISTOLOGY IN THE UNIVERSITY

SINCE the introduction of spinal anæsthesia by Corning in 1885, the confines of the spinal theca have been invaded by an ever-increasing army of chemical substances. Quite apart from the many varieties of spinal anæsthetics, the past fifty years have seen the injection into the spinal subarachnoid space of saline solutions, therapeutic sera, penicillin, streptomycin, various gases and radio-opaque substances.

It is well known that many of these substances appear in the blood-stream soon after their injection (Reiner *and Schnitzler 1894, Hill 1896, Ziegler 1896, Dandy and* Blackfan 1913), but the route from theca to systemic circulation remains uncertain. Three main routes have been considered in the past:

1. Ascent into the cranial subarachnoid space, with subsequent absorption into the venous sinuses via the arachnoid villi.

This is the explanation most widely accepted today (Best and Taylor 1945, Mettler 1948, Johnston and Whillis 1946) and is derived mainly from the work of Quincke (1872), Key and Retzius (1876), and Weed (1914-15 and 1922). On this hypothesis, certain drugs such as penicillin are injected into the lumbar theca in the hope that they may reach the cephalic parts of the neuraxis in effective concentration. On the other hand, when a spinal anæsthetic is administered by the same route, no significant cephalic spread is anticipated even when the "continuous" technique is adopted. This apparent discrepancy is overcome by postulating that a spinal anæsthetic becomes "fixed" to the neural elements within the theca (Stout 1929). There is neither convincing proof nor accepted definition of "fixation."

2. Removal via the lymphatic drainage of the spinal subarachnoid space.

The lymphatics have rarely figured as main routes for the drainage of substances introduced into the cerebrospinal fluid (C.S.F.). Both Quincke (1872) and Key and Retzius (1876) thought that lymphatic drainage was of small importance compared with drainage through the cranial arachnoid villi. This view was endorsed by Dandy and Blackfan (1913) and Weed (1914-15). Cathelin (1912) was one of the few who claimed an important place for the lymphatics in the absorption of C.S.F.

3. Direct passage into the local venous drainage of the spinal theca.

Direct local venous drainage of the subarachnoid space was suggested by Dandy and Blackfan (1913), who affirmed that C.S.F. passed directly into the blood by diffuse absorption from the entire arachnoid membrane. Howe (1929) believed that the main route of exit was directly through the vessel walls. Mott (1910) held that the C.S.F. was largely absorbed into the cerebral blood-vessels, while Dandy and Blackfan (1913) maintained that absorption by the spinal arachnoid accounted for a considerable fraction of the total. Weed (1914-15) claimed that spinal drainage was of much less significance than drainage through the cranial arachnoid villi, but Weigeldt (1921) agreed with Dandy and Blackfan (1913). More recently Johnston and Henderson (1932) and Hunter (1946) tentatively suggested that a proportion of an injected spinal anæsthetic was absorbed by the intra-course; the toes became reddish and somewhat warmer. Walking distance increased up to about 350 yards.

Examination on Aug. 20, 1949, showed no deterioration. The patient is now working as a cobbler.

Case 2.—A storekeeper, aged 31, had phlebitis in both legs in March, 1947. After a few months of treatment this subsided but claudication pain continued in the right leg. In March, 1948, the right foot became dark blue and cold, and ulcers developed on all the toes. In the next 4 months claudication and rest pain increased despite various treatments; and he was advised to have the limb amputated.

He was admitted on July 3, 1948. Formerly a rather heavy smoker, he had smoked only moderately during the last few months. His general condition was poor; he was pale and looked tired. The right foot was cold and cyanotic; with deep ulcers on all the toes. Pulsation of the dorsalis pedis artery was just palpable. He could walk only 20 yards, and rest pain was severe; he was receiving morphine every night.

Between July 6 and Oct. 31, 1948, four courses of treatment were given. From the 7th day of treatment the rest pain began to improve, and by the end of the first course it had disappeared completely and all the ulcers had healed, though the bone of the terminal phalanx of the big toe protruded. This was removed after the second course, and thereafter the wound healed in a few days. The foot and toe gradually became warm and of normal colour; and pulsation in the dorsalis pedis artery became equal to that on the unaffected side. Walking distance increased to about 1000 yards, after which claudication pain was only slight. The nails began to grow.

Examination on Jan. 24 and May 15, 1949, showed no deterioration. The patient complained only that in the winter his right foot was sensitive to cold and he had to wear warm socks. He was working as a storekeeper.

Case 3.—A butcher, aged 44, had had claudication pain in both legs since 1943. Periarterial sympathectomy on both femoral arteries brought about some improvement; but in November, 1947, he developed severe claudication and rest pain in his right foot. In February, 1948, the toes of his right foot became gangrenous. In March he underwent right lumbar ganglionectomy, and a month later the right leg was amputated below the knee. In July he began to complain of severe claudication pain in the left leg; and in November an ulcer appeared on the left big toe, and he was suffering severe rest and claudication pain.

The patient was admitted on Dec. 1, 1948. Formerly he had smoked about 20 cigarettes daily, but lately much less. His general condition was poor. The left foot was dark blue and cold; the distal part of the foot and the toes were swollen, and there was a deep and extensive ulcer on the big toe. No pulsation was palpable in the popliteal or dorsalis pedis arteries. His walking distance was about 15 yards; rest pain was severe, and the patient could not sleep without sedatives.

Between Dec. 7, 1948, and July 10, 1949, he was given six courses of treatment. From the 9th day of treatment the rest pain diminished, disappearing in a further few days. The ulcer on the big toe healed during the first course of treatment; the foot became gradually warmer and normal in colour; the toes became red and somewhat warmer, though not constantly so. Pulsation appeared in the popliteal artery. Walking distance increased to about 400 yards.

Examination on Aug. 25 showed no deterioration. Walking distance was perhaps slightly longer.

Case 4.—A general labourer, aged 36, had had his left leg amputated below the knee in 1944, following gangrene of the foot. In 1946 the right lower leg was amputated for the same reason. Early in 1947 a deep ulcer and subsequently gangrene developed in the left stump; and in May of that year amputation above the left knee was carried out. In January, 1948, the right stump became ulcerated; and in May the patient underwent right-sided ganglionectomy.

He was admitted on Sept. 1, 1948. On the right stump, below the knee, there was a deep ulcer $1^3/_4 \times 1^1/_2$ in., covered with atonic granulations. The stump was bluish and cool to the touch. Between Sept. 8, 1948, and Jan. 7, 1949, four courses of treatment were given. The ulcer gradually got smaller and finally healed. The stump became warmer and normal in colour. Examination on May 3 showed a good scar.

Case 15.—A schoolmaster, aged 40, had [illegible] tion pain in the right lower leg in 1942. In 1945 the lower leg was amputated owing to gangrene, and amputations followed; the wound showed no ter heal. In 1946 he underwent left lumbar [illegible] for claudication pain in the left leg; improvement lasted for a few months. During 1948 both hands became and the right index finger was amputated on account gangrene.

The patient was admitted on June 15, 1949. Formerly rather heavy smoker, he had stopped smoking a few mo before. He looked pale and tired. On the left side the d part of his foot and the toes were cold, swollen, and reddi blue; there was a deep ulcer on the third toe, and the n were hard and not growing; no pulsation would be felt in t dorsalis pedis artery. Walking distance was about 100 yar The patient complained of rest pain in the toes and he co not sleep without sedatives. Both hands were cold reddish-blue; pulsation in the left radial artery was palpable and in the right radial artery hardly so. On the index finger there was a deep ulcer $^1/_2$ in. across. Even slight movement produced effort pain in both forearms hands. The patient could write only a few words of severe pain, but he could continue after 2 minutes' he was unable to shave himself.

Between June 21 and Aug. 10 two courses of [illegible] given. Rest pain in the toes disappeared after 16 days' ment; and the ulcer on the third toe healed on the 12th The ulcer on the left index finger healed during the sec course. The foot became warm and of normal colour; toes became red and somewhat warmer, and the swell subsided. Walking distance increased to 250 yards. B hands became warmer and almost normal in colour. patient can now write and shave without pain. Treatment being continued.

RESULTS

Each of twenty consecutive cases of thromboangi obliterans, observed over a period of 14 months, respond favourably to repeated transient hypoglycæmia, indu by insulin, other methods having failed. In each th was well-marked improvement of collateral circulat The response was slow but usually became evid during or after the first course.

Improvement was manifested by relief of rest pa warmer and more normally coloured skin, relief fr claudication pain (complete in four cases), lengtheni of walking distance to a minimum of 350 yards, improv growth of nails and appearance of hair growth the dorsum of the toes, and improved genc condition.

Of the twenty patients, nine who had severe r pain reported great relief after only a few days' tre ment. In every case but one rest pain disappea completely before the end of the first course; and in t one case pain was relieved after two courses.

In all cases the skin-temperature of the affected lim rose slowly as treatment proceeded. At the same t the cyanotic or reddish-blue discoloration changed to more normal pink. These changes developed first in t upper parts of the limbs, spreading distally. Sup ficial veins became visibly distended. In three patie pulsation reappeared in the dorsalis pedis arteries, one patient in the popliteal artery and in one patient the posterior tibial artery.

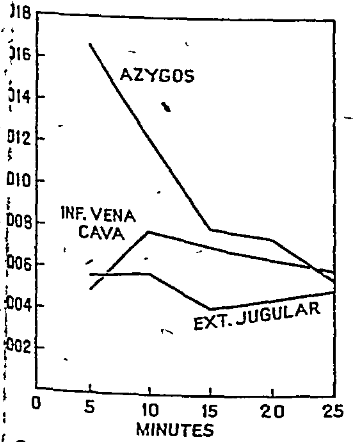
In six cases where the arms were involved the sk became warmer and the fingers and hands were restor to almost normal colour; œdema and numbness we lessened; and the patients reported that fine mo ments of the fingers, which before treatment had be clumsy, returned almost to normal and their grip beca stronger. Probably because the changes were mild upper limbs improved rather more quickly than low limbs.

In six cases ulcers of the toes healed during the fi course of treatment; healing was surprisingly quic figures are among the highest recorded for cisternal after the lumbar injection of any of the tested ances. It was evident that cephalic extension ttle to do with the reduction in local concentration. w of the small capacity of the theca in the cat, it lear that simple dilution would not account for the ntration decrement. The sampling, too, involved small volumes that this could not be considered a s source of loss.

II (*preliminary work*)

inage of the spinal subarachnoid space by the s route was investigated in twelve cats. Initially moprocaine was introduced, and to prevent possible ge of the injected solution round the needle into the ral tissues it was given by sacral cannulation. each animal samples of blood were obtained at ac intervals from the veins most likely to drain the l subarachnoid space—the vertebral, the internal external jugular, and the inferior and superior cavæ. Samples from the femoral artery and vein taken as controls. The sample of blood withdrawn any of these sources never exceeded 2 ml.

superior vena cava was cannulated at its commence- cephalic to the entrance of the vena azygos, by means of a 'Perspex' tube introduced via the right innominate vein. The inferior vena cava was cannulated via the right femoral vein, the tip of the tube reaching the level of the diaphragm. These positions were ascertained by previous measurements on dead animals and confirmed at necropsy.



—Concentration of sodium radiophosphate in veins after intrathecal injection.

The concentration proved to be similar in all these vessels except the erior vena cava, where the level was slightly er.

es II (*completed*)

he last vein to be studied was the azygos vein,* ch was cannulated just before its junction with the erior vena cava after exposure by resection of the ropriate right ribs. Respiration was maintained ficially with a pump.

reliminary experiments, in which dibromoprocaine introduced into the lumbar subarachnoid space, wed that the azygos vein carried a greater con- ration than any other vein examined. To reduce ical interference and the blood-loss attendant upon h extensive sampling, various groups of veins were npared with the azygos vein as regards the blood ncentrations within them—a procedure which appeared tifiable, since, as already mentioned, the drug levels re similar in all the other veins except the superior na cava. A commonly used combination was superior na cava, inferior vena cava, and azygos vein, so that e azygos drug level could be compared with that esent in the total cephalic and the total caudal ainage.

Dibromoprocaine appeared in the venous system most immediately, but the azygos vein carried a greater concentration than either the inferior vena cava or the superior vena cava (fig. 2), and indeed a greater concentration than any other vein examined. This immediate appearance of the substance in the circulation speaks strongly against the spread of the substance to the cranial subarachnoid villi, which must occupy an appreciable time. The question arose whether radiosodium, radiophosphorus, and radiobromine departed from the lumbar subarachnoid space in the same way as dibromoprocaine. Figs. 3*a*, 3*b*, 4, and 5 suggest that they did.

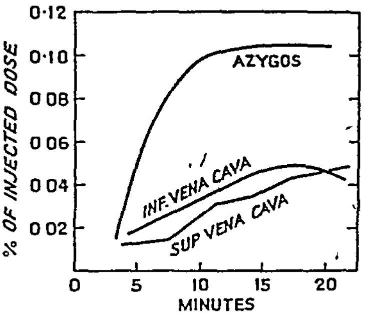


Fig. 5—Concentration of sodium radiobromide in veins after intrathecal injection.

DISCUSSION

The relative importance of the part played by the azygos vein in the total venous drainage of the spinal subarachnoid space is difficult to assess, for we have no precise information about the velocity of blood-flow in this vessel. In view of the large size of the azygos vein in the cat it seems likely that the volume of blood it carries is large. This point is being investigated, as is also the microscopic anatomy of the spinal arachnoid. Rapid removal by direct venous drainage would explain why the concentration of penicillin in the cisterna magna is so low after penicillin has been introduced in relatively huge concentration into the lumbar subarachnoid space (Walker and Johnson 1946); and it would partially explain why the medullary centres are not paralysed in patients subjected to spinal anæsthesia. The fate of intrathecal penicillin is being examined.

The distribution of various substances in those veins which can reasonably be expected to drain the spinal theca suggests that there is a direct venous drainage. The fact that a substance appears in higher concentration in the azygos system than in the venæ cavæ could theoretically be due to a depression of caval level rather than a rise in azygos level. Such a depression might be caused by removal of the substance from the arterial blood by the tissues through which it passes on its way to the venous channels. The defence against such criticism rests on the following points:

1. The tissues through which the blood returning to the superior vena cava passes are in the main different from those traversed by blood en route for the inferior vena cava. Nevertheless the blood levels in the superior and inferior venæ cavæ are very similar, except with dibromoprocaine where that of the superior vena cava is above that of the inferior vena cava.
2. Similar results have been found with dissimilar substances —sodium, phosphorus, and bromine; and it is generally accepted that no tissue specifically concentrates bromine, which is distributed throughout the extracellular body fluids.
3. None of the veins which could reasonably be expected to drain the spinal theca shows any significant differences in blood levels with the exception of the azygos.

There is a further point. The act of withdrawing blood from the azygos vein with a syringe, however carefully this is done, might possibly produce an unduly low venous pressure in the azygos system and hence promote an abnormally rapid flow of substance from theca to vein. To counter this the following experiment was performed:

The right auricle of an anæsthetised cat was cannulated via the right innominate vein, and after exposing the azygos vein an artery clip was placed upon it. An injection of radioactive dibromoprocaine was now administered by sacral cannulation and samples of auricular blood withdrawn at

---

By azygos vein is meant that vein which drains the entire azygos complex into the superior vena cava.

thecal capillaries, while Goldberg et al. (1943) also regarded direct vascular absorption as the main route of departure of such substances.

In many of the investigations on which these conclusions were based, the substances introduced into the spinal subarachnoid space were such as would never appear there otherwise. Thus Key and Retzius (1876) employed coloured gelatin; Quincke (1872) used cinnabar; Reiner and Schnitzler (1894) and Weed (1914-15) injected potassium ferrocyanide; Hill (1896) and Horbatsky (1916) chose methylene-blue; while Dandy and Blackfan (1913) used phenolsulphonephthalein. Other materials were mercury (Cotugno 1770), carmine granules (Flexner and Amoss 1914), and indian ink which has often been employed in examinations of the spinal theca. The use of such foreign substances was criticised by Levinson in 1919.

INVESTIGATION OF LOCAL VENOUS DRAINAGE

A critical proof of the direct venous drainage of the spinal subarachnoid space has never been given; indeed Weed (1922) categorically denied the possibility of diffuse absorption by vessels of the spinal subarachnoid space, since he was unable to detect histologically any traces of his "foreign substance" in the mesothelium covering the vessels. We shall here describe our own observations.

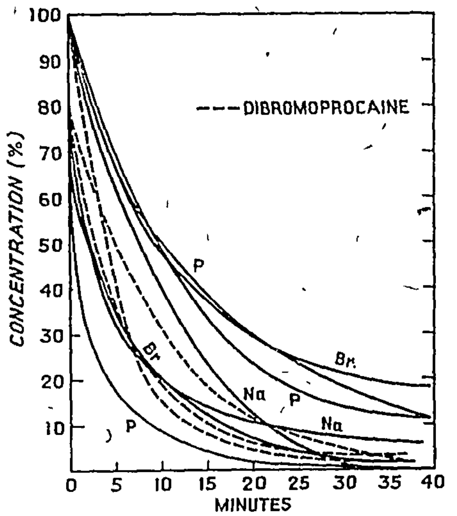

Fig. 1—Concentration curves for sodium, phosphorus, bromine, and dibromoprocaine after their injection into the spinal theca. There is an initial rapid reduction in concentration followed by a more gradual decline. (100% represents the concentration of the injected substance.)

Series I

We began by investigating the degree of cephalic spread of a substance administered intrathecally. Radioactive dibromoprocaine (Howarth 1948) was introduced into the lower reaches of the spinal subarachnoid space and its rate of departure observed. It was introduced either by lumbar puncture or by direct cannulation of the subarachnoid space where the theca lies over the sacral promontory. A hypodermic needle was inserted into the cisterna magna for sampling. Subsequently other substances were employed to ascertain whether their behaviour resembled that of dibromoprocaine. These were radiosodium as sodium chloride (0·9%), radiophosphorus, as a mixture of monobasic and dibasic sodium phosphate (1–3%), and radiobromine as sodium bromide (1%). They were given in neutral solution, the injected volume varying between 0 25 and 0·5 ml. Thirty

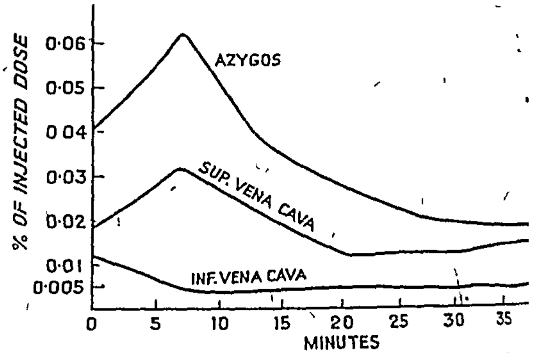

Fig. 2—Concentration of dibromoprocaine in veins after intr injection.

cats were used, and the experiments were cond under pentobarbitone anæsthesia (30 mg. per intraperitoneally.

The introduction in each instance occupied ap mately half a minute; so the pressure of injectio low, and the probability of rupture of any of th arachnoid prolongations was minimised. Where ca tion was performed, the caudal end of the theca co inspected during injection, and its flaccidity ind that the contents were not under abnormal pr After the radioactive substance had been intro samples of 0·02 ml. of C.S.F. were collected in a pipette from the needle or cannula in the lumba arachnoid space at specific intervals, the butt dried with a wisp of cotton-wool before taking sa Each sample was made up to 10 ml. with wat subjected to radio-assay. Specimens of cisternal were similarly obtained, but 0·1 ml. samples collected, because of the low concentrations found results from the lumbar theca were graphed, th centrations being expressed as a percentage concentration of the injected solution (fig. 1).

Allowing for individual variations among the an and the differing concentrations of the injected sol the curves suggest that all these substances depar the lumbar spinal theca in a similar manner. significant feature is that in no case was a concent found in the cisternal C.S.F. which could account f rapid decrement in concentration in the lumbar In the cisternal C.S.F. the maximal concentratio often so low as to render assay impracticable (less 0·0002%).

Thus in 43 minutes the concentration of s bromide in the lumbar theca had dropped to that originally injected. During this period a se samples of cisternal fluid expressed in the same showed the following concentrations:

0; 0; 0·004; 0·004; 0·01; 0·02; 0·02; 0 02.

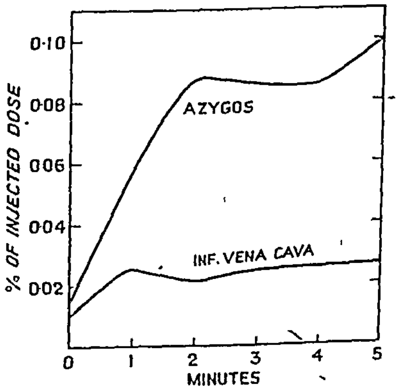

Fig. 3a.

Figs. 3a and b—Concentration of radiosodium cl in veins after intrathecal injection.

hœa, and 3 no clinical signs. Only 3 were followed until tive, the duration of known infection being nine weeks, han two weeks, and probably less than a week.

derby (3).—One child had had two earlier attacks of hœa and vomiting, but was normal when examined; thers had had no gastro-intestinal upsets. The duration fection was not followed.

chester (1).—The child had no clinical signs; the organism solated only once in five examinations, the infection being rently transient.

bovis-morbificans (8).—Seven children belonged to the mic series and had had gastro-enteritis either before or examination. The eighth child was from the clinic in the postepidemic period; he had no clinical signs remained infected for four weeks.

muenchen (2).—Both cases were neonatal and both parent; their infections lasted three and more than weeks.

bareilly (1).—The child had had three attacks of mild hœa in the two months before examination but was ng weight normally. The duration of infection was not red.

pullorum (1).—This infection was completely unapparent, the organism was found only once—at the second of examinations.

adelaide (5).—One child had had mild diarrhœa; the cases were unapparent and with negative histories. cases were followed through, the infections lasting ten, than three, two, and two weeks from the first nination.

ORIGIN OF INFECTIONS

e lack information to suggest how most of these ies became infected. They came from widely scattered s of Brisbane, with no association between infections pt possibly in some of the institutional cases. Three of records are, however, of interest:

baby received her infection with *S. muenchen* from her her at or soon after birth, and it was transmitted, presum- by the staff, to another baby in the same nursery ckerras and Mackerras 1949b).

baby, aged 3 months, was infected with *S. adelaide*. The nts were clear (3 negative specimens from each); the ehold was clean, and no positive cultures were obtained n food, utensils, dust, &c.; rats entered the house from a ny infesting uncleared ground nearby, and one of them was d to be infected with *S. adelaide*. These examinations e made late in the child's infection.

baby, aged $2^1/_2$ months, was found infected with *S. adelaide* Oct. 7. Its mother and its sister were negative. Three ks later all 3 were found to be infected. The baby may e been infected from an unknown source and have passed infection to the others.

part from these indications we can only note that except for the first neonatal *S. muenchen* infection, all infected babies were either artificially fed or received e supplemental feeding; and (2) there were sufficient nonella carriers (3%) in the adult human population in rats (1·5%) for either to have served as sources the babies' infections (Mackerras and Mackerras 9a), though no direct associations were found other n those noted.

DISCUSSION

he chief point of interest in these observations is the remely low pathogenicity of all species of salmonella Brisbane at present. There were 19,000 children under e age of 2 years in the metropolitan area at the end of 48 (Mr. S. E. Solomon, Government statistician, rsonal communication). If our clinic records approxi- ate to a random sample, there would have been upwards 600 salmonella infections scattered through this section the population during the period of the survey; t only 33 cases of salmonella gastro-enteritis were eated in hospital. Even *S. typhi-murium*, which can ndoubtedly cause severe illness, seems to have done o only in a minority of recent infections. We do not now why this is so; but we suspect that relative enignity is the normal state of the organisms, and that athogenicity is associated either with dosage of infection or, more probably, with selection by passage of virulent mutants. The conditions under which epidemics arise certainly favour the latter hypothesis.

Benignity of most endemic salmonella infections is not confined to Queensland. Rubbo (1948) doubted the capacity of the Melbourne strain of *S. derby* to kill, unless it was associated with some concurrent severe illness, and Dr. John Perry (personal communication) has also encountered many unapparent infections in a recent hospital survey in Melbourne. The phenomenon is probably general, and it is of considerable epidemiological significance, because infection may be widespread in a community but completely unsuspected and therefore not attacked. There is, in fact, a permanent potential epidemic risk, and it is easy to understand how epidemics often arise when children are crowded together under conditions which favour spread from child to child (Brehme 1948).

We feel that this infant carrier-rate of salmonella infections is just as important in the community as typhoid and dysentery carrier-rates in older persons. It certainly should receive close consideration in any plan of prevention.

SUMMARY

A salmonella carrier-rate of about 3·5% in children under the age of 2 years in Brisbane is recorded. Though the organisms seem normally to be benign, they constitute a permanent epidemic risk.

Our thanks are due to Miss Mary McCaffrey for much help in the laboratory work, and to Miss Nancy Atkinson, of the Institute of Medical and Veterinary Science, Adelaide, for identifying the strains of salmonella isolated.

EFFECT OF THE HEAD-DOWN POSITION ON THE CIRCULATION IN HYPOTENSIVE STATES

UNIVERSITY OF EDINBURGH

In the treatment of traumatic shock the clinical improvement which sometimes follows elevation of the foot of the patient's bed is generally assumed to be the result of increased blood-flow to the brain and of acceleration of the venous return from the lower part of the body. Until recently it has been customary to express these changes in terms of pulse-rate and of arterial blood-pressure, and clinical experience suggests that in most cases this is a reliable method.

However it is possible that blood-pressure records do not always truly indicate the blood-flow when the blood-pressure is low. Under high spinal anæsthesia, very low, or even unrecordable blood-pressures have been associated with apparently good oxygenation of the tissues, and recovery without obvious ill effects has followed (Griffiths and Gillies 1948).

The present study was undertaken to measure the effect of the 18° head-down position on the cardiac output and blood-pressure of animals in a hypotensive state.

Cardiac Output.—Fick in 1870 first pointed out how the cardiac output could be calculated from the gaseous exchange of

5-minute intervals. When three samples had been taken the clip was removed and three further specimens were collected. Radio-assay showed that after the removal of the clip the concentration of dibromoprocaine in the right auricle rose appreciably:

0·3–0·3–0·4—*clip off* 0·5–0·5–0·6 μg/ml.

in spite of the fact that the azygos concentration after the last sample, thirty minutes after administration, was only 0·6 μg./ml. The experiments also showed that the clamp upon the azygos vein did not deny the drug access to the circulation.

CONCLUSION

We conclude that in the cat the venous channels are a direct route of drainage from the spinal subarachnoid space. Of the veins examined, the azygos vein carries the highest concentration of substances introduced into the spinal theca.

We are grateful to Prof. A. D. Macdonald and Prof. G. A. G. Mitchell for facilities and criticism. The expenses were defrayed by the Medical Research Council to whom thanks are due.

INFANT SALMONELLA CARRIERS

I. M. MACKERRAS
M.B., B.Sc. Sydney

V. M. PASK

From the Queensland Institute of Medical Research, Brisbane

MILD or unapparent salmonella infections in infants have sometimes been recorded—e.g., by Angrist and Mollov (1946)—but they seem to have attracted little attention, and the general impression gained from published reports is that these organisms are highly pathogenic to the very young. Evidence which we have obtained recently in Brisbane, however, points to a striking contrast in the behaviour of epidemic and endemic infections.

In the epidemic series (Mackerras and Mackerras 1949a) all the children under the age of 2 years from whom *Salmonella bovis-morbificans* was isolated, had had at some stage an active, usually severe, gastro-enteritis, and the organism was found in their fæces during the incubation period, throughout the clinical illness, and up to six months after clinical recovery. About 40% retained their infections for less than a month, 25% for one to two months, and 35% for more than two months. Infections in older children and adults were mild or unapparent and generally transitory.

SURVEYS OF CHILDREN UNDER THE AGE OF 2

Group	No. of children	No. of specimens	Salmonellæ isolated
State home, 1947 ..	36	50	1 *S. bovis m* 2 *S. adelaide* 1 *S. pullorum*
State home, 1948 ..	23	23	Nil
Housing camps, &c. ..	17	23	1 *S. adelaid*
Maternal and child-welfare clinics ..	428	551	1 *S. paratyphi B* 7 *S. typhi-m* 3 *S. derby* 1 *S. chester* 1 *S. bov* 1 *S. bareilly* 2 *S. adelaide*
Total	504	647	21 strains (4%)

In addition, 6 *S. bovis-morbificans* were found in a ward of children under [illegible] ital for [illegible] tions other than [illegible], 2 *S* [illegible] *murium* in 27 chil [illegible] ver [illegible] epidemic, and 2 *S. muenchen* in week-old infants in a hospital.

Other species of salmonella were not infrequent in the same age-groups at the same time. They were scattered sporadically in the community, associated with gastro-enteritis in infants, but with little or no clinical indication of their p at any age. As a rule, these infections were relati transient, though they persisted longer in infants th in older persons. It is with the endemic infections young children that we are concerned here. Some the observations have been used incidentally in cussing the mode of spread of the epidemic (Macke and Mackerras 1949a), but they are felt to be of suffici general interest to justify a separate account here.

RESULTS OF SURVEYS

All the specimens were plated on 'Difco SS' and inoculated into tetrathionate broth, which in was plated on SS agar next day. Our findings are se in the accompanying table.

The first three groups shown in the table were stu in connexion with the epidemic, but directed our at tion to the problem; the fourth was examined specific to define it. Dr. H. C. Murphy, director of maternal child welfare, arranged for specimens of fæces to submitted to us from a continuous series of inf admitted to the clinics under his control. These child were mostly "feeding problems" but were comple unselected as regards "bowel upsets"; some had a p history of diarrhœa, some had loose motions while und observation, and most had normal stools; none w ill enough to be sent to hospital. In Dr. Murphy opinion they were a representative sample of that p of the infant population which is admitted to the clin The survey reported here lasted from March 10, 1 to May 4, 1949.

Sixteen strains of salmonella were isolated from infants in this series, 1 infant having a *S. typhi-mur* infection followed by infection with *S. adelaide* an later by another with *S. typhi-murium* four months aft the first. The over-all incidence was 3·5%. Infectio were scattered irregularly throughout the year, wi most of them in the hotter months: January, February, 1; March, 2; April, 1; May, 1; June, September, 1; October, 1; November, 1; December, They are too few to have statistical meaning in relatio to season.

The following brief analysis, by species of salmonell is based on all the infections recorded in the table an beneath it:

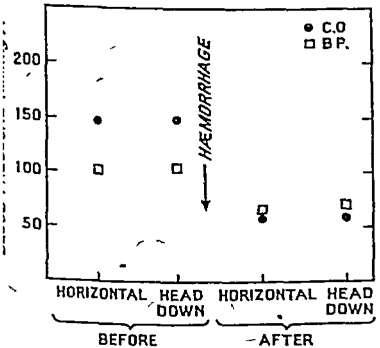
S. paratyphi-B. (1).—The child had had mild diarrhœ a fortnight previously, but had not been put to bed, and w normal when examined. It was still infected and still w when lost sight of eight weeks later.

S. typhi-murium (9).—One child had had clinical gastr enteritis five weeks previously, 5 had had intermittent m ırdiac catheter was passed into the right jugular and onwards into the right atrium. The position of ip of the catheter was determined by manometry the method of McMichael (personal communica- . A cannula was inserted into the carotid artery, arterial blood-pressure was recorded on a kymograph. noral artery was cannulated for arterial blood samples for bleeding. Heparin in doses of 1000–3000 units administered to prevent clotting in the cannulæ.

fore bleeding, two control estimations of cardiac ut were made: one in the horizontal position, and after the trunk and lower limbs of the animal had raised to an angle of 18°, this being considerably er than the tilt obtained clinically by placing 45 cm. ks under the foot of the bed. A special tilting table used for this manœuvre in which the axis of tilt cided with the position of the blood-pressure cannula ie carotid artery (fig. 1). Artificial changes in blood-sure due to variations in level of the carotid cannula thereby avoided.

he animal was bled from the femoral artery till the d-pressure fell to about 50 mm. Hg. The amount of d removed varied from animal to animal according body-weight and unknown factors. The average unt was 32% of the calculated blood volume.

wo further estimations of cardiac output were next le, in exactly the same circumstances as before norrhage. Judgment was called for in deciding the nent to take the blood samples; for example, after hæmorrhage there was a compensatory rise in blood-pressure, due no doubt to vasoconstriction. It was essential to allow this effect to reach its maximum before estimating the cardiac output. Again, after tilting, a gradual improvement in the circula- due to increasing venous return, might be antici-ed, and it was necessary to allow for this. In practice 15 minutes was allowed to elapse between any nœuvre and estimation of the cardiac output. All d samples were taken under liquid paraffin, and the gen content was estimated within six hours.



3—Effect of head-down positions on cardiac tput and blood-pressure of cat 10 before and er hæmorrhage.

t the end of the experiment the animals were llessly destroyed by bleeding.

nal Anæsthesia

he procedure in the experiments on high spinal sthesia was the same as in the hæmorrhage experi-ts, except that all the animals were in the prone ition, and instead of being bled each animal was n high spinal anæsthesia by the intrathecal injection % procaine hydrochloride in doses of 5 mg. per kg. body-weight.

rces of Error

mount of Hæmorrhage.—To reduce the blood-pressure bout 50 mm. Hg. it was necessary to remove different umes of blood from the animals; it may therefore supposed that they had different degrees of oligæmia. refore the results from one animal may not be ctly comparable with those from another. However, changes in cardiac output noted for each an are certainly valid for that experiment; and, since the investigation was not on oligæmia but on hypotension due to hæmorrhage, there is justification for comparing the results of the series.

TABLE III—EFFECT OF 18° HEAD-DOWN POSITION ON CARDIAC OUTPUT OF CATS BEFORE AND AFTER HÆMORRHAGE

Cat no.	Cardiac output (ml. per kg. of body-weight)			
	Before hæmorrhage		After hæmorrhage	
	Horizontal	Head-down	Horizontal	Head-down

8	108·7	122·0	73·2	73·3
9	121·5	120·0	39·0	41·6
10	147·5	150·0	57·2	56·8
Mean	148·46 ± 19·5	149·04 ± 19·1	52·73 ± 4·6	55·48 ± 4·5
	Mean difference = 0·58 S.E. of difference = ± 27·29		Mean difference = 2·75 S.E. of difference = ± 6·4	

Technique of Spinal Anæsthesia.—A similar source of error is present in the experiments on high spinal anæsthesia. There was no way of judging the level of anæsthesia, since the animals were under pentobarbital. It was not always possible even to be sure that the procaine solution was injected into the subarachnoid space, since cerebrospinal fluid could not always be aspirated from the needle. The fall in blood-pressure was taken as the indication of the effectiveness of the spinal anæsthesia, and it must be admitted that this is open to criticism. However, since the insertion of the needle and the injection of the procaine solution were the only obvious variables which preceded the hypotension, it seems reasonable to relate the two.

Estimation of Cardiac Output.—Estimation by the Fick principle is a well-established experimental procedure with its own experimental error, but it may be worth while to mention that leakage in the spirometer circuit can be a source of serious error. Great care must be taken to ensure that the junctions of the CO_2-absorber are completely airtight and that there is no leakage round the endotracheal catheter.

RESULTS

Low Blood-pressure due to Hæmorrhage

In dogs (tables I and II and fig. 2) the mean cardiac output per minute in the 10 animals was 188·4 ml. per kg. of body-weight in the horizontal position, and 177·3 ml. per kg. in the tilted position. After hæmorrhage

the blood. We have not found any published report on the effect of the head-down position on the cardiac output in hypotensive states. Blalock and Harrison (1927) and Burch et al. (1930) compared the effects of hæmorrhage on cardiac output under ether and under spinal anæsthesia but did not introduce postural changes. Grollman (1932), using the acetylene method, investigated changes in [illegible] sitting, and erect—in man and showed th[illegible] no effect on cardiac output owing to readjustment of the circulation. Wiggers and Werle (1942) studied the changes after hæmorrhage in laboratory animals. Cournand et al. (1943) similarly studied the circulation in cases of injury in man with various degrees of shock but did not assess the effect of posture.

	Mean difference = 11·1 S.E. of difference = ± 29·32		Mean difference = 11·2 S.E. of difference = ± 10·24	

McMichael and Sharpey-Schafer (1944) also made experiments on the changes which follow movement from the erect to the supine posture in normal men but not in persons with hypotension. Wiggers and Middleton (1944) recorded the effect on cardiac output after hæmorrhage and reinfusion and showed that there was an approximate relationship between blood-pressure and cardiac index (cardiac output per square metre of body-surface). Stead et al. (1945) found that a 70° head-up tilt in normal men led to a fall in cardiac output.

Blood-pressure.—The relationship between blood-pressure and postural changes has been demonstrated both clinically and experimentally. Priorry in 1826 (cited by Hill 1895) and Salathé (1877) were among the first to report the therapeutic value of this position in averting death in circulatory failure, and this manœuvre has since been used repeatedly. Hill (1895) and Hill and Barnard (1897), adopting changes in blood-pressure as their criteria, studied postural influences in vasomotor paralysis. Henderson and Haggard (1918), as a result of experiments in man, concluded that a 45° head-down tilt did not bring about any well-marked change in blood-pressure. However, in further work on the circulatory effects of changes in posture in normal and in shocked dogs Beale et al. (1941) found that a 70° head-down position raised the blood-pressure. Gordh (1945) concluded, from published reports and his own experimental and clinical experience of circulatory dep under anæsthesia, that this position facilitates the flow blood to the heart. He regarded it as the best resusci procedure in these circumstances, and clinical imp support this view.

Thus, though the effects of posture on blood-pres and cardiac output have been recorded on severa occasions, its effect on cardiac output in different typ of hypotensive state do not seem to have been direct studied.

METHODS

Low blood-pressure was produced in one series animals by controlled hæmorrhage and in a second seri by high spinal anæsthesia induced by the intrathecal injection of a 1% solution of procaine hydrochloride in doses of 5 mg. per kg. of body-weight.

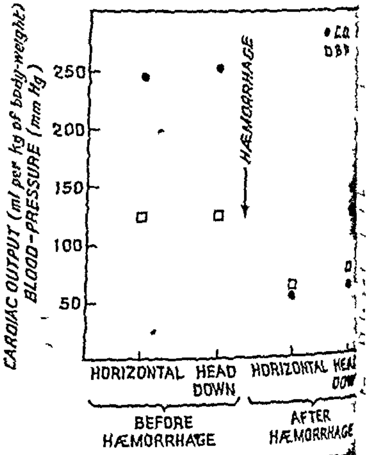

Fig. 2—Effect of head-down position on card output and blood-pressure of dog 5 before a after hæmorrhage.

It was originally intended to carry out both series of experiments in the dog, but the difficulty of thecal puncture in that animal made this impossible. According experiments on hæmorrhage were made in both the d and the cat, and those on spinal anæsthesia were m in the cat alone.

Arterial blood-pressure was recorded by cannulatio of the carotid artery, and cardiac output was estimate by the Fick principle. The arterial samples were take from the femoral artery, and the venous samples fro the right atrium by cardiac catheterisation. Blood oxygen estimations were made with the Van Slyk manometric gas-analysis apparatus. The oxygen co sumption of the animal was measured with a spiromete

Hæmorrhage

Anæsthesia was induced by the intravenous injectio of pentobarbital in doses of 32 mg. per kg. of body weight. The dogs were placed in the supine position an the cats in the prone position (fig. 1). The intratrache [illegible] wi catheter was then inserted [illegible] a stout ligature which prev

REATMENT OF A LUNG ABSCESS BY INHALATION OF MICROPULVERISED PENICILLIN

D. T. O'Driscoll
M.D., M.A.O. N.U.I.

HAT topical application should be the most efficient hod of administering penicillin in the treatment of a lised infection has long been recognised. Since the ortance of this method was emphasised by Florey Florey (1943), numerous techniques have been ribed for delivering penicillin directly to the respira- mucosa. One of the most popular was developed Barach et al. (1945), and they described its use in abscess. In these methods a solution of penicillin nebulised by the pressure from a stream of oxygen from a hand pump.

lore recently a method of using penicillin inhaled in ry form has been described by Taplin and Bryan 47), who claim good results from a mixture of micro- verised penicillin, dextrose, and diphenhydramine lrochloride in a simplified suction apparatus, and from ir clinical and bacteriological studies deduce that this thod of administration is superior to others previously d. Krasno et al. (1947) describe a method in which icillin dust, contained in a small plastic cartridge with ine-mesh wire screen at the bottom, is fitted into a all container with a detachable mouthpiece, the whole paratus not being much bigger than a whistle and very ilar in shape. Penicillin 100,000 units can be inhaled this way in a few minutes.

Krasno et al. (1948) describe 357 cases of various ections of the upper and lower respiratory tract ated in this way with very striking results, among ich there was 1 case of lung abscess treated. h apparently a clinical cure. Toxic reactions and pleasant side-effects were remarkably few. These kers emphasise that additional measures, such as ramuscular and intravenous administration of peni- lin, and local and postural drainage, should not be lected.

In the case reported here the lung abscess developed spite of these measures, which, though persisted with, d not appear to contribute to the ultimate cure. The ficulty in treating conditions such as lung abscess has en to get the antibiotic *to the organisms in the* cavity sufficient amount to sterilise it and allow the ordinary parative agents of the body an opportunity to heal the vity. The apparatus described by Krasno et al. (1947) ems to provide the answer, and their method is cheap, mple, and efficient.

CASE-RECORD

On Nov. 22, 1948, a heavy man, aged about 49, with a id complexion accentuated by a malar flush, complained a sharp pain of sudden onset in the region of the right lung , made worse by breathing, and of general malaise, for nearly 24 hours. He had served in the army and police force most of his life, and had never been ill before. He had been discharged from the army in 1946 with "heart trouble," the cardiac condition apparently having been discovered on routine examination. He himself had never complained, and had continued working in a civilian capacity without symptoms up to the previous night, when this sudden illness had come on.

On examination he was found to have a right upper lobe pneumonia, with signs of early consolidation. His temperature was 100·2°F, his pulse was rapid and irregular, the rate being about 140 per min. His heart was slightly enlarged to the left, and he had auricular fibrillation. His blood-pressure was 135/90 mm. Hg.

Treatment.—He was treated with sulphadimidine ('Sulphamezathine') and procaine penicillin G 100,000 units eight-hourly, and was rapidly digitalised. His response to treatment was excellent, and within three days his pleural pain had disappeared, his temperature had become normal, his pulse-rate had dropped to 90 per min., and his pulmonary consolidation was resolving.

Progress.—On the morning of Nov. 26 he had a sudden attack of severe dyspnœa and slight precordial pain; about 10 min. later he was in a state of severe shock, his aspect was ashen-grey, his pulse was imperceptible, and his breathing short and laboured. He was practically in extremis. Cardiac infarction was tentatively diagnosed, and the patient was given 'Omnopon' gr. $^1/_3$ and atropine gr. $^1/_{100}$. He rallied but had a second severe attack within two hours. The morphine was repeated, and naso-oral oxygen was administered through a B.L.B. mask. The patient was nursed on a water-bed in Fowler's position, and the oxygen was administered continuously for four days and then gradually stopped. The morphine was repeated as thought fit, and the patient was kept absolutely quiet. He was still afebrile. By the end of ten days he had much improved, his pulse was still irregular though the rate was now only 80 per min.; and he was fully digitalised, a maintenance dose of digoxin 0·25 mg. daily being sufficient. His heart sounds were of fair intensity, and there were no murmurs. Both his lungs were apparently clear.

On Dec. 12 his temperature suddenly rose to 102°F and pulse-rate slightly increased. A diffuse pleural rub was audible over the left lower lobe and signs of early consolidation over the right lower lobe. Sulphadimidine and procaine penicillin G were again given eight-hourly. By the 16th fluid was clearly present over the right base, and a paracentesis thoracis revealed a clear straw-coloured exudate, apparently sterile. The pleural rub was still present on the left side, but there was no evidence of lung disease on that side.

Intramuscular penicillin 100,000 units daily was continued, the sulphadimidine being stopped after eight days. The effusion was aspirated at regular intervals. The evening temperature remained about 100–101°F but fell to normal in the morning. The patient looked toxic and began to lose flesh rapidly. A dry unproductive cough was partially relieved by a sedative mixture. It was now clinically apparent that he had developed a lung abscess on the right side.

Radiography on Dec. 30 showed no definite active disease in the left lung; an effusion at the right base, apparently not very big; some streaky loss of clearness of the upper half of the chest, probably due to pleural thickening; and some residual pneumonic changes. There was no evidence of active tuberculosis or of infarction on either side. There was probably fairly considerable cardiac enlargement.

Progress.—On Jan. 14, 1949, the patient, without warning, started to cough up, first some dark evil-smelling material, and then copious quantities of yellow pus. For the next thirteen days he continued to cough up about 1–1$^1/_2$ pints of pus in 24 hours. Postural drainage was attempted, but any position other than the upright caused much distress. However, the patient found that the left prone position helped. Penicillin was continued eight-hourly, with steam inhalations of tinct. benzoin. co., expectorant cough mixtures, and a diet of as high calorie value as the patient could stomach.

Radiography on Jan. 29 revealed a collection of fluid and air in the lower and outer part of the right lung, with a large cavity, containing a small amount of fluid, close to the lateral chest wall. There was some pleural thickening, extending up to the apex, and some loss of clearness below the clavicle. There was nothing definite on the left side. The heart was enlarged.

TABLE V—EFFECT OF 18° HEAD-DOWN POSITION ON CARDIAC OUTPUT OF CATS BEFORE AND AFTER HIGH SPINAL ANÆSTHESIA

Cat no.	Cardiac output (ml. per kg. of body-weight)			
	Before anæsthesia		After anæsthesia	
	Horizontal	Head-down	Horizontal	Head-down
1	169·0	161·0	70·4	75·6
2	89 0	97·6	58·0	75·8
3	104·1	138·3	85·8	108·9
4	206·5	205·5	116·0	138·0
5	164 0	177·0	109 0	124·2
6	212·0	227·0	106·5	146·0
7	210·6	178·6	78·4	150 0
8	73·2	73·0	44 0	48·3
9	112·2	111·6	70·8	104 0
10	119 0	121·0	100·0	102·7
Mean	148·96 ± 16·87	149·06 ± 15·44	83·89 ± 7·66	107·35 ± 10·58
	Mean difference = 0·1 S.E. of difference = ± 22 87		Mean difference = 23·46 S.E. of difference = ± 13·07	

the mean cardiac output fell to 56·4 ml. per kg.—i.e., to less than half the control value. After tilting, the mean value rose slightly to 67·6 ml. per kg. The mean difference between the cardiac output in the horizontal and in the head-down position after hæmorrhage was 11·2 ml. per kg. Before hæmorrhage the same value was 11·1 ml. per kg. Neither of these values is statistically significant. The same is true of the mean blood-pressure values. A significant change in blood-pressure did not follow the use of the head-down position either before or after hæmorrhage.

In cats (tables III and IV and fig. 3) the results were similar to those obtained in dogs. The mean cardiac output before hæmorrhage was 148·46 ml. per kg. of body-weight in the horizontal position, and 149·04 ml. per kg. in the head-down position. After hæmorrhage the comparable values were 52·73 and 55·48 ml. per kg. Neither of the mean differences is statistically significant. Blood-pressure readings showed comparable variations.

Low Blood-pressure due to High Spinal Anæsthesia

In this group (tables V and VI and fig. 4) a rather different picture was seen. The mean cardiac output in the control period was 148·9 and 149·0 ml. per kg. in the horizontal and tilted positions—a difference of 0·1 ml. per kg. After high spinal anæsthesia the values were 83·9 and 107·35 ml. per kg.—a difference of 23·46 ml. per kg. This value is nearly twice the standard error of the difference and is almost statistically significant. The difference in blood-pressure values was more striking. Before spinal anæsthesia the difference between the means in the horizontal and tilted positions was 2·8 mm. Hg. After spinal anæsthesia the mean rise was 18·9 mm, which is a statistically significant increase.

TABLE VI—EFFECT OF 18° HEAD-DOWN POSITION ON BLOOD-PRESSURE OF CATS BEFORE AND AFTER HIGH SPINAL ANÆSTHESIA

Cat no.	Blood-pressure (mm. Hg)			
	Before anæsthesia		After anæsthesia	
	Horizontal	Head-down	Horizontal	Head-down
1	125	134	54	92
2	125	123	62	92
3	135	125	70	90
4	120	110	49	78
5	120	123	66	87
6	103	110	78	86
7	132	121	72	92
8	150	144	70	71
9	148	140	63	72
10	120	111	60	60
Mean	127·8 ± 4·45	125·0 ± 4·13	63·4 ± 3·08	82·3 ± 3·44
	Mean difference = 2·8 S.E. of difference = ± 6·07		Mean difference = 18·9 S.E. of difference = ± 1·6	

DISCUSSION

The results of the present study indicate that lit improvement in cardiac output and in blood-pressu results from adoption of the 18° head-down tilt in hyp tensive states following hæmorrhage. On the other han significant improvement results from the same manœuv in conditions of lowered blood-pressure in high spi anæsthesia. There are two essential differences betw the two conditions—in hæmorrhage the blood volume reduced, whereas in high spinal anæsthesia it is pres ably normal; and in hæmorrhage vasoconstrictor tone believed to be increased, whereas in high spinal anæsthe it is presumably diminished or absent. A considerati of these two points may explain why the head-do position has a different effect in the two conditions.

In hæmorrhage the chief cause of the low blo pressure and poor cardiac output is the reduced blo volume, which is not likely to be affected by gravity. high spinal anæsthesia, on the other hand, the cau the low blood-pressure is presumably widespread va dilatation, with stagnation of blood in the periph It may reasonably be expected that gravity would in the return of this stagnant blood to the right hea provided that a larger bulk of the body is elevated above the heart than is depressed below it. This was done in the present experiments. The increase in the venous return will raise both cardiac output and blood-pressure.

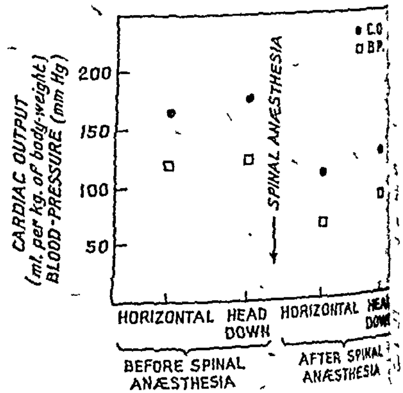

Fig. 4—Effect of head-down position on cardiac ou put and blood-pressure of cat 5 before and af spinal anæsthesia.

It is of interest that cardiac output and blood-pressur values were found to parallel each other fairly close in this study. Minor discrepancies were present whic might be due to experimental error. On the whole, whe the cardiac output fell—e.g., after hæmorrhage—th blood-pressure showed a similar fall. When cardi output rose—e.g., in the head-down position after hi spinal anæsthesia—the blood-pressure also rose. It ma be supposed that a common factor is involved, whi in all probability is the volume of venous return to th right heart.

SUMMARY

The effect of the 18° head-down position on the cardia output and blood-pressure of dogs and cats in states o arterial hypotension was studied.

Arterial hypotension was produced in one series by bleeding and in another by high spinal anæsthesia.

No significant improvement in cardiac output or blood-pressure was noted in hæmorrhagic hypotension.

In the hypotension of high spinal anæsthesia, on the other hand, a significant increase in blood-pressure followed the adoption of the 18° head-down tilt. The coincident improvement in cardiac output was on the borderline of statistical significance.

Variations in cardiac output and in blood-pressure were roughly parallel.

H. G. FARQUHAR said that toxoplasma was a on parasite of animals, being found in cats, dogs, rabbits, canaries, sparrows, and many other ls. In man infection manifested itself in four or less distinct ways: (1) a congenital infection, ich the fœtus was affected in utero; (2) an encepha- fecting older children; (3) an acute febrile illness lts, with a rash rather similar to that of typhus, ith a high case-mortality; and (4) an apparently omless infection in adults, which could often only gnosed by specific tests, but which might be con- in the female by the birth of a child affected the disease. The congenital type was manifested ns affecting the central nervous system and the and more rarely there might be anæmia, hepato- megaly, and other disturbances. The diagnosis be confirmed by finding the parasite in the blood, erebrospinal fluid, or, post mortem, in the tissues. for antibodies also helped in the diagnosis.

Reviews of Books

olytic Disease of the Newborn

M. PICKLES, D.M., Nuffield graduate assistant in nical pathology, Radcliffe Infirmary. Oxford: Black- ell Scientific Publications. 1949. Pp. 181. 15s.

e demonstration of the Rh antigenic system a e ago has led to an elegant sequence of discovery, Dr. Pickles traces in his book, beginning Landsteiner and Wiener's original work, and pro- g to the demonstration by Levine and his co- rs of the association between the Rh factor and oblastosis; thence to Fisher's brilliant analysis antigen complex, to Race and Wiener's independent nstration of the incomplete agglutinin, and finally e return of exsanguination transfusion originally sted by Hart in 1925. The logical outcome of this nce—the removal of maternal agglutinin by the f appropriate haptene during pregnancy—is still ed. In a clearly written section on Rh antigen ntibodies—a difficult subject—he notes that anti-Rh originally agglutinating, may become incomplete orage. It seems from this section that the duties e general clinical pathologist in relation to the actor end with a primary division of individuals positive and negative, and with cross-matching amond's method or with albumin solution: detailed ication of antigen and agglutinin are best left ecialists in this field. Dr. Pickles insists that liver e is a commoner cause of death than anæmia: his leads him to recommend replacement-transfusion elected, but not for all, cases of erythroblastosis. mains to be seen whether universal replacement- fusion would in fact decrease the incidence of late ous sequelæ. The reader is also cautioned against risk of overloading the circulation with excessive fusions—a danger more likely to be overlooked in ts than in adults.

Pickles has first-hand experience of his subject the laboratory and clinical angle, and since the nd covered is so wide his monograph will be of diate interest to immunologist, obstetrician, pædia- n, and not least the general practitioner, who is ften the first to meet hæmolytic disease in the orn.

hemistry in Relation to Medicine

C. W. CARTER, M.A., B.M., fellow of Queen's College, Oxford; R. H. S. THOMPSON, M.A., B.SC., D.M., professor of chemical pathology in the University of London at Guy's Hospital. London: Longmans, Green. 1949. Pp. 442. 25s.

OBLEMS which exercised the best brains last year be set as an exercise for the students tomorrow, nothing illustrates the progress of biochemical teach- in the last thirty years better than a glance through pages of this book. Its aim has been "to present e aspects of biochemistry which are significant in icine," and it has both a theoretical and an experi- tal basis. After a historical introduction and pters devoted to the chemistry of the carbohydrates, fats, and proteins, the authors pass on to discuss enzymes, biological oxidations, pigments, and electrolytes, and the acid-base balance. Nutrition follows, and the later parts of the book are devoted to a consideration of some of the body fluids, such as the urine and bile, and the function of the stomach, liver, kidney, and pancreas. Thus structural chemistry gradually gives place to bedside methods; and, though every expert will no doubt find that his own section is not as good as it might have been, few will be able to improve on the others or on the arrangements of the whole. Each chapter ends with practical work, which may be qualitative or quantitative, and the exercises are based on those which have been tried and which have not been found wanting in the medical and honours courses at Oxford.

This book is the joint effort of two experienced men, and it has both balance and judgment. It owes something to predecessors such as Cole's *Practical Physiological Chemistry*, Plimmer's *Organic and Biochemistry*, and Harrison's *Chemical Methods in Clinical Medicine*; but the authors would doubtless be the first to admit this, and they have imparted so much character to their book that it will always stand alone. There are about 600 references, mostly to journals written in English, which will be very helpful to an advanced student; but there is also a great deal of information, clearly set out and simply set out, which will be read with real pleasure by many older students who have long since taken their last examination.

Evolution of the Forebrain

The Fundamental Anatomy of the Telencephalon. G. H. W. SCHEPERS, D.SC., M.D. Johannesburg. Cape Town: Maskew Miller. 1948. Pp. 212. 50s.

IN this large monograph Dr. Schepers has collected his original anatomical studies of the telencephalon of *Testudo geometrica*, and related them to other studies of the forebrain, notably by his predecessors Herrick, Johnstone, Elliot Smith, and especially Kappers. He discusses the morphology, cyto-architecture, and vascular supply of the forebrain of different reptiles and vertebrates, and ends with a short account of their evolution in man. To those who will use this specialised work it will need no introduction.

The Sulphonamides in General Practice

E. D. HOARE, M.A., M.D. Camb., bacteriologist, Redhill County Hospital, Edgware. London: Staples Press. 1949. Pp. 90. 5s.

THE subject is presented on the conventional lines found in textbooks of pharmacology and therapeutics. The matter is well arranged and the style is easy. In a monograph of this kind it is inevitable that difficulty should arise over what to omit. Some may think it unnecessary to include all the fifty-five trade names of sulphanilamide, or to set out in detail the formulæ for ointment bases. No mention is made under Dysentery of the use of sulphonamides to supplement emetine therapy in intestinal amœbiasis.

Lehrbuch der Chirurgie

Editors: A. BRUNNER, C. HENSCHEN, H. HEUSSER, A. TUETZER, O. SCHURCH, J. VEYRASSAT. Vol. I. Basle: Schwabe. 1949. Pp. 912. Sw. fr. 74.

THIS first part of this new system of surgery describes the generalities of surgery, diagnosis, indications, tumours, skin diseases, the affections of arteries and veins, diseases of the bones, joints, and bursæ, neurosurgery, the endocrine glands, war surgery, plastic work, diets, and physical therapy. To those who read German it is a book worth buying, for the numerous authors are evidently among those who, as the preface neatly puts it, regard specialisation as the crown of general surgical practice. The slightly different outlook—the Continental outlook deriving largely from the once famous Viennese school—is interesting. The section concerned with what we call general surgery is extremely well done and is probably the best part of the book. Of the rest it can be said that, while the standard is high, the relative emphasis is often different from ours. Thus gonococcal arthritis is dismissed in four lines, while the advice to curette carbuncles and open them by parallel incision, *Progress.*—Penicillin and postural drainage were continued. By Feb. 10 the patient was deteriorating rapidly and coughing up more than 600 ml. of pus a day. The question of open drainage was now seriously considered. Despite the condition of his heart it was now obvious that the patient would not survive much longer in his present state.

Inhalation of Penicillin.—At this critical juncture the patient was given micropulverised penicillin from an 'Aerohaler' (Abbott), more or less as a last chance, and without, it must be admitted, a great deal of faith in its ultimate power. The patient inhaled 100,000 units from the aerohaler three times a day, and within three days a remarkable transformation occurred. All signs of toxæmia disappeared, the patient's appetite returned overnight and was difficult to satisfy, so voracious did it become; his eyes, which hitherto had seemed to burn in a sallow face, lost their bright ethereal light; his mental outlook altered from one of despair and despondency to exhilaration and hope; and the quantity of pus rapidly diminished till within seven days it had become but a few gobbets of mucopus in the sputum mug after 24 hours. The pleural rub disappeared in a few days. Within a fortnight the patient had regained most of his lost weight and began to talk of getting up.

Radiography on March 2 showed remarkable improvement. The cavity at the right base was much smaller, and only a trace of fluid was seen. There was fairly well-marked pleural thickening. Nothing definite was found on the left side.

Progress.—By March 20 the patient was sitting out of bed, and within a week he was walking about, completely afebrile; the cavity had almost closed; cough was absent; fibrillation was controlled with digoxin 0·25 mg. daily; and, except for a mild scoliosis due to falling in of the chest wall, the patient seemed as well as he had ever been.

The micropulverised penicillin had been given altogether for eight days; the patient receiving a total dosage of 2,400,000 units by this route. There were no ill effects.

DISCUSSION

The clinical improvement was even more spectacular than the radiograms suggested. There can be no doubt that the micropulverised penicillin was responsible for his rapid recovery. In fact, while the patient was using the aerohaler, postural drainage, which was at best poorly tolerated, was suspended. It was unfortunate that the organisms in the sputum were not identified, and perhaps it was improper to give penicillin without first ascertaining whether the organisms were sensitive, though the end-result proved conclusively that they were.

From this favourable result, and from the case reported by Krasno et al. (1948), it appears that we have at last an effective means of bringing penicillin and other antibiotics to abscess cavities cut off from blood-supply. It would be interesting to see if a similar improvement could be produced in the toxæmia resulting from secondarily infected tuberculous cavities; mixtures of various antibiotics could be used according to the organism present.

SUMMARY

A lung abscess complicating lobar pneumonia, in a patient with auricular fibrillation, was treated with micropulverised penicillin delivered through an aerohaler.

This method of treatment proved remarkably effective and saved the patient from a surgical operation.

The administration of antibiotics in the form of a fine powder, by means of a suitable inhaler, might be equally successful in other conditions with lung cavitation; in which systemic administration does not bring the antibiotic into contact with the organisms in a therapeutic concentration.

My thanks are due to Dr. W. McHugh, radiologist, Central Hospital, Galway, for his coöperation.

Medical Societies

LIVERPOOL MEDICAL INSTITUTION

NEONATAL PNEUMONIA

AT a pathological meeting on Oct. 20, with P CHARLES WELLS, the president, in the chair, Dr. A. CRUICKSHANK spoke on Studies of Neonatal Pneumo

Dr. Cruickshank illustrated some of the com conditions found in the lungs of babies who had died birth or within a few days of birth. These inclu atelectasis with well-marked interstitial emphyse polymorphonuclear cells in the alveoli of a stillb infant; inhaled squamous debris from the infant's skin; macrophages filled with phagocytosed meconiu and alveoli lined by hyaline membrane. Meconium been shown to have a harmful effect, by virtue of intensely irritant bile-salts which it contains. So workers had suggested that the unborn infant norm inhaled amniotic fluid. As regards amniotic fluid in anim the desquamated squamous cells contained in it capable of causing a foreign-body giant-cell reactio the lungs, and collapse and leucocytic emigration follo the experimental injection of cell-free, sterile amni fluid. (A similar reaction followed the injection of no saline.) Thus it must be abnormal for amniotic to reach the infant's alveoli; and this happened as a result of difficult labour or some other cause, fœtal asphyxia. If the reaction in the lungs of rabbits were an index of the reaction in man, it likely that the lungs of an infant who had inhaled m amniotic fluid would become so atelectatic that it wo not survive for more than 3 days after birth. Exp mentally a foreign-body reaction had been found 4–5 days, but such a reaction was very rare in mat from infants who died in the neonatal period. Th foreign-body reaction could arise in a baby was sh by the case of an infant who had survived for 4 d with amniotic debris in the lungs; the rarity of a finding was evidence of the uncommonness of surv for as long as 4 days.

During the discussion, Dr. J. D. HAY referred to amniotic fluid which lay in the trachea and bronchi the fœtus in utero, and the view held by some th inspiration after birth resulted in this being such into the bronchioles and alveoli.

TOXOPLASMOSIS

Dr. A. MACDONALD described various methods the laboratory diagnosis of toxoplasmosis including serum-neutralisation test on the chorio-allantois of developing chick and a complement-fixation test usi antigen prepared from infected chick-embryo tissue.[1] Liverpool three cases of congenital toxoplasmosis ha given similar results with both types of test; and 3 out of 100 "normal" sera positive compleme fixation tests were obtained—presumably as the re of symptomless infection. It was more difficult to a the significance of a positive test in patients who only one or two of the clinical signs associated with disease. Preliminary investigations had shown that incidence of positive complement-fixation tests greater in infants with anencephaly, chorioretinitis, mental retardation than in normal children. Blood fro both mother and infant should be examined, preferabl by at least two types of serological test.

In the course of the discussion, Prof. N. B. CAPO referred to Sabin's most recent paper[2] which emphasise the difficulties of serological and immunological diagnos of toxoplasmosis. Dr. J. BERKSON said that illustration of the retinal changes attributed to toxoplasmosis di not appear to him to differ from those previously labelled congenital coloboma, or old congenital choroidoretinitis One of the three cases discussed by Dr. Macdonald wa a patient of Dr. Berkson's. This is a boy, aged 9, wit convergent strabismus in a microphthalmic eye, and large area of old choroidoretinitis. He appeared to be mentally defective. The case was shown to Dr. Berkson's colleagues as one of toxoplasmosis, and radiography of the skull showed areas of cerebral calcification.

Vasodilatation

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium; the renal vasodilatation is indicated by the powerful diuresis, while its antispasmodic action appears to be largely the result of the bronchodilatation induced by the drug.

to curette tuberculous glands, and to immobilise cases of thrombophlebitis differs from the usual teaching in this country. But this is exactly why it is useful to read the book. In view of recent discussions it is interesting to find that removal of the whole saphenous vein is nearly always successful in curing varicose veins. Swiss surgeons do not seem to be acquainted with the excellent results, in the hands of Wilfred Harris, of gasserian-ganglion injections, and repair of the facial nerve in the mastoid process is not mentioned.

Die Schmerzverhütung bei chirurgischen Eingriffen

Dozent Dr. PAUL MORITSCH, Vienna: Maudrich. 1949. Pp. 279. Sch. 28.

THE publication of this well-made and well-illustrated book will be welcomed as evidence of recovery of the famous Vienna medical centre from the depredations of war and the tribulations that have followed. It may be a matter of surprise that it is a book on anæsthesia, for most Continental centres have lagged far behind those of Great Britain and America in this subject; but this also may be regarded as a good sign—an awakening to the importance of anæsthesia, the boundaries of which, the author (a surgeon) says, are now so extensive that it has a right to be considered as a separate science. He adds that in America it has been so for a long time!

Less than a third of the 260 pages deal with general anæsthesia, and some of the equipment for inhalation as illustrated is so far out of date that it would be hardly recognised by the present-day medical student here; it is perhaps significant that chloroform is given more space than any of the other inhalation anæsthetics. The main part of the book is concerned with local and regional anæsthesia in all its forms. This is illustrated by numerous accurate diagrams, and should be a useful source of information for surgeons and anæsthetists in this country whose experience of these forms of anæsthesia is limited. The text is lavishly supplied with references, most of which are from German or Austrian sources.

Mongolism (Peristatic Amentia)

M. ENGLER, M.D. Vienna, D.P.M., assistant medical officer, St. Lawrence's Hospital, Caterham. Bristol: John Wright & Sons. 1949. Pp. 208. 21s.

FEW will agree with Dr. Engler that at birth 40–50% of all mental deficiency can be classed as mongolism; nor is it necessary, in the absence of any supporting evidence, to be alarmed by his belief that the condition is on the increase. Nevertheless even on his assumption that mongolism is found in 0·01% of the population—a more modest estimate than that of Bleyer who gives 28,000 for the total affected in the U.S.A.—the condition is common enough to justify the appearance of a new book on the subject.

Much detailed work has been carried out on mongolian imbeciles since the appearance of Brousseau's book in 1928, and this is well summarised by Engler who in addition quotes extensively from his original material. It is natural to compare his book with that by Benda,[1] recently published in America. While both authors have done immense service to all workers in mental deficiency by compressing into a small compass the large and diffuse literature on mongolism, the objectivity of both is impaired by their attachment to a particular hypothesis. Benda blames the pituitary for the symptom-complex of mongolism, while Engler supports the theory of damage to the fertilised ovum from implantation in a diseased uterine mucosa. Although his book is well illustrated and produced, the terminology is loose and the text lacks scientific precision, and is at times contradictory. His choice of skin colour to illustrate the application of Mendel's law to human inheritance is unfortunate, since human skin colour does not lend itself to classification as a "recessive" or "dominant" character; and his statement that the delay in mental development in sufferers from mongolism has "hardly any connection" with the "anatomico-histological changes in the brain" is confusing for those who believe that the brain is the main organ responsible for mental development. By his own admission verbal tests are not very satisfactory for mongols, and it would valuable, in a subsequent edition of the book, to gi results of performance tests. But he has performe a notable service in making readily accessible the da needed by those attacking the baffling problem mongolism.

Techniques de détermination des groupes sang appliquées à la transfusion (Paris: Masson. Pp. 140. Fr. 500.).—Dr. Jean Moullec directs the labora of the Centre National de Transfusion Sanguine. The tec niques he describes do not differ from those used in th country; and, in fact, he gives full credit to British a American workers, especially on Rh groups. His book well produced and illustrated, but most potential read in this country have adequate publications in English, a there are no novel features about this French one.

Symptoms in Diagnosis (2nd ed. London: Baillie Tindall, and Cox. 1949. Pp. 542. 42s.).—Prof. Jonathan Meaki has not altered the purpose or arrangement of his useful boo on diagnosis, though he has slightly enlarged its scope. gives a clear and thoughtful exposition of the character a meaning of symptoms in clinical medicine, and a clear int duction to the proper study of disease. The new editi has new chapters by five of the author's colleagues at McG University, including one on symptoms in psychiatry wh all students starting work in the wards might read wi advantage—and enjoyment. The book is well suited to t student working for examinations, and has far fewer vag generalisations and hardened clichés than most.

The Story of the Johns Hopkins (Kingswood, Surre Windmill Press. 1949. Pp. 265. 12s. 6d.).—The idea of th hospital and medical school had its birth in the brain of t curious and crabbed man of genius, Johns Hopkins; an shrewd and business-like, he pursued it until it became a livi reality. By strange coincidence, the men were at hand found and foster his great scheme; for Welch, Osler, Halste and Kelly arrived on the scene to rear the infant scho of medicine, and then gradually brought it to a sta which it has never lost. The story of Johns Hopkins Hosp as related with dry humour by Dr. Bertram M. Bern is well worth reading, if only because of the intimate deta and sidelights he gives us of the early life of Osler. Osle three colleagues were, each in his own way, equally ou standing personalities, and the team-work of the four w remarkable.

Recent Advances in Physiology (7th ed. Londo J. & A. Churchill. 1949. *Pp.* 268. 21*s.*).—The physiologist i search of up-to-date information, Prof. W. H. Newton sa in his preface, is in an exceptionally favourable position ju now, thanks to the many periodicals, annual reviews, a symposiums published. It would be easy, presumably, offer a hurried and uncritical survey of this vast territory but this would hardly gain the thanks of readers of yea books. They expect some selection and evaluation of th facts, and this is what *Professor Newton* sets out to giv them, indicating to the student "certain main currents thought, anchoring him meanwhile near one of the ma sources." His chosen subjects include temperature regu tion, water diuresis, catheterisation of the heart, bloo pressure and the kidneys (written with Dr. I. Calma), colo vision, and the electrical excitation of nerve. All the chapte are new.

Notes to Lewis's Diet Charts (London: H. K. Lewi 1949. 7*s.*).—These diet charts, now revised by *Prof.* V. H. Mottram, are intended for the use of the general practitioner. There are eighteen main charts covering various conditions such as gout, tuberculosis, allergy, and kidney disease. The explanatory notes form a concise and useful summary of the use of the various diets given—though the statement that acne vulgaris "is sometimes but not invariably a symptom of scurvy" seems rather misleading. The charts themselves are easy to read and understand, and the general rules given at the bottom of each are most helpful. It must be admitted that some of the diets suggested will be difficult to follow in our present era of food restriction and rationing: for example it is stated that for allergy one should "take a diet for not more than one week consisting of meat (chicken, lamb and mutton), rice, butter, and sugar." In general, however, the charts serve their purpose, and they may well be recommended to the busy practitioner who has not the time to discuss dietary schemes with his patients.

THE LANCET

LONDON: SATURDAY, NOV. 19, 1949

Registrars

E Registrars' Association was formed with the diate aim of removing anomalies and easing hip in the new health service; and on Saturday, 26, the association, which now hopes to form up within the British Medical Association,[1] is ld an open meeting in London. One of the main will no doubt be emoluments. In general, rars are satisfied with their remuneration. but emoluments there is serious discontent. The ent goes something like this:

> The charges made by neighbouring hospitals to nt registrars differ by as much as £30 a year. is no adequate reason for this wide divergence; arge should be kept within a uniform and reasonimit as it is for housemen, who pay £100 a year.
>
> Non-resident registrars when they remain on duty ht should *not* have to pay for lodging, and possibly ot for board.
>
> The hardship for non-resident clinical registrars emain on duty outside normal times is underlined e comparative fortune of others—for example, in iagnostic departments—who have a good chance eping office hours and always sleeping at home. ings stand, the longer the non-resident registrar or is on duty, the more he is penalised financially.

rgument deserves attention. At whatever level harge is fixed, there seems no good reason why uld not be uniform. As regards the inequity harges to non-residents, some hospital authorities sidestepped by advertising all their registrar as resident; and this development the associaor the new group, will doubtless contest, particubecause at the moment an unusually high rtion of registrars are married and have to keep ne going. It is very difficult to escape the usion that registrars should normally be nonnt, and that the cost of lodging and of meals uty beyond normal hours should be defrayed e hospital. Even the London County Council, was not notably sympathetic to its married al officers, eventually conceded that those in s upwards from A.M.O.2 (in which the graduate, g been qualified at least 1 year, held a 2-year ntment) might live outside the hospital, with esponding allowance.

econd topic that may be raised at next week's ng is representation. Registrars have complained fficulty in making their voices heard; but ess has been made with their securing a place e B.M.A.'s Central Consultants and Specialists mittee, and with agreement to the principle they should be represented on the regional mittees.[1] Furthermore, the new group, backed e authority of the British Medical Association, now be strongly placed for central negotiation. e remains, however, the question of representation e medical advisory committees of local managecommittees. It may be reasoned that registrars are neither experienced enough nor permanent enough in tenure to earn places on these bodies. To this the registrars retort that they, who work in the hospital throughout the day and sometimes also the night, know more of its workings than consultants, who are often in the building for no more than a few hours during the day and not at all at night, and who may never stir from their own department. Enthusiasm and initiative, it is rightly said, can best be assured by the offer of a responsible place in the management of the hospital's medical affairs.

By far the weightiest matters, however, which will have to be considered next week are the conditions under which registrars now work and their future prospects. Unhappily there are signs of growing cleavage between the registrars in teaching and in non-teaching hospitals. In more than one region the impression is gaining ground that the chance of securing a consultant appointment is unreasonably small for candidates from the non-teaching hospitals; and in some regions this impression has already reduced the number of applications for junior posts in such hospitals. The best hope of a remedy seems to lie in adjustment of the method of appointing registrars. At present appointments are made by management committees; and this practice could possibly be allowed to continue in respect of junior registrars, who do not always proceed with specialist training. As regards the two higher grades, however, much might be gained by transferring the duty of appointment to the regional board. The first advantage would be that those who appoint the consultants would have a chance to examine the merits of those who hope eventually to apply for consultant posts; and in this way the standard sought by the boards might be more satisfactorily achieved. Secondly, the way would be cleared for a healthy interchange of duties between registrars in teaching and in non-teaching hospitals, with a corresponding variation in emphasis between the academic and the practical. The one serious disadvantage is that members of the hospital staff might have less chance to influence the choice of a registrar by their judgment of his compatibility. By whatever method they are selected, registrars and senior registrars should not greatly exceed the number that can eventually gain a consultant post. Some excess is of course reasonable. since no-one can predict with certainty that a postgraduate engaged in learning will qualify to practise his specialty; but a fair measure of competition has always been the registrar's lot, and this he is still willing to accept.

Even if, as we believe, this adjustment in the method of selection would aid those in training, it would still do nothing for the many who are waiting doggedly, if with fading hope, for a place among the consultants. Should they continue to wait, or seek an appointment in the Services or overseas, or turn to general practice? They expected to know the answer when the consultant establishments were finally determined; but unfortunately it must be some months yet before this work is completed. and even then lack of money may prevent the boards from filling all the new posts. Meanwhile, it might be helpful if hospital boards could announce, collectively or individually, the number and nature of the appointments which they expect to advertise within, say, the next eighteen

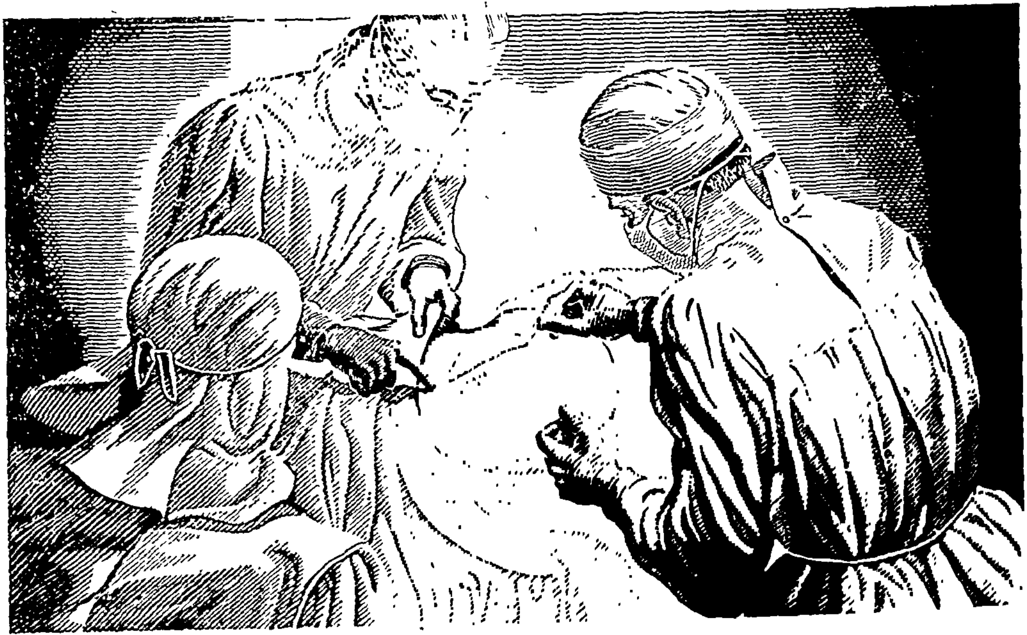
A&H

penicillin nonad tulle



In all branches of surgery, Penicillin Nonad Tulle has been welcomed as an effective bacteriostatic dressing for operation wounds, including those of eyes, ears and nose, and those of skin grafting.

This non-adherent, sterilized gauze dressing of wide mesh is impregnated with an emulsifying base containing 1,000 units of penicillin per gramme, equivalent to 160 units of penicillin per square inch of tulle.

Dressings of Penicillin Nonad Tulle are easily and painlessly removed without destroying the granulation and epithelial tissues in process of formation.

PENICILLIN NONAD TULLE

In tins, containing 10 pieces each 4" × 4", or a strip dressing 4" × 2 yds.

embership of Management Committees

HE Minister of Health's circular on filling vacancies ıospital management committees[1] throws several of light on the official theory of hospital adminis- ion. After the decision to nationalise the hospitals taken in 1945, a framework for the new service put together with great skill and an almost nch logic. It culminated in the Minister at the x, and the Minister was synonymous with the lic interest: the regional boards were the Minister's nts, and the hospital management committees e thus a local interpretation of the public interest. this simplification obscured the need to define proper function of the hospital management com- tees and to decide what kind of people should be ointed to them. Little thought was given to the stion of whom (if anyone) they should "represent," what part on them should be played by doctors.

et us look first at the medical membership. Amid upheaval created by the Act the proposition that dical men should be appointed in some numbers the hospital management committees received a eral blessing from the medical world, though ually it is quite contrary to the best practice of the mer voluntary hospital. The new circular is a n that the Minister appreciates the mistake that s then made. It points out that the annual recur- ice of vacancies affords an opportunity for reviewing present composition of committees, and continues:

> "(a) The Act requires consultation of senior medical nd dental staff—through staff committees of hospitals r groups or other convenient channels—and it is learly intended that one element in the membership f Committees shall be this professional one. The roportion of professional members should not, however, e high. It is very undesirable that in the com- osition of Committees any professional element should form a substantial proportion of the members. The Committee must essentially be and remain a group of non-professional members of the local community, rendering voluntary service in the public-spirited tradition of the past and in the interests of the community; and any implication that the Committee was a body more likely to be concerned with the interests of the staff than those of the community would be most unfortunate.
>
> "(b) Medical and dental members should normally be derived as implied by the Act, from names proposed by the hospital staffs and not from other sources."

ese wise provisions go far to re-establish the proper tus of the medical committee of the hospital. e very first principle of good hospital administration a proper understanding of the relation between the committee on one side and the medical committee the other. At the heart of the hospital lies a ntract: the lay committee agrees to entrust the re of the patients to the medical staff and to refrain om interference in medical matters, while the medical aff, for their part, agree to accept a collective sponsibility for the discharge of their duty, and to efrain from influencing the lay committee in favour this or that save through their own medical committee and its appointed representatives. If hence- orth the regional boards will normally appoint medical (and dental) representatives on the hospital management committees *only* on the recommendation of the medical and dental staff, this principle will be secured. The Ministry is to be congratulated on pushing into place a cornerstone of the edifice which was left dangerously loose three years ago; and though one effect of its recommendations may be a decrease in the number of medical members of management committees. the ultimate and more important effect will, we believe, be an increase in the influence exerted by medical opinion.

How should the lay member be chosen? The position here is much less satisfactory. The Act required consultation with various representative interests when the new bodies were first established; and the Minister's circular now says that such consultation, though not statutory when filling vacancies, is nevertheless desirable. So far there will be general agreement. But the circular may be going much further when it says:

> ". . . it is important that the community served by each Committee should be as closely as possible identified with the Committee and the hospitals it controls, and the Board should therefore consider whether there are any additional organisations representing the consumer interest which they could usefully consult. . . ."

The appearance of the phrase "consumer interest" marks a new departure, and if it passes unchallenged a time may soon come when it will be assumed that any consumer interest has a right to be consulted, and by inference to be represented. Like the Ministry, we are anxious that public opinion should play its part in the management of hospitals: by such means as the meetings described in an annotation this week people should be brought to feel that these are their own hospitals, which they can criticise, support, and help to improve—not institutions outside their control, provided by a paternal State. On the other hand, members of the lay board of a hospital ought to be chosen primarily for their personal qualities; and the representation of "consumer interest" imports into the hospital world a theory of government which has evident limitations in medicine or the social services. (Must we, for example, expect to see "aged chronics" claim an increasing share in the management?) Though the lay committee should represent the public, and should not be a collection of experts, the men and women appointed should be, in GOLDWATER's words, both "familiar with the principles and methods of business administration" and "inspired by sound ideals of social service." This is quite compatible with the wide consultation required by the Act; it may be less compatible with the pursuit of consumer representation for its own sake.

On a third important point, closely related to the last, the circular is silent. How much weight ought the regional boards to give to the views of the hospital management committee when appointing its new members? The hospital management committee is, it is true, first on the list of those who have to be consulted; but a strong case could be made for the view that this is not in itself enough. If a hospital management committee is to consolidate a sense of corporate responsibility it must possess some real power to control its own membership. There is here, of course, a dilemma: on the one hand the chain of months, together with the figures for registrars now at work. The ratio of trainee specialists to consultants should, as we have indicated,[2] not much exceed 1 to 4; and such a survey would certainly reveal that, even allowing for new appointments, this balance has become seriously disturbed. The boards' figures would necessarily be provisional, since they are still uncertain whether the money they need will be forthcoming; but this should not greatly deter them. Registrars have worked too long in the dark; their urgent need is for illumination, however imperfect; and the boards ought to provide this without further delay.

Sites of Antibody Production

For as long as the existence of antibodies has been known immunologists have sought to discover their nature, mode of formation, and site of production. The earlier experiments suggested that they were formed in the reticulo-endothelial system, and during the past twenty years various workers have shown that the lymph-glands draining injection areas play an important part in their production. There is also evidence—discussed in these columns last week (p. 899)—that lymphocytes synthesise γ-globulin, which is an important source of antibodies; though Ehrich and others[3] take the view that plasma cells rather than lymphocytes are the main antibody-producers. Up to now investigations have been almost entirely limited to such particulate antigens as bacterial suspensions, heterologous red cells, and viruses. The antibodies produced by these antigens cannot be measured with the same quantitative precision as can most antitoxins. The only earlier work using soluble antigens appears to be that of Osterlind[4] and of Burnet.[5] Burnet found that in immune rabbits given a secondary stimulus of staphylococcus toxoid there was considerable enlargement of the lymph-node on the inoculated side but there was only a barely significant difference in the antitoxic titres before and after the toxoid. Osterlind showed that the injection of diphtheria toxoid into the leg of a normal rabbit caused enlargement of the regional lymph-gland, while the germinal centres increased in size but not in number. After a similar injection into an immune rabbit the germinal centres increased in number at the time of the maximal secondary response.

The work of Oakley and his colleagues,[6] just published, has mainly been done with diphtheria and tetanus alum-precipitated toxoids; the corresponding antitoxins can be measured with an accuracy well within 10%. They show conclusively that after secondary stimulation of horses, rabbits, and guinea-pigs antitoxin is produced in the lymph-glands draining the injected area. As an example of the type of evidence they have produced, a horse was given a secondary stimulus of diphtheria A.P.T. in one hind leg and tetanus A.P.T. in the other; seven days later the tetanus/diphtheria antitoxic ratio was 10·5 times as great in an extract of the popliteal lymph-gland in the leg injected with tetanus A.P.T. as in the serum, whereas in a similar extract taken from other leg the diphtheria/tetanus ratio was 28 t that in the serum. They further showed that in certain circumstances antitoxin was produced in the skin at the site of injection. Nine months after the last stimulus in one horse concentrations of antitoxin were found that suggested continued production in the local lymph-glands but not in the injection areas. We still do not know what proportion of the total antitoxin is produced at the site of injection or in the local lymph-glands. Secondary responses with a considerable local production of antibody are not limited to injections made at or near the site of the primary stimulus. It follows that cells modified by antigen are carried to all parts of the body; they may all pass through the glands draining the injection area and only a fraction may remain. From a large initial dose of antigen far more reacting cells may reach all parts of the body and continue to multiply in their new specifically altered state. Because of this multiplication, the larger the initial dose of antigen and the longer the interval before the second injection the greater will be the secondary response. The size of a secondary stimulus has far less influence on the amount of antibody formed—very small injections may result in the rapid production of many thousand times the amount of antibody which would be equivalent to the antigen injected. The specificity of a secondary response shows that it is due not merely to a great increase in cells to deal with foreign protein but to a selective stimulation causing cells already specifically altered to multiply rapidly. It is not yet certain whether some types of primary stimulus may be followed by a good production of antibody but little basal immunity, whereas other types of primary immunisation may appear less satisfactory until a further stimulus is given. This might depend on the number of molecules of antigen taken up by each lymphocyte or other cell or on the rate at which the antigen is taken up, the rate of increase in number of the cells, or the capacity of the local lymph-glands to deal with this increase.

Many of the known facts about soluble antigens may eventually be explained by further work on the sites and methods of antibody production. The different capacities of individuals to produce antibodies, when the poor response is specific to certain antigens only, may be a result of initial stimulation by partially denatured or distorted antigens; an incapacity to respond well to all types of antigen probably results from some general defect in the reticulo-endothelial system. Rapid loss of antibody may be due to the initial slightly misshapen antigen becoming further distorted in descendants of the initial reacting cells. The latent period before antitoxin can be detected in the circulation is probably explained by the time required for sufficient generations of cells to be produced. It is well established that any attempt to hyperimmunise an animal too soon after primary stimulation results in the production of antibody poor both in quantity and quality. This is hard to explain, and the observation may prove of great value in the final elucidation of the causes and methods of antibody production. The study of the sites of antibody production may add to our knowledge of physiological processes and may also lead to methods of permanent immunisation providing

Annotations

REMUNERATION OF PRACTITIONERS

HE Minister of Health has informed the British ical Association that in his opinion “ no reasonable can be made for any increase in the total remunera- of general practitioners. nor any argument sub- tiated to show that general practitioners as a group inadequately paid. Nor, in his view. could any claim stified that any future alteration of remuneration ny later date should be made retrospective, either uly, 1948. or to the present day.”

INSULIN IN BUERGER'S DISEASE

Extreme remedies are very appropriate for extreme ases”—and there are few more desperate states than anced Buerger's disease. Curbed by intermittent dication, kept awake by severe foot pain. these ents suffer the crowning horror of ischæmic necrosis ch robs them of digit or foot or necessitates an above- e amputation. often with an ill-nourished. ulcerated mp. Fortunately the disease sometimes abates before ching this advanced stage ; and. attacking as it does n under the age of 50, there is some prospect of thwhile collateral flow and recanalisation if only the nding arteritis stops. Rational therapy is impossible e the cause of the disease is unknown ; and trial and r have accumulated a variety of therapeutic measures, h as sympathectomy, intermittent venous occlusion, therapy, intravenous hypertonic saline—to men- n only a few—none of which has established a very re place for itself. The most that can be said of of them is that remission of the active angiitis d improved peripheral blood-flow sometimes follow ir use.

n this issue Dr. Mazanek revives in modified form ethod of treatment first used nearly a quarter of entury ago by French workers who believed that rovement could be induced by the daily injection of 20 units of insulin. Dr. Mazanek gives much larger es (50–100 units twice daily for twenty days), his aim ng to produce for several hours each day a hypo- cæmia severe enough to cause symptoms but not the paired consciousness and convulsions which are the ective of the insulin treatment of schizophrenia. He ims striking improvement in 20 consecutive advanced es, with healing of trophic lesions, relief of rest pain, inished claudication, and warmer extremities. His ailed account of 5 cases is impressive ; the results are ter than could be expected from any other treatment d cannot be ascribed to the natural course of the ase. The follow-up period is only a few months, so is still doubtful how long the remissions will last. Mazanek shows commendable caution in pointing the beneficial effect of the concomitant rest in bed. he wisely avoids speculation on the modus operandi.

HOME MANAGEMENT OF PHTHISIS

DOMICILIARY treatment of the tuberculous, which has y been discussed in our correspondence columns, is sidered in more detail by Dr. Trenchard and Dr. tersall in articles which we publish this week. In ny large towns such treatment is now being under- ken, and recently Dr. Beatrice Butterworth and Dr. th Dingley[1] wrote on the complementary aspect of ome care as it affects the patient's family, giving weight the share the family doctor takes in the management the case.

The point which must be clearly brought home to the atient from the start is that he is being *treated*, and is ot merely “waiting for a hospital bed.” This means that e must realise that bed rest is in fact a form of treat- ent which would be begun in any case as soon as he went into a sanatorium. Once he has been convinced that he is “ working off a bit of his bed rest ” he usually becomes much more coöperative, and here the persuasion of his own doctor may be more effective than that of strangers. The range of active treatment which can be undertaken while the patient is living at home is remarkably wide. He may go into hospital for a few days for induction of artificial pneumothorax or pneumoperitoneum. or for phrenic crush or bronchoscopy ; but the first two can be done in the home in suitable cases. Even fluoroscopy can be done at home, with a portable apparatus. One task of the family doctor is to prepare the patient emotionally and by sedation for these events which appear so alarming to him, so trivial to the clinic staff. The family doctor is also the first on the scene in case of a hæmoptysis, and must resist the family's urgent demand that he should get the patient into hospital—explaining that it is better for him to stay where he is and rest, so that the bleeding has a chance to stop. If necessary the chest physician can come to him.

It would be foolish to suppose that domiciliary care is an advance on sanatorium care for the early case of tuberculosis : for however satisfactory it can be made for the patient it still carries some risk for the family. especially if there are young children or adolescents living at home. All agree on the necessity of a separate room for the patient, and where home conditions do not allow this the local authority will always help to provide better quarters. But, as Dr. Dingley notes, a separate room is not much use unless the patient stays in it ; and some young and discouraged people are difficult to keep there. The danger to other people. and especially the danger to children under five, is much reduced if the patient can be given even a brief period of sanatorium care before being treated at home. On general principles. however, children under five should not be exposed to infection from an open case in the home if this can possibly be avoided. If it cannot, there is a chance to use some ingenuity. A gate-door to the patient's room, Dr. Butterworth finds, keeps out small children and makes others think twice before coming in. Children of school age are less susceptible to pulmonary tuberculosis than younger children ; but they, and their much more vulnerable seniors in the late 'teens, may be unruly and hard to keep out. Dr. Butterworth advises that the patient's door should be locked while they are at home—but only if the patient is willing and has a duplicate key.

ANY COMPLAINTS ?

AT the start of the National Health Service, hospital management committees were too busy setting the new machine in motion to worry much about what its users thought of it. That phase. however, is over ; and committees are having to consider how they will face the public. There is little risk that the attitude of benign despotism which often prevailed under the old voluntary-hospital system will survive ; but there is perhaps some danger that the front which hospital bodies present to the public may be—or, what is equally grave, may seem to be—that of the bland bureaucracy which became familiar in the system operated by some local authorities. An impression of either despotism or bureaucracy must impair the chances of coöperation between hospital and patient and deter those who might otherwise actively help their local institutions : and, no doubt with this in mind, some management committees have been trying to meet the people they serve.

Last week the Lewisham management committee convened a meeting which was attended by representatives of the local community. “ I want you to feel,” said the chairman, “ that you are the shareholders of these hospitals. We shall not shirk any questions. We, as directors, will account to you as shareholders as best responsibility through the regional boards to the Minister is fundamental to the whole conception, while on the other hand it is necessary to provide for local independence. As things stand, the degree of consultation is left to the discretion of the regional board, but much turns on the exact procedure adopted. The letter of the law is satisfied if the hospital management committee is asked for names, simultaneously with the medical staff and the other parties mentioned: and the committee has, one supposes, no grievance if its advice is ignored. Surely it would be better if its rights were made clearer—e.g., if the regional hospital boards were required not only to obtain names from the hospital management committees but also to consult them at the final stage, and to allow them an opportunity to object to any members proposed to be appointed—other than the nominees of the medical staff, who should be appointed as of right. Is there any real reason why the hospital management committee should not be allowed this privilege? It would go far to reduce the possibility of persons getting themselves nominated—and for some theoretical reason appointed—who were sufficiently unsuitable to destroy the sense of cohesion essential if a hospital management committee is to work to full advantage. This is a matter to which the Ministry ought to give further attention, for any assurance that can be given here it will certainly pay a rich dividend in contentment in the hospital management committees.

---

Salmonella Infection

LAST year almost a thousand outbreaks of food-poisoning were reported in this country—twice as many as in 1945 and eight times the yearly average from 1935 to 1938. We can only guess at the total number of people involved, but it seems likely that *Staphylococcus aureus* had as many victims as all the 160-odd salmonella types together. Staphylococcal food-poisoning, however, is a brief if unpleasant encounter, and the self-limiting outbreak is more often caused by ignorance of the ways and means of infection than by gross lapses in cleanliness. With salmonella food-poisoning, or more correctly infection, the case is different, and man-to-man spread can only occur if there is neglect of personal hygiene. Salmonella organisms have been recovered from various unusual places but they are primarily intestinal parasites. The chief pools of infection are pigs and fowls, but rodents and ruminants also carry the organisms and carnivores and cockroaches are not immune. Man is not considered an important reservoir for the salmonellas—except those of the enteric group, which have failed to find permanent quarters in any other host. Many large outbreaks in this country have been traced to infected meat or eggs, but there are also very numerous sporadic cases in man which are difficult to fit into any convenient pattern of spread of the disease. Information is badly needed about the sources from which these apparently isolated cases become infected and what part they themselves play as reservoirs of infection in the community.

Apart from the acute cases of gastro-enteritis it is important to know how salmonella organisms are distributed among normal people. SELIGMANN et al.[1] isolated 26 different types from a large number healthy people in America, and this agrees with se other investigations which have shown that a 3% of apparently normal people may harbour th organisms. Most of the positives, however, we contacts of cases though they had no clinical sig of infection. Adult convalescents may continue t excrete salmonella for 4–16 weeks, but the short period is usual. MACKERRAS and MACKERRAS[2] foun that 35% of children under two years of age who we infected with *S. bovis morbificans* continued to excre the organism two months after infection, and t slower rate of clearance in infants (particularly *S. typhi-murium*) is known to pathologists in th country. Prolonged carriage is especially importa when children are crowded together in hospital, a there is still no good evidence that any of the ne antibiotics shortens the period of danger. It unusual to meet a permanent salmonella carri for the organisms remain in the bowel and are often transported in the blood to sites wh multiplication goes on unimpeded.

In this issue Dr. MACKERRAS and Miss PASK, Brisbane, contrast the low pathogenicity of what th term the endemic salmonella infections with the sev epidemic which they had previously encountered children. From 647 infants attending welfare clinics living in institutions they isolated 21 strains of salm nella, including 7 of *S. typhi-murium*. If these childr are accepted as a random sample of the child popu tion in Brisbane, there should have been 600 salmone infections in the city, whereas only 33 were trea in hospital. It seems unlikely, however, that th sample is random, and this type of argument fraught with difficulties. MACKERRAS and PA suggest that the pathogenicity of a strain is rai when virulent mutants are selected by passage fro one individual to another. With some other infectio there is much evidence for this hypothesis, but we st do not know what part an increase in the pathogenici of an organism plays in epidemic spread. They al believe that the dose of infecting organisms is le important than an increase of pathogenicity; b here again we are dealing with opinions. We do kno that foods (e.g., dried egg) originally contaminat with a few salmonellas may be eaten with impunit whereas if the same foods are kept under conditio where bacteria can multiply they can then cause explosive outbreak of disease. It is certainly true th infection with the salmonella organisms may be wi spread in the community without being suspecte and as in many other diseases the sporadic clini case may be something of an accident in a lo sequence of infection. As FRANCIS[3] reminds us, t frank case of infectious disease simply represents t crop line of a greater bed of infection in the famil cluster or group. People with symptomless infection missed cases, and carriers may excrete just many pathogens as the frank case, and becaus they escape their doctor's attention they are mo likely to hand on the disease. In seeking methods control we have to remember not only this underground spread but also the permanent animal po of infection from which so many outbreaks take thei source.

unaccustomed overuse of the pretibial muscles cause rupture and hæmorrhage in some fibres and se of tension in the anterior tibial compartment h, added to the usual swelling after exertion, pro- s increasing obstruction of the circulation to the cles and eventual ischæmia. This rise in tension is essential feature in producing the "muscle seques- ," so any factor which leads to such a rise may have same results: the instances after transfusion into leg veins were probably due to fluid leaking into the partment along the tendons. This explanation is reasonable, especially to those of us who have n a smart walk when out of condition and have rienced that agonising pain in the shins which ws. Diagnosis should not be difficult if the condition me in mind, but it is as well to realise that it is not tical with Volkmann's ischæmia, which is usually ciated with a fracture or other severe injury and affect every muscle below the knee.

is surprising that the syndrome is so rare, considering many young recruits nowadays take more violent cise than they are accustomed to. Any complaint ain at this site during exertion should be taken usly, and complete rest ordered if any induration is for spontaneous recovery is possible if paralysis not yet appeared. If paralysis does develop there ld be no delay in performing immediate surgical mpression of the whole of the anterior tibial partment by incising the deep fascia.

ASCITES AND HEPATIC CIRRHOSIS

E accumulation of ascitic fluid in quantities necessi- g repeated paracentesis is one of the most distressing ires of hepatic cirrhosis. Several factors are involved is disturbance of the normal balance between the compartments of the blood and of the peritoneal y, and much can be done to correct it, apart from t mechanical removal of the accumulated fluid.

rtal hypertension has for long been recognised as a mon sequel of hepatic cirrhosis, which favours the ation of ascitic fluid by increasing the filtration ure in the splanchnic capillaries. In the early stages rrhosis compression of the liver sinusoids by the fat- a liver cells probably plays an important part in the sis of portal hypertension, and relief of this compres- by the action of lipotropic dietary factors may unt for some of the clinical improvement obtained ietetic means. At a later stage the disturbances of hepatic circulation are of a more permanent kind[1] unlikely to be influenced by simple dietary measures. such a case, owing to hæmatemesis or other compli- ns, reduction in portal hypertension seems essential, urse must be had to some form of short-circuit ation such as anastomosis of the portal to the left l vein.[2] Owing partly to impairment of appetite, y to loss of protein in the ascitic fluid, and partly mpaired protein synthesis by the damaged liver, nts with hepatic cirrhosis often show gross dis- ances of their serum-protein. A pronounced fall in serum-albumin, with or without a rise in globulin, e most usual finding and is associated with a con- able fall in the osmotic pressure of the total serum- ein. This too favours the formation of ascitic fluid, several attempts have been made to influence it giving concentrated human serum-albumin intra- usly. The results have been almost uniformly dis- inting, and both Patek and others[3] and Faloon and rs[4] conclude that ascites is not primarily determined he plasma-albumin level but by alterations in water salt metabolism. Disturbance of water metabolism has recently been noted[5] in infective hepatitis, and recovery is often signalled by a diuresis. Ralli and others[6] have shown that this retention of water in hepatitis is associated with an excessive excretion in the urine of an antidiuretic agent which returns to normal when the patient recovers. The usually accepted explanation is that the liver normally inactivates the antidiuretic agent, and that in hepatitis and cirrhosis this inactivation may become impaired. Farnsworth and Krakusin,[7] moreover, have found that cirrhosis with ascites is associated with a well-marked retention of sodium and water despite normal renal function, which implies that the kidney is behaving as though the body were dehydrated. This too suggests that an antidiuretic factor is active.

With the mechanism of ascites formation so far elucidated it is not surprising to find that severe restriction of dietary sodium may result in a dramatic reabsorption of ascitic fluid. Layne and Schemm,[8] and Eisenmenger and others[9] have reported on two small series of cases in which severe salt restriction was followed by striking clinical improvement. In the cases of Eisenmenger et al. the critical level of sodium intake was 1·0–1·2 g. per day. With the intake restricted to this level for three months patients formerly requiring repeated paracentesis not only lost their ascites but could tolerate more or less normal quantities of salt. The serum-proteins in these cases also returned to or towards normal, partly because there was no longer a loss of protein into the peritoneal cavity, and partly because of improved protein synthesis by the liver. It seems therefore that, in many cases of ascites resulting from cirrhosis, sodium retention by the kidney, acting under the influence of an excess of an antidiuretic substance, is a major factor. Since in ascites, as in œdema, water follows salt, restriction of sodium intake restricts the retention of water. The actual reduction of already formed ascites, however, implies more than this. A daily intake of only 1 g. of sodium chloride leads to a slight negative sodium balance which after some weeks or months must reach a point where the production by the pituitary of the antidiuretic hormone is reduced. At this point a sudden rise in the urinary excretion of salt will occur, as Eisenmenger et al. noticed in their patients, and it is at this stage that reabsorption of existing ascitic fluid may be expected.

DISTRIBUTION OF AUREOMYCIN AND CHLOROMYCETIN

WHILE these two antibiotics are scarce and costly the Ministry of Health is purchasing all the available supplies and will distribute them through the regional hospital board centres previously used for distributing streptomycin; a list of the centres will be found in our news columns. Hospitals outside the National Health Service can obtain aureomycin and chloromycetin from these centres on payment. The arrangements will take effect from Nov. 21. For the present the use of these drugs will be restricted to the treatment of the following conditions:

Aureomycin.—Suspected cases of ornithosis; proved cases of undulant fever (brucellosis) and lymphogranuloma inguinale; and severe cases of atypical pneumonia in which there is good reason to believe that the cause is a virus.

Chloromycetin.—Suspected cases of ornithosis; proved cases of undulant fever (brucellosis), lymphogranuloma inguinale, typhoid fever, paratyphoid fever (severe), and salmonella septicæmia.

These categories may be added to from time to time in the light of current expert advice.

we can.” And so they did; the discussion ranged profitably over the deficiencies in the service which now irritate and sometimes dismay. Nevertheless, it may be doubted whether the meeting really fulfilled the intention of its sponsors. The hundred or so people who came included, as well as the committee itself, representatives of organisations directly concerned in running the hospitals and allied medical services, such as the regional board, the L.C.C., and the Emergency Bed Service; and an observation by a committee member on alleged laggardness by the regional board was a valuable reminder of the continuing need for those at the various levels to get together and argue out their difficulties and resentments. Plainly, however, this was not a business meeting to review coördination, for also present were spokesmen from a large number of local bodies. These are key citizens of a type from which the house committees and the management committee itself are recruited; and if the intention was to enlighten, and enlist the support of, this group then the meeting may be said to have succeeded. But, so far as the people of Lewisham were concerned, it was a meeting not of shareholders but of proxies. Questions and complaints could of course be addressed to the meeting through them; but not everyone belongs to a society or is prepared to have his case presented by a third party; there is no more personal affair than illness, and a reply at second hand, after this fashion, is surely likely to prove less satisfying than a direct note to, and answer from, the hospital.

These objections have been largely circumvented by the neighbouring committee at Farnborough. This committee serves a large semi-suburban district which includes Bromley, Beckenham, and Sydenham; and committee members have addressed public meetings and answered questions at three different points in the area. Often the questions or complaints were trivial; and thus current hospital administration was probably probed less deeply than at the Lewisham meeting. But each of these three meetings afforded the interested or the disgruntled a chance to address themselves directly to those actually administering the local hospitals—a process well calculated to promote interest and dispel any lingering impression of cold bureaucracy. In public relations further patterns will no doubt be evolved; and if, on the whole, the tentative design at Lewisham seems less attractive than that at Farnborough, it is better than no design at all.

MEDICAL BIOPSIES

Of late years great strides have been made in the techniques of aspiration, or needle, biopsy. Reviewing this field at a meeting of the Medical Society of London last Monday, Dr. R. Bodley Scott recalled that the wide practice of bone-marrow biopsy dates from 1929, when Arinkin devised the sternal-puncture needle; and with the single exception of the discovery of the liver treatment of pernicious anæmia, this, he said, is the most important advance in hæmatology in the past quarter-century. The sternum is the site usually chosen, though in children under 5 years and in patients with a hæmorrhagic state, puncture of the iliac crest is safer. One of the discoveries emerging from the growing practice of marrow biopsy is that myelomatosis is much less rare than was once thought—during the past year Dr. Bodley Scott has seen on average one fresh case a month. He went on to emphasise that marrow biopsy is indispensable before undertaking splenectomy for what is believed to be idiopathic thrombocytopenic purpura; for if marrow puncture shows no megakaryocytes the diagnosis is probably wrong and splenectomy will certainly be useless. He is somewhat reserved in his estimation of the value of lymph-gland biopsy, though it “will avoid the full operative panoply which surgeons deem necessary for excision of the smallest and most superficial lymph-node,” and it will often establish a diagnosis of carcinoma or perhaps of Boeck's sarcoid. Splenic ture has proved itself in the diagnosis of kala but, he suggested, it is not justifiable if diagnosis be made by some safer method. As regards “l puncture” in the diagnosis of neoplasms, this enta the risk of pneumothorax and of hæmoptysis, but th more serious alternative is thoracotomy. It is prob best to insert the needle under the radioscopic screen; bu if this is impracticable the tumour can be accurately loc ised by placing the X-ray film against the patient's che

Dealing specifically with liver puncture, Dr. R. Terry showed that among 3649 cases reported in rec years there have been only 7 deaths—a mortality 0·19%. Fully 90% of his patients feel no pain at t operation; and if they do have pain he attributes t to his own carelessness in applying local anæsthe The limitations, apart from the slight risk of fatali are: (1) failure to get a specimen; (2) the risk of obtai ing a specimen from a normal part of a liver whi elsewhere is abnormal; and (3) the difficulty of inter tation in very early and very late jaundice. Dr. Te listed the indications for biopsy under these headi (1) jaundice of uncertain origin; (2) hepatic enlargem of unknown origin; (3) malignant disease; (4) hep disease in which the diagnosis is otherwise difficu (5) obscure systemic disease where other diagnos methods have failed; (6) investigation of portal hyp tension, splenomegaly, and hypersplenism; (7) inves gation of the hepatic condition in constrictive pe carditis; and (8) evaluation of treatment in fat infiltration of the liver, [illegible] jaundice a infective hepatitis. To [illegible] added those cases where, 6–9 months after jaundic patients complain of lassitude and anorexia, witho other apparent disorder except possibly a rather lo serum-albumin; here biopsy may reveal continui hepatic disorder, which if untreated will progress b with treatment will clear up.

ANTERIOR TIBIAL SYNDROME

During the last few years there have been sever reports, mostly from the United States, of acute ischæm necrosis affecting the muscles of the anterior tib compartment of the lower leg after exertion. On anoth page, Barham Carter and his colleagues describe 9 simila cases in fit young men, seen in four British hospital In 7 of these severe pain in the shin came o during or soon after strenuous use of the limb—th right leg was affected in 5 of the cases—and was followe by signs of inflammation of the overlying skin and lo of power to dorsiflex the foot or toes. The other 2 patient developed symptoms after a blood-transfusion into th leg veins for shock following injuries to other par of the body. The affected muscles became hard an woody, and they were so contracted that the patien did not get a gross drop-foot deformity in spite of th loss of active dorsiflexion. With this there was complet lack of response to electrical stimulation in most instance a silent electromyogram, and the biopsy finding o ischæmia and necrosis. Sometimes, too, there wa evidence of a compression lesion of the anterior tibial nerve, causing anæsthesia in the first interdigital cleft on the dorsum and a reversible paresis of the extensor digitorum brevis. Of the three muscles in the compartment, the most vulnerable appeared to be extensor hallucis longus, then tibialis anterior, while extensor digitorum longus seemed most likely to escape damage.

Barham Carter and his colleagues review the various speculations as to the cause of the syndrome and feel doubtful about the general acceptance of arterial spasm or thrombosis as responsible; for later clinical, oscillometric, and arteriographic examination of the leg circulation reveals no abnormality of any kind. They believe uraging. It can only be hoped that appreciation of gravity of the situation may lead to sufficient nteers coming forward.

omiciliary treatment is a valuable adjunct which ease the problem, but is only a second-best when pared with true hospital facilities. It can at present completely with only a comparatively small part—between 10% and 25%—of the patients in need of tment.

y thanks are due to my colleagues and the staff of Harrow t Clinic who have taken part in the domiciliary treatment, to Miss Jewell and Miss Lacey who have assisted in king the figures for this paper.

HE HOME TREATMENT OF PULMONARY TUBERCULOSIS

W. H. Tattersall
M.A., M.D. Camb.
CHEST PHYSICIAN, READING

HE past fifty years have seen a greater expansion of lical knowledge than any previous period of history, this has focused attention on hospitals as centres the treatment of disease. Hospitals must always be eminent in the field of research, and for the nursing e of those who cannot be looked after at home: but re is no a-priori reason why any institution should itinue to be a place for the routine management of people if the proper treatment can be given in the mal environment of the patient's home.

During the past decade developments in tuberculosis apy have greatly extended the range of cases for om substantial benefit can be anticipated, and this st lead to either a greater demand for hospital beds else satisfactory treatment in the patient's own home. prime task for the present era of medical progress is apply the more complicated therapeutic devices outle the artificial and highly specialised atmosphere of e hospital. This is necessary because of the shortage nurses, but it is also desirable because the average glish home in the middle of the 20th century is a more itable place for medical treatment than it was twenty thirty years ago. Pioneer efforts in the domiciliary atment of disease are also being made outside the ld of tuberculosis; but, because the patient with thisis may occupy a bed for many months, the lead ven by various chest physicians in the London ea in domiciliary collapse therapy is especially luable.

Real rest is an essential in the management of phthisis. owadays, however, when more and more patients may nefit from collapse treatment or chemotherapy, it is ually important that the physician in charge of the tient shall not remain contented to add a name to a aiting-list that may entail many weeks' delay, but shall t about forthwith preparing every suitable patient for propriate collapse treatment at the appropriate time. ccessful treatment is the more successful if it can be ective with the minimum delay; this is not to vocate the so-called "crash pneumothorax" but to plore the almost nonchalant attitude that sometimes ists toward the ponderous waiting-lists for some natoria. Masterly administration could do much to leviate this situation immediately.

ARRANGING CARE AT HOME

Most people have a home, and most families are ually glad to participate in the care of a sick relative, they can have help and guidance. Care must be ken, however, to choose the right case for domiciliary easures. In the first place, the tuberculosis health isitor should visit the home as soon as possible after iagnosis to make a tentative assessment of the practicability of nursing the patient there, paying particular attention to certain aspects of the household. There should be two relatives or close friends (one at least living in the house) of suitable disposition to care for a sick person. The patient must be able to have a room to himself or herself suitable in size and outlook for prolonged bed rest without overcrowding the rest of the household excessively. Toilet and washing facilities must be easily accessible. The house must not be too remote for the physician to answer a summons to an emergency.

If conditions are favourable for home treatment, and the patient's own doctor agrees, then the welfare officer should make the necessary arrangements to maintain the economic stability of the family, with provision of home helps where necessary, boarding-out of children, and perhaps "meals-on-wheels." The guiding principle should be that since the patient is relinquishing his claim to "*free*" hospital treatment, he must not be financially penalised. Since the bed resources of the State are being relieved, the State should assist the family finances appropriately. Some financial adjustment may be necessary between the regional hospital board, the local health authority, and the National Assistance Board: but that need not concern the patient.

The tuberculosis health visitor should call frequently at first to teach the regimen. She has to answer the family's questions, to plan rest-hours, to put a check on sympathetic visitors, and above all to teach the patient the art of resting—which has been forgotten in the hurly-burly of modern society! The help of the district nurse can usually be enlisted to keep the patient's chart and to explain to the responsible relatives their part in the nursing work, which can well be left under her supervision. "Absolute" rest is out of place in the home, and the case for which this is really necessary merits a week or two's priority of place in hospital. Diversional therapy should be arranged when this is prescribed. The physician should make a weekly visit as a captain inspecting his ship (sometimes in company with the general practitioner if possible), and these weekly calls should be a regular feature of management quite apart from whether necessary later on for refills. Whether a pneumothorax should be started at home, or the patient have a week or two in hospital is a matter for individual judgment, as is the question of managing refills wholly at home or using the hospital car service to bring the mountain to Mahomet for screening control. Some physicians carry portable fluoroscopy apparatus, and though this slows their travelling-rate, and therefore the number of cases that can be visited in a session, it enhances the standard of medical care that can be given. Streptomycin can be perfectly well given diurnally by the district nurses, who usually welcome the opportunity to assist in such work. Pneumoperitoneum refills can be given at the physician's weekly visit. The patient must go to hospital for thoracoscopy or phrenic crush, but after two or three weeks for the former, or days for the latter, he can usually return home.

Behind a programme of home treatment must be the safeguard of a vacant hospital bed ready at any moment to take in the patient who should need it. Mother may get flu, a complication may supervene, or the physician may decide that the experiment (for every case should be regarded as such) is not proving successful. Some patients settle better with a short initial period in hospital. It must be a sine-qua-non that the physician conducting complete initial home treatment for tuberculosis will have hospital beds under his immediate control.

REGIMEN AND MORALE

One can never satisfy the querulous that home treatment can be as effective as disciplined sanatorium

Special Articles

THE TUBERCULOSIS SITUATION

WAITING-LISTS AND DOMICILIARY TREATMENT

H. J. TRENCHARD
M.B. Birm., M.R.C.P., D.M.R.D.
ASSISTANT SENIOR MEDICAL OFFICER, NORTH WEST METROPOLITAN REGIONAL HOSPITAL BOARD; CHEST PHYSICIAN, HARROW CHEST CLINIC AND EDGWARE GENERAL HOSPITAL

IN many parts of the country the position of the tuberculous patient is becoming desperate. The following observations on the position in one region and in one of its chest clinics may illustrate the state of affairs. In the Metropolitan regions some of the worsening of the problem is due to the fact that a large number of beds in the provinces, which were formerly used for patients from the Metropolitan area, are now required for local patients.

A REGION

The population of the North West Metropolitan hospital region is estimated to be about $3\frac{3}{4}$ million. So far as can be ascertained, the number of cases of respiratory tuberculosis on the chest-clinic registers in the geographical area at the beginning of 1948 was at least 21,000, and on Dec. 31, 1948, it was over 22,000. Allowing for removal of cases through recovery, death, change of residence, &c. there was therefore a net increase of about 4·7% in the cases known to the chest clinics, and probably there will be an increase at least as large during 1949. On Dec. 31, 1948, the waiting-list for admission contained nearly 1250 names; by September, 1949, the list had risen to approximately 2000. The hospitals of the North West Metropolitan regional hospital board have about 1850 beds for pulmonary tuberculosis, and a further 300 patients are still in hospitals not belonging to the board. The number of annual deaths from respiratory tuberculosis for the region (calculated from the latest figures available for London and Middlesex) is approximately 1650. Instead of the $2\frac{1}{2}$–3 usually regarded as adequate, the region has in fact for its use about $1\frac{1}{4}$ beds per annual death.

It can be seen, therefore, that 0·6% of the population of the region is known to the chest clinics—a proportion tending to rise at the present time by over 4% per annum. There are over 3850 tuberculous cases in need of hospital type treatment and only 2150 beds in which to treat them.

Much has been said recently about the necessity of bringing hospital care into the home. This has applied particularly to the chronic sick and to the aged. Much has also been done for the tuberculous on similar lines; but it must be remembered that many cases of tuberculosis are treatable and should be classed as acute and not as chronic sick. It is necessary to make use to a considerable extent of the services provided by local health authorities—e.g., welfare work, home nursing, home helps, car transport of patients for radiography, bedding and nursing requisites, boarding-out of children, and domiciliary occupational (recreational) therapy. Unfortunately, however, in many counties a charge is now made for some of these services, which were formerly provided free. A number of chest clinics in the North West Metropolitan hospital region have schemes for domiciliary treatment, including collapse measures. Their scope depends on the staff and facilities available at the various clinics.

During $7\frac{1}{2}$ months, 1666 names were removed from the regional waiting-list: of these 1214 patients were admitted, 69 died awaiting admission,* and 204 removed as "refused treatment," or "removed region"; but 179, as a result of domiciliary treatment a period of up to eight to nine months, had progre sufficiently well for the application for hospital admissio to be cancelled. This, from the point of view of patient treated, equals in value one of the smaller chest hospita of, say, 180 beds.

A CLINIC

Harrow Chest Clinic serves a population of ov 200,000. In October, 1946, when it first became a independent clinic, the number on the register was 37 It is now 1440. Some, but by no means all, of th increase is due to the development of a new Lond County Council housing estate in the area, where som tuberculous families are given priority in rehousin The number of patients awaiting chest hospit (sanatorium) admission at present is 109.

Our policy is to plan the management of the ca —from the medical, social, and preventive aspects—o comprehensive lines and to arrange that suitable tre ment is given while the patient is awaiting admissio In some cases domiciliary treatment may result admission becoming unnecessary; in others the patie enters hospital with the initial stages of his treatme over; in yet others unfortunately little can be done o a domiciliary basis, particularly when the patient uncoöperative, or the home conditions (lodgings f example) cannot be made satisfactory. To provide suitab basic conditions it is necessary to rely to a considerab extent on the local-authority services already mentione The medical measures employed at home are first rest, reinforced by posture, avoidance of coughin pneumoperitoneum, phrenic crush as an outpatient occasionally pneumothorax, and *p*-aminosalicylic ac as is appropriate. Some patients are admitted to th very limited number of beds under the direct control o the chest-clinic physician, for the minimum practicabl length of stay, for other methods of treatment (e.g. induction of pneumothorax or administration of strepto mycin). As a by-product, the environmental aspects o the case probably receive even greater attentio than they would if domiciliary treatment was not undertaken.

Adopting these measures, of 153 cases put on the waiting-list during a twelve-month period, 27 have improved sufficiently to make sanatorium admission unnecessary.

These figures are given to illustrate the position with which tuberculosis physicians are faced today. The clinic domiciliary-treatment results must have been bettered elsewhere. The achievements of other chest clinic physicians—some of them near neighbours—excite envious admiration. The greater use, in suitable cases, of domiciliary artificial pneumothorax has much to recommend it, but requires courage and a nice judgment, for in unskilled hands it is potentially dangerous.

CONCLUSIONS

Tuberculosis is primarily a disease of young adults, economically probably the most valuable section of the population. In consequence, and because of its prevalence, it is the most important single disease with which at present we have to deal. The situation of its victims is a very serious one, which appears to be becoming worse because of an increase in the numbers requiring treatment.

The beds available are *fantastically* inadequate; and, owing to the difficulties of finding nursing staff, the prospect of opening an adequate number of beds is far from nt—shall I say ?—" examinee." This type can be ised in thirty seconds. The thing to do then is me a question requiring a lengthy answer, such as cribe the gastro-intestinal tract." The weary ner can then snatch four minutes' complete relaxa- nd be fighting fit when the bell goes for the next date. I was amazed when one such nurse (I mean nee), asked to describe the formation of urine, d out, "Oh, I'm so glad you asked me that! een willing you to do it." Shades of the Piddingtons! as a bonny girl (and I don't mean examinee), and h I stuck strictly to the syllabus she was blushing she went out. I wonder if there *is* anything in this ht-transference business ?

---

* Of these 36 were hopeless cases when put on the waiting-list.

grounds of the hospitals where the examinations eing held are plentifully signposted with the word the State Examination," complete with little arrow. s happened that outpatients have been misled in ay, and have presented themselves for examination Prelim room. One old lady, indignant and voluble, eard to demand a private examination. " Nobody's ; to State examine me," she shouted, as she was way to the proper place.

m always grateful to the sister tutors and hospital who so ably cope with the steady flow of candidates ply the wilting examiners with frequent cups of tea. too must be glad when the bell goes for the last d, and the examiners fold up their papers and steal , leaving the hospital to the comparative peace normal routine.

fine sense of exhilaration possessed us four boon panions as we ambled along through East Anglia he crisp clear November air. Crowded surgeries, ficates, and " bob prescriptions " mattered not at Soon, but not too soon, we had thirsts and appetites ming English gentlemen and were glad when we pened on a goodly hostelry. As we filed into the cosy less dining-room a big log fire in a Gothic arched fireplace gave a more than friendly welcome, and menu—mushroom soup, jugged hare with red-currant , biscuits and Stilton cheese—and a pint of local r bespoke a gracious meal. Looking around for the ter to take the order, we became aware that there was servery to the dining-room but only two entrances ectively marked *Ladies* and *Gentlemen*. In answer the bell an immaculate waiter emerged through the *tlemen* (fair enough !). Having placed the order we ld wash our hands ; still one of the graces before at. We opened our door and discovered " It " immedi- ly through a door to the right, while the kitchen and very occupied the opposite wall beyond. On the job chuckled, rather self-consciously I admit, for we well lised that our D.P.H. was now rather shabby and moded, derived as it had been by way of miasmas, demiology, and sanitary science, whereas this is the of positive health, gerontology, and social medicine. adwick rather than Ryle was our mentor. When we urned to the dining-room the most venturesome mber of the party could not resist the impulse to en the *Ladies*, but, confronted only by a flight of stairs, ready words " Sorry, Sir " died on his lips. There- er followed a merry lunch during which all agreed t the English hostelry still retains an indefinable mosphere. Quite by accident we had enriched our ech by a new idiom. And so, after the port and coffee your panel cheque still permits such hospitality to ur friends) : " Before we join the ladies, would any of u gentlemen like to see the kitchen ? "

* * *

They'd all gone and I was propping up Miss Joanna alker's R.G.50 against the ashtray when the waiting- om door opened and in he popped, the grocer's lad. simpleton, so 'twas said. " Do ee treat they Land irls at Moor House ? " he asked. " Yes, why ? " Do ee know Daisy ? " " Daisy who ? What's her urname ? " " That be what I want to find out." Why ? " (I didn't like the sound of this. The usual rouble I shouldn't wonder.) " 'Cos I want to send 'er postcard." I was sorry I couldn't oblige. But I must ell Daisy she has a smart lad as an admirer.

Letters to the Editor

REHABILITATION

SIR,—Rehabilitation is a popular word today ; but to most of us it remains no more than a word tacked on to the trilogy of Diagnosis, Prognosis, and Treatment. It should mean much more to every doctor practising clinical medicine. Despite our excellent schools of physiotherapy, it is still only too common to meet and hear of patients whose invalidism is increased because doctors ignore the principles of rehabilitation.

In a recent lecture, Dr. Howard Rusk, of New York, emphasised that the first aim of rehabilitation should be to make the patient independent. This may seem obvious, but unless we devote more time and work to making sure that each patient is helped to use his *remaining powers fully and imaginatively*, it cannot be achieved. Our aim must be to concentrate on details of the care of patients which will enable them to lead an independent and profitable life with minimum disability. When this aim is realised, perhaps one will not find in a top-floor room a young recent hemiplegic, with a reasonable prognosis for life, attending a London teaching hospital for electrical treatment, who has had no re-education in walking or speaking, whose joints are stiff, and who has never been given a stick to help him walk. Perhaps then one will not meet an adult who has lately had poliomyelitis, leaving him with an extensive trunk weakness, whose only treatment in an orthopædic hospital was a weekly communal-exercise class and who was discharged more or less straight from bed with no trunk support, no aftercare suggestions, and no introduction to the difficulties of resuming life at home. Perhaps then one will not read in your disability series of a doctor with a minimal spinal fracture having no physiotherapy and being quite unnecessarily confined to bed and an invalid's life for some months.

It is not only in such orthopædic cases that rehabilitation can help the individual and the community. For example, instruction in simple abdominal exercises and postural exercises can remove the need for thousands of specially prescribed corsets ; perineal exercises after delivery can restore the normal function of the pelvic floor, and save much misery. The list is long. The lesson it teaches is that it is a doctor's responsibility to teach his patients how to help themselves. Where patients have the good fortune to be cared for by enlightened doctors and good physiotherapists, their whole outlook is altered and their prognosis for effective recovery immeasurably improved. We must have more contact with our patients. Today I believe there is a temptation and a tendency to leave the patient's side and study the problem from afar.

Rehabilitation calls for the direct relationship—the human touch and the infectious determination which will animate patients and society and convince them that *restoration of function for big and little disabilities is* worth doing and can be done.

London, N.2. JEAN LAWRIE.

THE DISTINCTION AWARDS

SIR,—Dr. Walshe says that " To allow government to be our principal paymaster is one thing, but it is quite another to permit it to impose upon us a crude, arithmetical classification of all those imponderables that make up true distinction in our profession." But are we doing so ? If we look objectively at the proposed terms, a part-time consultant, professionally assessed, will earn from the Government by doing hospital sessions paid at a rate based on representations made by the profession to the independent Spens Committee. He will earn also by domiciliary work according to his merit in the eyes of general practitioners. To this may be routine. The newly diagnosed consumptive has a difficult phase of psychological adjustment to his disease, and one of the most important aspects of his management comprises wise and helpful guidance through this stage. Admission to sanatorium or hospital and contact with other patients or staff familiar with the new mode of life, may, (or may not!) help a great deal in attaining the necessary reorientation. A retreat is provided from the problems of everyday life which is of real therapeutic value in some instances. On the other hand, a patient can benefit greatly from the satisfaction of a loyal family rallying to his succour, and the determination to recover may be better fostered in such an atmosphere. It is a very real criticism of the present tendency to retain patients in sanatoria for many months that such prolonged segregation from the realities of life may engender a sense of lost social security on discharge. Such a dependent outlook on life readily leads to hypochondriasis, family disagreements, and a fear of resuming work, all of which detract substantially from the benefit of successful treatment for the purely organic aspect of the illness.

* * *

It should be a sobering thought for every tuberculosis physician that if a quarter of the treatable cases he diagnoses (a conservative estimate) could adequately have three-quarters of their treatment at home, sanatorium waiting-lists would disappear and a bed would be immediately available for every patient whose illness required it. It is well for us to remember the end, as well as the beginning, of Hippocrates's famous aphorism:

> "It is the duty of the physician not only to do that which immediately behoves him, but to secure the cooperation of the sick, of those in attendance, and all external agents."

NEW HEALTH DIRECTOR IN NEW ZEALAND

FROM OUR NEW ZEALAND CORRESPONDENT

THE impending retirement on superannuation of Dr. T. R. Ritchie, who has been director-general of health for three years in succession to Dr. M. H. Watt, has led to the designation as his successor of Dr. John Cairney by the Public Service Commission. The appointment is subject to the usual public service appeals. The commission was advised by a special committee consisting of Sir Charles Hercus, Dr. E. H. M. Luke, Mr. Douglas Robb, and Mr. P. E. Stainton.

Dr. Cairney, who is 51 years of age, is at present medical superintendent-in-chief to the Wellington Hospital Board, in whose service he has been since 1936. Previously he was medical superintendent of Hawera Hospital, and still earlier, demonstrator, lecturer, and finally associate professor of anatomy in the Otago medical school. He thus approaches his new task with full experience—and a great reputation—in the hospital field. This is recognised as at once the largest field within the department's duties, and the one requiring most attention. For years the machinery has been creaking, and coördination between the department and the local boards has been inadequate.

Dr. Cairney faces a formidable task. Not only the hospital system but also the hygiene work throughout the country needs improved conditions and organisation. In addition there has never yet been set up a structure to handle the numerous and important matters arising out of social-security legislation in New Zealand—now almost ten years old. His plans, therefore, will be followed with interest and hope by many. He has a great opportunity for achievement, and he has the general good will of the profession and the public behind him.

In England Now

A Running Commentary by Peripatetic Correspo

THE doctor on the telephone was worried. "I'm they must come in; they're not unconscious but they' ataxic, talking rubbish at the top of their voices, an quite uncontrollable." They were admitted as emergencies—two nice little boys, brothers, of eight and te When the H.P. saw them their condition had changed t extreme somnolence. There was no doubt about th previous condition, however, for their father gave good history, summing up by saying, "Of course I kno it couldn't be, doctor, because they've never ev tasted it, but it seemed just as though they we drunk."

Further inquiry established that an hour before the illness started the district nurse had given them both a infusion of quassia enema for threadworms. It seeme innocuous enough; but our H.P. pursued the subject an found that there are two infusions of quassia—o containing alcohol. The chemist dispensing the infusi hadn't known what it was for, the doctor hadn't specif which (did you know there were two?), so they rea were under the influence. They were much better n day, though they had rather a morning-after look abo them, and we all felt a little sorry that they hadn't ev had the pleasure of drinking the stuff.

Perhaps there is compensation in being the first have this complication of threadworms, and perhaps th first to become drunk per rectum. But were they drunk Or does the term imply that the alcohol was swallowed I must find out, too, what happened to the threadworm

* * *

Thank goodness that the oral examinations for th G.N.C. "Prelim" are to be abolished. I am convinced tha the fee I earn for examining in them does not compensa for the disruption of my ordinary medical work, the travelling, the living in hotels, the physical strain of bein immobilised on a (usually) hard seat for several hours o end (so to speak), and the mental strain of trying to co answers from unresponsive candidates. And it is astonishing how unresponsive many of them can be. At one time, used to think this shortcoming was due to large classes o indifferent teaching, but now I am sure that the inability of candidates to satisfy the examiners (and some ar satisfied with little) is due to lack of concentration on and interest in, the subjects to be studied. How els can one explain such staggering errors as "the femu has an atmospherical head"; "the anus is guarded b a spinster"; "the cows are examined by a tuberculou veteran"; and "one of the pigments is called biley virgin." In some years of teaching experience I have found only a mere handful of nurses who lacked the necessary intelligence to pass the Prelim. These can be excused. The real heart-breaking failures are the ones who could do well, but who "couldn't care less."

Only twice have I had candidates who scored no marks at all in anatomy and physiology, though in all fairness I should add that one of them correctly identified a large and life-like model of the human eye. The rest was silence and darkness over all.

The following conversation, which took place in a recent "oral," is a good example of cruelty to examiners

Me: "What germs might be found in contaminated water?"

Candidate (after deep thought): "Bâcteria."

Me: "Well then, what bacteria might be found &c., &c.?"

Candidate: "Micro-organisms."

Me (determined to see this through): "Well, what micro-organisms, &c., &c.?"

Candidate (triumphantly): "Germs!"

This is where I came in, I thought, as I passed her over to my colleague—a gentle middle-aged lady—who was soon informed that to pasteurise milk "you boil it at 105° to kill the bacteria," but with commendable restraint she did not fall into the trap by asking "what bacteria."

As a welcome relief from the girl (the G.N.C. says we must not say "nurse") who does not know the ischial tuberosity from the olecranon, comes the rare and n in coal workers,[5] differs in all the main pathological res (pigmentation, fibrosis, and focal emphysema) the true silicotic nodule as seen for instance in miners,[6] who inhale a dust predominantly siliceous mposition.[5] Airborne dust in South Wales coal- s and graphite contain relatively minor amounts of silica.[3 7] Although it cannot be denied that free may play some part in the genesis of pure dust is in coal workers and graphite workers, the *direct* of the major carbonaceous fraction of the inhaled must not be ignored. The most reasonable view s to be that simple pneumoconiosis in graphite as as coal workers is the result of a prolonged over- ng of the pulmonary mechanisms for disposal of culate matter by a dust which is largely inert in ct of tissue-reaction to it.

cordingly it is suggested that the massive lesions aphite workers are infective in nature and that the l, black, focal lesions scattered throughout the lungs ot represent a form of silicosis modified by a so-called terant dust but rather the response to overloading te lung with a predominantly carbonaceous dust h induces little fibrosis.

HOSPITAL ADMINISTRATORS

R,—I cannot allow to pass unchallenged the arrange- t of the table, in your note last week (p. 923), showing in the Bromley group the administrative staff unt to only 1·27% of the total. Why are the 105 cal staff shown in a different section of the table? ly in the past our clerical departments, in whatever k they may have been engaged, have been regarded ne of our administrative charges when the annual pital costing has been prepared for submission to appropriate committee. Most of us are prepared to cede that there are good points both in medical and ay administration; but if we are to be presented with stical evidence, surely the figures chosen must be ctly comparable.

urthermore I feel that some clarification is needed as he exact interpretation to be placed upon the state- nt that "there may still be some superfluous ministrators in our hospitals." It is not clear whether s is an opinion expressed by the writer or a comment his report, but I am sure he will not feel aggrieved if sk whether medical superintendents are included ongst the redundancies. This point of view has been lely expressed during the past few years, but I often nder whether some of our younger lay administrators lise the extent to which they are now profiting from ir inheritance of hospitals for which some of the older dical administrators have been largely and personally ponsible.

Many of my colleagues will agree that in the days when were governed by boards of guardians, and to a tain extent under public assistance, medical adminis- tion was really tough. Often it was necessary to fight our hospitals and our patients in the face of the ost rigid economy. I well remember how I was once ked to explain in front of the full board why an instru- ent costing 8*s*. 6*d*. was essential for my small impro- ised theatre; now we have four major theatres in most constant use for which requisitions are never uestioned. For several years I was not permitted to old an antenatal clinic on the grounds that it would courage mothers to apply for hospital admission; ow we have an obstetric department which is regarded s one of the finest in the region.

To obtain improvements such as these involved long, wearisome, and often singlehanded contests extending over many years; and those who have been largely responsible should not I think be so lightly relegated to the limbo of the past as just "some of our superfluous administrators."

JOHN F. HACKWOOD
Chairman of the Medical Superintendents' Society,
London and Home Counties Branch; Surgeon-
Superintendent, Farnborough Hospital, Kent
(Bromley Group).

⁂ The table to which Mr. Hackwood refers appeared originally in the Bromley Group Hospital Management Committee's report for the period July 5, 1948, to March 31, 1949. The comment on "superfluous administrators" was ours, and it went on; "but it seems that the emergence into the management-committee's offices of clerks and others who formerly worked unseen in the local authority's medical division gives a faulty impression of fresh exuberance of numbers." We were considering only the apparent increase in office-workers, which in some hospitals has been the subject of adverse criticism by the medical staff.—ED. L.

INTERPRETATION OF VAGINAL SMEARS

SIR,—In their interesting article of Oct. 29 on the correlation of vaginal smears and mammary cancer, Dr. Walpole and Dr. Paterson have coined a new term— "mean smear index" (M.S.I.)—to signify the degree to which the vaginal mucosa is stimulated by œstrogens.

Since the normal menopausal smear may contain a preponderance of small or immature cells or, more commonly, a mixture of more mature cells, the starting-point must vary from case to case. The estimation of the degree of reaction or maturation for a given dose of stilbœstrol must therefore be different although the final cell smears may both be typical "stilbœstrol" smears.

The use of the "M.S.I." and the arbitrary use of numbers (index 0 up to 9) imply a precise knowledge of the degree of development of the mucosa. But consider the source of this index number. It is the mean of the impressions of maturity gained from examining several fields of smears on the first and sixth (or other) month of treatment. To me, therefore, M.S.I. means very little.

HUGH C. MCLAREN.

FREEDOM UNDER THE LAW

SIR,—The *Times* of Oct. 27 contains a report of Lord Justice Denning's third lecture on Freedom under the Law, in the course of which he is reported to have said that if doctors and dentists under the National Health Service injured their patients through negligence, the State would be liable to pay damages.

My contacts with medical men and lawyers lead me to think that the learned Lord Justice's observations are being misinterpreted by many members of the medical profession and are receiving a far wider construction than they can properly bear. It is wrongly assumed that a liability in the State to pay damages means an exclusive liability, and that the doctor or dentist, being relieved by the State from the personal liability which would otherwise attach to him in case of negligence, need no longer take the precautions which have hitherto been customary to guard himself against the risk of being sued for damages.

I therefore desire to emphasise that although in some cases there may well be a liability in the State, the doctor or dentist himself is also liable to be sued and probably will be sued concurrently, since the plaintiff gains certain technical advantage in having him as a defendant.

Unhappily the matter does not stop there, because the Ministry of Health have declared it to be their policy

added a merit award according as his fellow consultants judge him, and there will be added private work according to his professional standing. The sessions, domiciliary work, merit award, and private work which fall to him will depend upon his qualities of various kinds; and the final answer will be a function of four variables, flexible, far from crude; and, within the total that the Government feels expendable, determined very largely by professional arrangement and judgment.

Such analysis of the reward of the toiling human spirit in the field of medical science may seem repugnant. It is therefore worth while to refer to the leading article in *Nature* of Nov. 5, which speaks of the neglect not only of the medical but also of other professions to consider the problems which nationalisation presents to them, clearly delineated many years ago. It is notable that the article quotes Prof. A. N. Whitehead's criticism of the professions; and as, in his Harveian oration, Dr. Walshe said that he owed much to that philosopher, it is worth recalling what Whitehead wrote:

> "In the past," he said, "professionals have formed unprogressive castes. The point is that professionalism has now been mated with progress. The world is now faced with a self-evolving system which it cannot stop."

Had Dr. Boldero or Dr. Russell Brain written this, what would have been Dr. Walshe's devastating reply? And yet there can be only one answer—the answer of the colleges and the writer in *Nature*—that professional men "must accept a major responsibility for establishing and improving the channels of communication between knowlege and power and keeping them manifold and clear." To reject that responsibility is the real treason; and the worst retreat the profession can make is the retreat from reality.

ACUTE MASTITIS

SIR,—I have followed the correspondence on this subject with interest. We, in the veterinary profession, have a considerable experience of this condition in the dairy cow, for it is regarded as one of the four major diseases afflicting the dairy industry. For instance, in these laboratories we have examined bacteriologically since the beginning of the year over 750 samples of milk from clinical cases of bovine mastitis in one veterinary practice alone. It is for these reasons that I should like to correct certain statements in Mr. Hogg's letter of Oct. 22 which I consider are misleading.

Although Mr. Hogg suggests that direct infusion of penicillin up the teat canal is preferable to systemic administration, he implies that it is still not settled whether the concentration achieved in the udder by systemic treatment is as satisfactory as that following teat infusion. Yet reports quite unequivocally agree that when penicillin is administered systemically (unless in enormous doses) practically none can be demonstrated in the milk; whereas when penicillin is injected directly up the teat canal, appreciable concentrations can be measured in the milk. The persistence of penicillin in the udder is influenced to some extent by the penicillin vehicle, and by the stage of lactation.

While I agree that it is a common farming practice to allow calves to suckle cows with mastitis and that it may be a sound treatment as far as the cow is concerned, I cannot but doubt whether it is sound to feed young calves on a mixture of blood, pus, and micro-organisms. Admittedly the calves appear to thrive, but one wonders how their bacteriological flora is affected and whether it may have any effect on their subsequent history as far as mastitis is concerned. We do not know, and it would take an elaborate and protracted experiment to provide the answer.

Finally, it would be most unfortunate if Mr. Hogg's letter gave the impression that penicillin preparations are directly available to farmers. The use of in the veterinary field is governed by exactly the legal safeguards as in the medical field—namely, terms of the Penicillin Act, 1947. In veterinary penicillin may be used only under the su the prescription, of a veterinary surgeon. Direct sup of penicillin to a farmer by a chemist without a veterin surgeon's prescription is against the law.

GRAPHITE PNEUMOCONIOSIS

SIR,—In your leading article of Sept. 17 attention drawn to the conclusion of Gloyne, Marshall, and Hoy and of Harding and Oliver[2] that graphite pneum coniosis represents a modified form of silicosis due the inhalation of a dust composed largely of carbonace material mixed with a small amount of free silica (of t order of 10% according to Harding and Oliver). The investigators draw an analogy between the pneum coniosis of graphite workers and that occurring coal workers.

From the descriptions and illustrations two typ lesion can apparently be recognised in graphite pneum coniosis. The first of these appears to be a small fo collection of black pigment with little fibrosis and distinct focal emphysema surrounding the pigment area, such lesions being scattered evenly througho the lungs. The second type of lesion is a pigment mass of dense fibrous tissue, often several inches acro tending to be situated in the upper and posterior pa of the lung and sometimes showing colliquative necro These latter lesions do not show obvious evidence tuberculosis.

Respectively the two types of lesion in graph workers correspond closely to the simple and infect forms of pneumoconiosis seen in coal workers.[3] Neither Gloyne and his colleagues nor Harding a Oliver, however, discuss the possibility of some lesio being due to the action of dust alone and others to t combined effect of dust and infection. The eviden justifying such a distinction in the disease of coal worke has already been presented, and, despite the absen of obvious tuberculosis in some massive lesions, reaso were adduced in favour of a tuberculous origin for them If the "conglomerate," "mixed," and massive lesion described in graphite workers were basically silicotic i nature (i.e., due primarily to the action of inhaled fr silica particles), they would be expected to assume much more uniform distribution, since inhaled du is deposited evenly throughout the lung parenchyma and to partake of the character of silicotic nodule (see below). Instead these lesions are restricted i location to areas of the lung commonly affected b chronic tuberculosis in those who have not been expo to an occupational dust hazard. Furthermore whorlin of fibrous tissue is not necessarily indicative of th action of free silica, since exactly similar effects may be produced by "healed" tuberculous foci. It thus seem that massive lesions in graphite workers should be regarded as infective in origin. Your leading article does refer to "massive progressive fibrosis of the lung superimposed on dust reticulation," thereby suggesting that the two manifestations are distinct, but no indication is given as to the nature of this distinction.

An argument against silica being the essential agent in the production of simple pneumoconiosis in both graphite and coal workers lies in the nature of the characteristic focal dust lesion. The latter, as already

ANTIBIOTICS AND COAGULATION

t,—I should like to correct the impression, which annotation of Oct. 22 (p. 756) may have given, we have done any work on the influence of antis in thrombo-embolism. The presentation which de before the International Surgical Society was based alysis of 7 years' experience at the Charity Hospital ew Orleans. We have been interested in thrombolism for more than a decade and have felt that we able to prevent most cases of venous throm-, and to prevent fatality in those cases in which d occur by recognition of the phlebothrombosis and ion of the vein proximal to the site of the thrombus. were astounded, however, in our analysis to find there has been a tremendous increase in the incidence enous thrombosis and fatal pulmonary embolism he Charity Hospital in spite of all the measures h we have undertaken to prevent them.

ie study showed that there was an increase in the age yearly incidence of thrombo-embolism from o 124 during a period when the admissions increased 20%. The number of fatal cases of pulmonary olism in the last two years is approximately the e as in the previous five years, which represents an ase in the average yearly incidence from 20 to 52.

his study demonstrates that thrombo-embolism has nitely increased. Though we have not yet been able rove it, the suggestion was made that the increase hrombo-embolism might be due to the almost routine ninistration of antibiotics to hospitalised patients; at t, there is a parallelism between the two. Whether is a factor *or the sole factor cannot* be said at the ent time.

PERFORATED PEPTIC ULCER AFTER GASTRO-ENTEROSTOMY

IR,—In his article of Oct. 8, Mr. Crowe observes that foration of a peptic ulcer shortly after gastroerostomy appears to be uncommon. The following e is somewhat similar to that described by him.

The patient, a man aged 32, was operated on by Mr. F. R. wn on June 16, 1949, when a wedge resection of a lesservature ulcer was carried out. He made an uneventful overy, and pathological examination of the ulcer confirmed t it was simple in nature. He was readmitted to hospital July 31 with shortness of breath and the story of having a sudden severe upper abdominal pain that day. The n had not eased, and when he was examined typical signs perforated ulcer were found. His abdomen was rigid and ere was a substantial amount of free fluid.

At operation on the same day the presence of free fluid is confirmed, and a small acute perforated ulcer was found st to the pyloric side of the anastomosis where the wedge d been removed. The perforation was closed by a series three stitches of catgut, and the abdomen was closed in ers. His wound healed satisfactorily and he was fit to ave hospital on Aug. 12. His general condition at that time as fairly poor; although he was about 6 ft. tall, his weight as only 9 st. 7 lb. However, when seen again recently, his eight had increased to 12 st., and he looked the very picture f health. He has not been dieted apart from being told to mit all heavy greasy food and spiced dishes, and he has had o complaint of abdominal discomfort.

JOHN GRIEVE.

HEAT CRAMPS

SIR,—I was much interested in the article of Nov. 5 by Dr. Ladell, having myself made some relatively insignificant observations on the same subject[1] when enjoying for that study—so far as environment goes—(to quote Sir Charles Martin) unrivalled opportunities.

Dr. Ladell remarks that heat cramps may occur when water is not drunk to excess or even when it is not drunk at all; this is true. It is also true that almost imperceptible changes in blood-chloride enable the balance in the affected muscle-fibres to be restored, after the administration of salt and water. Another fact is that the miners in Pendleton colliery put small amounts of cream of tartar (potassium bitartrate) in their drinking-water as a cramp preventive.[2] A further curious experience is that of Morton,[3] who administered 1–1$^1/_2$ pints of 2% sodium bicarbonate to his cases, with rapid improvement.

I do not think that cramps are a simple osmotic effect, as Dr. Ladell seems to imply; nor do I consider that muscular exertion is an essential preliminary. A cold environment, I have observed, makes the pain of heat cramps temporarily worse, and cold is a potent cause of muscular cramps even in temperate climes.

One of my patients was very worried in case the heat cramps, which occurred in muscle-fibres situated in parts of the body remote from each other, should spread to his heart. I tried to reassure him by saying that the heart-muscle had never been affected, so far as I knew. The patient remarked: "I might be the first case!"

Epping, Essex.

FRANK MARSH.

CURARE AND PRECIPITATE LABOUR

SIR,—As anæsthetists now use curare for upper-segment cæsarean section and for forceps deliveries, the following case-report may be of interest.

A primipara, aged 25, was admitted to hospital with acute appendicitis on Sept. 22, 1949. She was 38 weeks pregnant. Her temperature was 100·8°F and pulse-rate 130 per min. The abdomen was very tender, with localised guarding in the right iliac fossa. The chest was clear and the urine normal, and she had had no symptoms during her pregnancy.

At 6.20 P.M. she was given 'Omnopon' gr. $^1/_3$ and scopolamine gr. $^1/_{150}$ intravenously. At 6.25 P.M. anæsthesia was induced with a mixture of 10 ml. of thiopentone (5%) and 15 mg. of *d*-tubocurarine chloride (Duncan & Flockhart). Since the patient had had a little food and a drink a short time before, a cuffed tube was inserted. Anæsthesia was maintained with 45% nitrous oxide, 10% cyclopropane, and 45% oxygen. The operation started at 6.35 P.M. An acutely inflamed appendix was removed. Before closing the peritoneum the surgeon was requested to feel the uterus, which he said was as hard as a bullet. The operation was completed at 7.5 P.M. On leaving the theatre the patient was almost conscious; no neostigmine and atropine were necessary, and the fœtal heart was easily audible and beating at 120 per min.

The patient was quite comfortable in the ward until 9.30 P.M. when she requested a bedpan, which she did not use. At 9.45 P.M. she complained of sudden backache, and shortly afterwards labour pains became strong and frequent. At 10.20 P.M. a dead baby girl, weighing approximately 6 lb., was suddenly delivered. No postoperative drugs were given until 11.40 P.M., when the patient received heroin gr. $^1/_{12}$.

Even without curare, operation for appendicitis on pregnant women is said to be followed by abortion or premature labour in 40–80% of cases; and in view of the great increase in uterine tone produced by curare it would seem inadvisable to use it in operations of this type.

3. Morton, T. C. S. *Proc. R. Soc. Med.* 1932, 25, 1263.

that hospital boards should, if it is sought to make them liable for negligent acts of a doctor, take such steps as are open to them under the Law Reform (Married Women and Tortfeasors) Act, 1935, to obtain a contribution from the doctor in respect of damages that may be recovered. (Under the Act such contribution may amount to a complete indemnity.) Whatever may be said for or against this policy, it is evident that common prudence demands in even greater measure than heretofore that medical and other practitioners, whether belonging to the whole-time staff of a hospital or otherwise engaged in the National Health Service, should guard themselves against the risks, both in respect of damages and costs, of actions for negligence. The professional man, whose reputation may be at a stake, cannot safely rely for his defence upon a hospital board, whose interests will conflict with his own. Not only does the State not relieve him of the burden of liability in such cases, but it now seems likely to assume the rôle of an assailant.

This is not the place to discuss whether Lord Justice Denning's extrajudicial observations as reported were intended to refer to all doctors and dentists engaged in the National Health Service, including general practitioners, or whether they are directed only to such doctors and dentists as are employed under a contract of service. It may well be that the narrower interpretation is the correct one; but that is a matter which may hereafter fall to be determined by the courts.

LIVER EXTRACTS, VITAMIN B_{12}, AND THYMIDINE

SIR,—The diminished potency of purified liver extracts prepared during the post-war period from autolysed, so-called pharmaceutical, liver,[1] and other questions concerning vitamin B_{12}, have been repeatedly discussed in your journal. Investigations carried out here may therefore interest your readers.

All substances clinically examined by us have been prepared by Dr. K. Mulli (chemist). Altogether 100 patients with addisonian pernicious anæmia showed an optimal therapeutic response to a series of purified liver extracts, prepared from autolysed pharmaceutical liver by standard methods (Dakin-West, Laland-Klem, and others) and their modifications; and 12 patients reacted in the same way to intramuscular injections of cobalt-containing red pigments (issued in Germany under the name 'Pernipur'); this, we presume, may correspond with the substances described by Lester Smith.[2] The amounts of extracted solid matter and of original liver substance necessary to obtain optimal clinical results sometimes corresponded to pre-war findings,[3] and sometimes exceeded them considerably.[4]

With the methods mentioned above, and particularly precipitation with saturated ammonium-sulphate solution, considerable amounts of active substance will be lost, varying with the degree of autolysis. An active fraction from autolysed liver, not precipitable by saturated ammonium sulphate, soluble in phenol, and free of folic acid and thymine, with regard to the work of Davidson and Girdwood,[5] has been designated by us liver substance III.[6] On further purification this fraction proved to be a concentrate of a cobalt-containing red pigment, which seems to be a lower stage of vitamin B_{12}.[7] From the urine of healthy well as from the urine of patients with pernicious (3 cases), who received intramuscular injections of purified liver extracts, precipitable by sulphate, we were able to obtain concentrates ammonium sulphate which showed a clear action (5 clinical tests). Later on it was demonstra by microchemical analysis that these concentrates contained cobalt, equivalent to their presumable content vitamin B_{12}; but no cobalt-containing substan precipitable by ammonium sulphate, could be detec in these preparations.[7 8]

From sun-dried and air-dried cow-dung,[9] as well from broth-cultures of a strain of *Streptomyces gri* Mulli was *able to obtain—partly by chromatograp* methods—highly purified, cobalt-containing red stances. These concentrates, administered intramu larly in amounts which by microchemical cobalt analy *should be equivalent to about 250–1000 μg. of* vitamin were wholly ineffective in 7 cases of pernicious anæ However, following digestion with hog-stomach mu or with pancreatic-enzyme extract, the cow-dung fa *has shown clear hæmatopoietic activity.*[7]

In the light of these investigations, we assume that least three groups of different forms of vitamin B_{12} exist:

1. Cobalt-containing red compounds, which *on* int muscular injection, even in high doses, are ineffective pernicious anæmia, but with enzymatic cleavage will becom hæmatopoietically active. As precursors of vitamin (pre-vitamin B_{12} or vitamin-B_{12} conjugate, respectiv these are thought to correspond to the extrinsic factor Castle. To this group there probably belong various ot substances with so-called animal-protein-factor activity.
2. Cobalt-containing red pigments, clinically active precipitable by ammonium sulphate, as contained in puri liver extracts and described by Lester Smith.[2]
3. Cobalt-containing red pigments, clinically active soluble in ammonium sulphate, which are present especi in autolysed liver and in urine. These are believed to identical with the Wills factor, liver substance III, and growth-promoting factor of mosquito larvæ.[10]

Under the influence of certain enzymes, which propose to designate as vitamin-B_{12} conjugases and whic are to be found in stomach mucosa, pancreas, kidneys and presumably also in the liver, papain, moulds, an bacteria; the different forms of vitamin B_{12} may becom transformed one into the other and vary in *the liv* according to the degree of autolysis. By microchemica analysis of cobalt, as well as by biological assays of growth in chickens, rats, and moulds, we are not able to differentiate between hæmatopoietically active and inactive forms of the vitamin.

Purified liver extracts were prepared from the livers o two patients with pernicious anæmia who died of intercurrent disease. One patient had addisonian pernicious anæmia, and the other macrocytic anæmia associated with a sprue-like syndrome due to terminal ileitis during severe relapse only intramuscular injections of folic acid had been given. In two clinical trials the purified liver extracts from these sources showed clear therapeutic effect, which was due to their content of vitamin B_{12}.

A highly purified concentrate of thymidine, free of vitamin B_{12} and folic acid, was prepared from purified liver extracts. In one patient with pernicious anæmia where altogether 2 g. was given, after only 1 g. (administered intramuscularly in daily doses of 100–200 mg.) the megaloblastic marrow was restored *to normoblastic* an

e greatest intellects of the world, Plato, Kant, and m philosophers like Whitehead, have shown us Science cannot give us the real picture of the rse, because what we call scientific facts are special s, imposed upon the real "thing in itself" by the ular structure of our intellect. Bergson, Eddington, Karl Jaspers, to quote only a few, have accepted another form of insight, and not the scientific od, is necessary for understanding the spiritual s. We have not the right to judge such spiritual s with the method of the test-tube and of the scope, nor to opine about religious matters without ing deeply the great world thinkers.

e problem of evil is, of course, a great stumbling- , but not only for the religious outlook. To conclude the presence of evil, and thus of disease, that thing is chance, absurdity, blind fate. a great dle, is not more rational than to accept the religious ion, which sees in evil the result of Original Sin, separation of man from God. A world in which tian principles would have a universal application d be a world without evil, because, free from wars, es, and injustices, the human reason would rapidly er physical handicaps. Would not nephritis or emia have been mastered if we had devoted to study the time and money devoted to the dis- ries of an instrument that can wipe out in a few days whole of human life? Evil is a product of man, not od. Everyone of us is responsible. as Dostoievski es, for everything towards everyone.

is the concentration of thought on our internal life, ecial privilege of man, that brings us nearer perennial h. It is by passing behind and beneath the outside of circumstance, beneath our outside self with its tuating moods, and facing the fact of our own indivi- l being that we understand that Science cannot lain human life and that there is another, a trans- lent reality that is the ultimate reality. By viewing essence of being, not in experiments on monkeys or s, not even in general, abstract principles, as in so y philosophies of the Hegelian type, but immediately nan's personal existence we find that man is not a endent creature, the mere product of Nature and iety, but a free spirit transcending itself in its reflection he Supreme Being. To prove things presented to us ernally, such as facts of biology and the principles of c, we have to prove their objectiveness and extrin- lity. Spiritual values, however, can only be appreci- d by the activity of the spirit itself, its intensity and ardour. All this is not Faith, but a well-known thod of philosophical thought which, of course, cannot applied to medical and biological problems, but is only method through which we can approach the blems of God, the Spirit, the Soul.

t here shows that we must impress upon our students nd this is what I endeavoured to do in my active ching days—that Science is to serve Humanity, and t its special method does not allow it to prove or prove religious views. For these, a special insight into e reality of Being, a deep, existential thinking, is cessary with the help of the great philosophers of the st and present.

It is not a coincidence that great physicians of the st were deeply religious: their intellect transcended e test-tube. The scientific humanism which Professor latt describes has given us some honest scientists, but so the atomic bomb. The Renaissance humanism, hich also considered the self-sufficiency of man, has sulted in the gas-chambers of the German Nazis. It a Christian humanism that is needed to save our ivilisation. We cannot, as physicians, adopt the com- ortable attitude of agnosticism or the agreeable behaviour f a juggler playing with the rival points of view of the universe. Such an attitude is allowed to those who have not to live nor act in earnest; but we physicians are living a real life of stress, danger, and responsibility. We have to act, and, thus, we have to choose.

London, W.1. A. P. CAWADIAS.

SIR,—These thoughts come into my mind as I read the admirable letters on this subject in your current issue:

1. Overwhelmed, like Blaise Pascal, whenever I contemplate the Infinite, I fail to see why an Infinite God should be expected to explain either Himself or His doings in full to His finite creatures. Were we in a position to understand fully the problem of cosmic Evil, we should, ourselves, surely be as God.

2. Professor Platt is appalled by the dominance of evil in the world. To me, too, there is far more evidence of a Devil than of God in its management. But was not this Christ's view also? On no less than three occasions He spoke of "the prince of this world" as His and man's adversary. Indeed, throughout His earthly ministry, He recognised a personal spiritual influence presenting evil thoughts to the minds of men which they were free to entertain or not. Was not it His avowed purpose to deliver mankind from the thraldom of the Evil One? The fact that his existence is denied by the greater part of "Christians" of this generation does not disprove it. Did not Baudelaire say that "the Devil's best ruse is to persuade us that he does not exist"?

3. Supposing that Professor Platt's Christless thesis is well founded, it would follow that life is one huge mistake. In such case is not the best never to have been and the second best to die? But, curiously, individual and race suicide to end the misery resulting from disease and man's moral failure does not seem to be a popular programme among agnostics.

4. Whatever be the origin of Evil, there is no doubt that the positive virtues demand it for their development. Is it unreasonable to believe that God overrules Evil for His own good purposes?

5. The end of the business is not yet. Christ offers mankind the prospect not only of a resurrection from the dead—a very different thing from mere survival—but also of His return, not this time in great humility, but in glorious majesty, to rule this tortured world in righteousness. Can Professor Platt offer a more pleasing prospect than that portrayed so vividly by another agnostic, Bertrand Russell, where there is no life beyond the grave, and "all the labours of the ages, all the devotion, all the inspiration, all the noonday brightness of human genius are destined to extinction in the vast death of the solar system"?

6. As regard Professor Platt's creed, for an amusing description of the extraordinary divergence of views of "the least clouded and most elevated" non-Christian minds on such subjects as pleasure, virtue, and pity may I commend to his notice *The Human Situation*, written by the late W. Macneile Dixon from a non-Christian standpoint? That he (Professor Platt) and "the many earnest and beloved physicians who do not subscribe to any orthodox religion" have all been influenced to some extent by an environment which is still, in some measure, Christian, seems certain. That he relies for guidance on conscience is so interesting that one would like to know his opinion as to its origin. That he accepts the Christian ethic and not its author seems somehow illogical.

7. Is it scientific to dismiss a remedy as valueless without trying it out? Christ promises that he who seeks invariably finds. Is Professor Platt in possession of

MOTH-BALL ANÆMIA

SIR,—I was very interested to read your annotation of Oct. 29, since I had under my care in London in 1944 a similar case, which I did not publish.

A boy, aged about 3 years, was admitted to hospital with anæmia. He had been taken suddenly ill two days previously and had become rapidly worse. The day after the onset he began to pass dark urine. On admission he was gravely ill and profoundly anæmic, but he was not icteric. The hæmoglobin was less than 20%, and the red blood corpuscles numbered only a little over 1,000,000 per c.mm. The urine was a port-wine colour owing to hæmoglobinuria. The picture was that of an acute hæmolytic anæmia of Lederer type.

An immediate blood-transfusion was given, followed by a second one two days later. He recovered rapidly without relapse.

The mother volunteered the information that two days before he was taken ill the child had been discovered eating a moth-ball, and she was certain that he had swallowed at least half a one. I had one of the moth balls analysed, and it was found to consist of pure naphthalene. There was little doubt in my mind, therefore, that the acute hæmolytic anæmia was the result of naphthalene poisoning. Although I found statements in one or two textbooks that hæmolytic anæmia could be caused by naphthalene, I could find no report of a similar case.

London, W.1. GEORGE NEWNS.

LACRIMATION

SIR,—In your issue of July 9 Dr. Pickles wrote of involuntary lacrimation accompanying micturition. This has been observed by my son, aged 12, who also remarks that tears come into his eyes when yawning. The amount of tears seems to be about the same with each of these actions.

Wollongong, New South Wales,
Australia. M. C. MCKINNON.

THE DOCTOR'S CREED

SIR,—Professor Platt has opened a new chapter in a very old controversy, but some if not much of the conflict depends on the ambiguity in the terminology used.

The doctor's creed is his own affair and the less he says about it the better. But the doctor's values are totally different. According to his behaviour we can assess his philosophy and in so doing we gain an insight into the efficacy or the inefficacy of his religious teaching and experience.

Many religionists, Christian and otherwise, hold that belief in a particular scheme of dogmas is by itself adequate for the good life. Now we all know exceptions to this rule—men and women who claim 100% belief in the Bible or the Koran, but whose conduct in life does not express Christ's or Mahomet's philosophy. On the other hand, there are those—very few perhaps—who are unable to believe, and yet have acquired Christ's philosophy. In short, belief is not an adequate basis for philosophy. But the real trouble is the use of the word "belief" when the manifest content of a story covers a latent symbolic content of paramount and permanent value. If we take the story of Jonah in the whale's belly, the word "belief" is inappropriate; no intelligent adolescent takes it literally. Yet what proportion of adults are there who have learned the story in childhood and succeed in adult life to apprehend the latent message of rebirth contained in that story? Or how many of these adults have correlated it with the question Nicodemus put to Jesus? Or again, many young people have been taught Greek mythology and among other priceless myths have got to know the story of the Sowing of the Dragon's Teeth? No teachers have asked them to "believe" this story; yet the apprehension of its symbolical significance has a great contribution to to the philosophy of the adult. In short, religious and religious experience are imperfect if they do lead to maturity and a progressive scale of values. to the conflict between Science and Religion, I maint that Science has nothing to fear from Religion, as Religion has nothing to fear from Science. Science dea with the objectively demonstrable and is constant advancing its frontiers.

The religionists (and here it is the East which is mo at fault than the West) put forward certain guesses und the heading of dogma. They are all entitled to th guesses. Indeed the human mind is so constituted tha cannot endure the Unknown and the Unknowab without attempting to develop fantasies which a largely based on wish-fulfilment. They and we are free to entertain such fantasies. The young, the primitiv and the mentally inferior all demand personificati and objectivication in the Unknown. They and we free to believe what we like of such dogmas but to imp such "belief" is inadmissible. In other words, a may attain to Christ's philosophy by training experience; but the creed he holds may and does va not only from that of his neighbour, but also from th of his own childhood.

Harrow-on-the-Hill. H. CRICHTON-MILLER.

SIR,—Prof. Robert Platt's letter, arising out of t Archbishop of Canterbury's speech at Birmingha demonstrates again how strangely illogical we medic men can be when it comes to questions of philosophy a theology.

Having stated that he rejects the Christian creed, h attempts to justify the ethic which arises naturally fro that creed—on the flimsiest and most personal ground Why *should* our conduct be determined by "a sense personal responsibility," or by the inner satisfaction doing right? To whom are we to be personally respo sible, and why? How are we to know what is right a what is wrong? The undermining of religious belief, a the materialistic outlook which has evolved since th Reformation, has resulted in the product of such strange person as Professor Platt, who is conditioned behave as a Christian, although he cannot give a adequate reason why he does so.

In respect of Professor Platt's inability to accept th Christian creed, owing to his difficulty in imagining a omnipotent, benevolent, and merciful God who can ye tolerate evil, the rather infantile answers which h presumes will be forthcoming would not be given by an theologian.

The greatest gift that God could give to man surel was that of freedom of choice. That man chooses evil i unfortunate; but he frequently chooses what is good and, being an optimist, I see that the good in mankin on the whole greatly outweighs the evil. To create i creature devoid of this freedom of choice would have be to relegate us to the sphere of mere automata who coul neither have had "a sense of personal responsibility nor given greater glory to God. Péguy epitomised thi rather nicely when he said, "God, having once experi enced the love of free men, has no use for the obeisanc of slaves."

We should be grateful to the Archbishop of Canterbur for his clarion call to members of the medical professio to consider again the nature of man and his purpose.

T. CECIL GRAY.

Liverpool.

SIR,—Professor Platt shows in his letter a grea scientific sincerity and humanity. He makes, however the fundamental mistake of applying the scientifi method and reasoning to the transcendental question o religion, and of considering that the only alternativ is faith.

body. Three statements of Jesus are illuminating: not fear those who kill the body but cannot kill soul: rather fear Him Who can kill both body and in hell"; "He who loves his life loses it, and he hates his life in this world will keep it for eternal ': "the flesh profits nothing." Thus that which reasure so dearly—namely, life of the body—is, in sight of God, and therefore in reality, as nothing ared with that truly precious life of the spirit. ugh none of us expects the body to live for ever, nake the mistake of setting far too high a value it when faced with the possibility or fact of a.

t the subject of such sufferings as those endured e concentration camps the Word of God is equally inating and equally startling. The Old Testament the story of that nation which was given the job owing the other nations of the world what a wonder-hing life could be if lived in obedience to God. escribes the ghastly failure of that nation in God's ose owing to wilful, deliberate wickedness. Could d of Love allow free course to the sin which could g about nothing but the utter ruin not only of those indulged in it, but also of those who beheld and wed their example? No. He must needs punish e whom He loved, for punishment is intended arily to restore. But there were those who resisted y effort to restore, who remained a contaminating ce of infection to others, and thus we find that the t frightful wickedness calls forth the most frightful ishment—given only after clear and oft-repeated nings. Indeed the very things which Professor Platt rds as proof of the non-existence of God are those h, according to the Bible, God has used as ishments for man's wickedness.

he Old Testament is remarkably up to date and ws a clear light on the puzzling happenings of the years; but I regret that Churchmen do much to ttle its value, ascribing those portions which are ctionable to modern ears to the "ignorance" and imitiveness" of the human writers.

laînth, Dorset. P. R. BOUCHER.

R.,—The objection raised by Professor Platt to Fisher's affirmation is indeed not new. It is a serious , and could have been stated even more strongly. ect answers to it seem always to beg further questions those who are not Christians. To those who are, matter does not appear quite the same; and to gest, as might be done, that they either ignore evil blindly accept orthodoxy is to deny the reality of a at deal of Christian thought and action. May I ke two comments?

f a man demands that this objection be answered ore he can or will believe in the God the Christians rship, then in all humility I would say that I do think God can or will provide an answer to a free ature of His in such a prosecuting or judicial frame mind.

Second, I understand that in philosophy it has been t unfruitful when a question yields perplexing answers reconsider the question. I would respectfully suggest Professor Platt that he think over again the meanings intends by "omnipotent" and "wholly benevolent," d compare these meanings with those arrived at by hristian theologians of an intellectual stature equal to s own.

Helston, Cornwall. GEORGE JOHNSON.

SIR,—One of the best-known books written by H. G. ells is "The Story of a Simple Soul." I always feel, owever, that there is a simpler soul even than this, nd it is the person in the surgery who sometimes says: Why does my mother (or father, or whoever it may be) have to suffer from this terrible disease? She has never done any harm to anyone." That anyone of Dr. Platt's medical eminence should put out this self-same query more or less rather takes one's breath away. We know little still of the origin of many of the diseases which we have to treat; but we know that some are inherited; and what (so far as our present knowledge goes) is to prevent leukæmia and acute nephritis—to mention the two diseases referred to by Dr. Platt—being possibly inherited too? The influence of the misspent life (not necessarily sinful) of some distant ancestor may be carried down in the chromosomes of the victim of acute leukæmia, and we are merely having a repetition of the Biblical reminder that the sins of the fathers shall be visited upon the children unto the third and fourth generations.

The question of free will has been brought out by more than one of your correspondents. Man, who is clever enough to invent radar and television, should surely be intelligent enough to protect himself from man's inhumanity to man. Why should the Deity be expected always to lead him by the hand when he is so infernally clever himself? So many today think they have "grown out" of religion. The essence of Christianity is still simplicity and humility, but man—"that miserable two-forked radish" as Carlyle called him—is now too big for his boots. In spite of his apparent cleverness he remains at the mercy of his dictators and has to suffer all the horrors which they bring upon him. His sufferings should remind him of his own impotence; but they have not yet succeeded in doing so.

Brighton. G. L. DAVIES.

SIR,—Professor Platt has done us a good service in voicing the thoughts, rarely heard in public, of many doctors and of an increasing number of the rising generation. We easily forget the significance of the fact that our beliefs are largely determined by the circumstances of our upbringing. Those of us brought up in the Christian faith rarely question the teaching and the feeling that our religious experience results from our personal contact with the Creator. To many not so brought up, and their number is rapidly increasing, this idea appears to be without foundation. While having a great respect for the Archbishop of Canterbury and valuing his guidance on ethical matters they will be little influenced by his answers to the "three problems or mysteries."

The one thing that is common to the many sects of Christians is the fervent desire that Christ's way of life shall prevail. Now among people of Professor Platt's persuasion are many who wish for just the same end and who do not simply enjoy the benefits of the Christian spirit handed down to them but allow increase to that spirit in their lives and hand on that spirit to their children.

Those of us who are concerned, or would be concerned, with the future welfare of mankind will do well to remind ourselves of these facts constantly. We will do well to relegate our beliefs to a subordinate place and have faith in the Spirit of Christ that is abroad. Let those who stand outside the Church not throw stones at the windows but enter in and open them. Let those who are within the Church not pray for the unbelievers outside but open the doors and remove the stumbling-blocks to all those who sincerely desire to seek Christ's way of life.

Recent correspondence in the *Times* has shown again how apparently insuperable are the obstacles to unity within Christendom. Is it not time that there was another revolution within the Church? The alternative would seem to be a further loss of way and drift toward the rocks.

Bristol. HARRY F. WEST.

any evidence that this promise is vain? Pascal, one of the world's greatest scientists, declared that he, at any rate, could discover none.

London, W.1. J. W. LINNELL.

SIR,—The first step towards a clearer understanding of experience, both in religion and in science, has been taken when a distinction has been made between things that are both similar, and also significantly different. To call both "Buchenwald" and the death of an innocent "child from leukæmia," evil is to fail to recognise a significant difference. Most will agree that Buchenwald was predominantly man-made and that (so far as we know) leukæmia is predominantly due to natural causes. In this letter I shall use the word "evil" to describe "Buchenwald-like" conditions and consequences, and I shall use the word "bad," to describe the "bad" results produced by natural conditions. It might prove to be true to hold that God is in no sense "responsible" for evil, and yet was (in some sense) responsible for "bad"; and to do so without contradicting the basic religious insight that "God is Good." For my part I consider that modern Christian philosophers have succeeded in offering such an "explanation of evil" and that that explanation is rational, scientifically credible, and religiously satisfying.

Since, however, I am certain that neither religion nor science can make any satisfactory progress towards an understanding of the "problem of evil," until that problem has been restated in this dual form, I wish to draw attention to this significant difference. We are discussing two different problems, that require different explanation and are amenable to different methods of "cure." May I add also, that the good and the healthy call for just as much "explanation," as do the "bad" and the "evil."

Worcester. H. E. COLLIER.

SIR,—It has often been stated that it is impossible to accept the ethic of Christianity without accepting the doctrine. I believe this to be true, for the two are inseparable. He Who said, "Blessed are the peacemakers" also said, "Blessed are ye, when men shall revile you, and persecute you, and say all manner of evil against you falsely, for my sake." Without the acknowledgment of a Being higher than oneself, to Whom one is responsible moment by moment, practice of the Ethic is subject to qualification by the Ego which it is the Agnostic's goal to satisfy. A version of the Ethic, edited by a political conscience, may well serve to rally the masses for atomic warfare, but will it produce a Niemoller?

As for Professor Platt's "better hypothesis," provide me with a laboratory in a camp of starving men, and only let enough friends advise me that the end justifies the means, and I shall achieve the inner satisfaction of doing right by experimenting on, and expediting the end of, hundreds of people already doomed—and that in the cause of scientific truth. Regiment me with the rough, and teach me to admire my superiors, and how long will my conscience gainsay the impression that the gift of self-assertion and the grace of undetectability are the endowments most to be coveted? Replenish me with respect for truth and present me with the dilemma that a lie told just for once will ultimately further the cause of truth, and to what court shall my conscience take the conflicting claims of Propaganda and Information? Did ever a murderer fail to justify himself, to himself?

It is only my belief in a higher Judiciary that will keep the bench of my conscience alert to the "Thou shalt not" of the Bible, as against the special pleading of my own inclinations, always biased in favour of my own immediate interest as I see it in terms of a relatively short duration.

London, N.19. S. R.

SIR,—There are many thinking persons on the f of religion, and I believe that Dr. Platt's feelings those, not only of many earnest doctors, but of majority of medical men today. It is probably b to be an honest atheist or agnostic than simply believe because one has been brought up to bel The important thing is to try to think these things for ourselves, and here the Archbishop's address is helpful because it gives us something to bite on. E so, faith is a very difficult thing to acquire and it is a at the level of simplicity and humility that we obtain it.

The explanation of the presence of evil in the wo in spite of an omniscient, omnipotent, and wholly be volent God, has already been given by some of correspondents. It is a sequel to the endowme man with a will of his own to choose good or evil. made the world to be ruled by certain physical which for practical purposes never change; so we have a purely materialistic outlook if we wish. will not be proved scientifically, mathematically, b miracle, or in any other way unless faith is alre present. He is obvious enough in the works of na and yet remains almost incredible. Man, it seems, evolved with a mind just capable of comprehend the existence of an Almighty God, but the balance realisation is very finely adjusted. The initial appro must be made by the individual concerned and it not depend on mental development or reasoning pow in fact the simple-minded often find it easier to acq faith. The earth is the testing-ground; man's will m therefore be allowed to prevail on it.

The knowledge of the sum total of good and evi the world at any one time could explain many of world's evils. The atrocities of Buchenwald and Au witz are the indirect result of the intensity of evil, hatred, the greed for power, and the unscrupul domination of the Hitler régime: in other words, th were due to the development of evil in man and by m The child dying of leukæmia is, I admit, more diffic to explain, but the difficulty is not now one of explanation of the presence of evil, but of its distribut This distribution may remain incomprehensible to the without faith and is, I agree, a great barrier to t acceptance of Christianity; but to those who ha faith in Christ there is no difficulty at all. We have alrea been reminded by Dr. Carroll that the symbol Christianity is a Cross.

Having tried to explain the presence of evil a having discussed its distribution, it behoves us consider how to overcome it, and here again the answ is found in the teachings of Christ, "return good f evil."

Norwich. G. K. MCKE

SIR,—All Christian apologists appear to accept hum sorrow and suffering as a sign of a consequence of ma "having fallen from God." Would any of them ca to consider the case of a rabbit being eaten slowly by a weasel?

Buxton.

SIR,—I am sure that the important difficulty described by Professor Platt occurs only in the minds of those thinkers who have not seen the whole of the picture. The whole truth is to be obtained only from the study of the entire Bible, Old Testament and New.

The first thing to be understood is the true value of what is usually called "life," and refers to the life of ody. Three statements of Jesus are illuminating: not fear those who kill the body but cannot kill oul: rather fear Him Who can kill both body and in hell"; "He who loves his life loses it, and he hates his life in this world will keep it for eternal ; "the flesh profits nothing." Thus that which reasure so dearly—namely, life of the body—is, in ight of God, and therefore in reality, as nothing ared with that truly precious life of the spirit. ugh none of us expects the body to live for ever, ake the mistake of setting far too high a value it when faced with the possibility or fact of h.

the subject of such sufferings as those endured e concentration camps the Word of God is equally inating and equally startling. The Old Testament the story of that nation which was given the job owing the other nations of the world what a wonder- hing life could be if lived in obedience to God. scribes the ghastly failure of that nation in God's ose owing to wilful, deliberate wickedness. Could d of Love allow free course to the sin which could about nothing but the utter ruin not only of those indulged in it, but also of those who beheld and wed their example? No. He must needs punish e whom He loved, for punishment is intended arily to restore. But there were those who resisted y effort to restore, who remained a contaminating ce of infection to others, and thus we find that the frightful wickedness calls forth the most frightful shment—given only after clear and oft-repeated ings. Indeed the very things which Professor Platt rds as proof of the non-existence of God are those h, according to the Bible, God has used as shments for man's wickedness.

he Old Testament is remarkably up to date and ws a clear light on the puzzling happenings of the years; but I regret that Churchmen do much to tle its value, ascribing those portions which are ctionable to modern ears to the "ignorance" and imitiveness" of the human writers.

nfrith, Dorset. P. R. BOUCHER.

IR,—The objection raised by Professor Platt to Fisher's affirmation is indeed not new. It is a serious and could have been stated even more strongly. ect answers to it seem always to beg further questions those who are not Christians. To those who are, matter does not appear quite the same; and to gest, as might be done, that they either ignore evil blindly accept orthodoxy is to deny the reality of a at deal of Christian thought and action. May I ke two comments?

I a man demands that this objection be answered ore he can or will believe in the God the Christians ship, then in all humility I would say that I do think God can or will provide an answer to a free ture of His in such a prosecuting or judicial frame ind.

econd, I understand that in philosophy it has been unfruitful when a question yields perplexing answers reconsider the question. I would respectfully suggest Professor Platt that he think over again the meanings intends by "omnipotent" and "wholly benevolent," d compare these meanings with those arrived at by ristian theologians of an intellectual stature equal to own.

elston, Cornwall. GEORGE JOHNSON.

SIR,—One of the best-known books written by H. G. ells is "The Story of a Simple Soul." I always feel, wever, that there is a simpler soul even than this, d it is the person in the surgery who sometimes says: Why does my mother (or father, or whoever it may be) have to suffer from this terrible disease? She has never done any harm to anyone." That anyone of Dr. Platt's medical eminence should put out this self-same query more or less rather takes one's breath away. We know little still of the origin of many of the diseases which we have to treat; but we know that some are inherited; and what (so far as our present knowledge goes) is to prevent leukæmia and acute nephritis—to mention the two diseases referred to by Dr. Platt—being possibly inherited too? The influence of the misspent life (not necessarily sinful) of some distant ancestor may be carried down in the chromosomes of the victim of acute leukæmia, and we are merely having a repetition of the Biblical reminder that the sins of the fathers shall be visited upon the children unto the third and fourth generations.

The question of free will has been brought out by more than one of your correspondents. Man, who is clever enough to invent radar and television, should surely be intelligent enough to protect himself from man's inhumanity to man. Why should the Deity be expected always to lead him by the hand when he is so infernally clever himself? So many today think they have "*grown out*" of *religion*. The essence of Christianity is still simplicity and humility, but man—"that miserable two-forked radish" as Carlyle called him—is now too big for his boots. In spite of his apparent cleverness he remains at the mercy of his dictators and has to suffer all the horrors which they bring upon him. His sufferings should remind him of his own impotence; but they have not yet succeeded in doing so.

Brighton. G. L. DAVIES.

SIR,—Professor Platt has done us a good service in voicing the thoughts, rarely heard in public, of many doctors and of an increasing number of the rising generation. We easily forget the significance of the fact that our beliefs are largely determined by the circumstances of our upbringing. Those of us brought up in the Christian faith rarely question the teaching and the feeling that our religious experience results from our personal contact with the Creator. To many not so brought up, and their number is rapidly increasing, this idea appears to be without foundation. While having a great respect for the Archbishop of Canterbury and valuing his guidance on ethical matters they will be little influenced by his answers to the "three problems or mysteries."

The one thing that is common to the many sects of Christians is the fervent desire that Christ's way of life shall prevail. Now among people of Professor Platt's persuasion are many who wish for just the same end and who do not simply enjoy the benefits of the Christian spirit handed down to them but allow increase to that spirit in their lives and hand on that spirit to their *children*.

Those of us who are concerned, or would be concerned, with the future welfare of mankind will do well to remind ourselves of these facts constantly. We will do well to relegate our beliefs to a subordinate place and have faith in the Spirit of Christ that is abroad. Let those who stand outside the Church not throw stones at the windows but enter in and open them. Let those who are within the Church not pray for the unbelievers outside but open the doors and remove the stumbling-blocks to all those who sincerely desire to seek Christ's way of life.

Recent correspondence in the *Times* has shown again how apparently insuperable are the obstacles to unity within Christendom. Is it not time that there was another revolution within the Church? The alternative would seem to be a further loss of way and drift toward the rocks.

Bristol. HARRY F. WEST.

any evidence that this promise is vain? Pascal, one of the world's greatest scientists, declared that he, at any rate, could discover none.

London, W.1. J. W. LINNELL.

SIR,—The first step *towards* a clearer understanding of experience, both in religion and in science, has been *taken when* a distinction has been made between things *that* are both similar, and also significantly different. To call both "Buchenwald" and the death of an *innocent "child from leukæmia,"* evil *is to fail to* recognise a significant difference. Most will agree *that* Buchenwald was predominantly man-made and that (so *far* as *we know*) leukæmia is *predominantly* due to *natural* causes. In this letter I shall use the word "evil" *to* describe "Buchenwald-like" conditions and consequences, and I shall use the word "bad," to describe the "bad" results produced by natural conditions. It might *prove to be* true to hold that God is in *no sense* "responsible" for evil, and yet was (*in some sense*) responsible for "bad"; and to do so *without* contradicting the basic religious insight that "God is Good." For my part I consider that modern Christian philosophers have succeeded in offering such an "explanation of evil" *and that that* explanation is rational, scientifically credible, and religiously satisfying.

Since, however, I am certain that neither religion nor science can make any satisfactory progress towards an understanding of the "problem of evil," until that *problem has been restated in this dual form, I wish to* draw attention to this significant difference. We are *discussing* two different problems, that require different explanation and are amenable to different methods of "cure." May I add also, that the good and the healthy call for just as much "explanation," as do the "bad" and the "evil."

Worcester. H. E. COLLIER.

SIR,—It has *often* been stated that it is impossible to accept the ethic of Christianity without accepting the *doctrine. I* believe *this* to be true, for the two are *inseparable.* He Who said, "Blessed are the peacemakers" also said, "Blessed are ye, when men shall *revile you, and persecute you,* and *say all manner* of evil against you falsely, for my sake." Without the acknowledgment of a Being higher than oneself, to Whom *one* is *responsible* moment by moment, practice of the Ethic is subject to qualification by the Ego which *it is* the Agnostic's goal to satisfy. A version of the Ethic, edited by a political conscience, may well serve *to rally the masses for atomic warfare, but* will it produce a Niemoller?

As for Professor Platt's "better hypothesis," provide me with a laboratory in a camp of starving men, and only let enough friends advise me that the end justifies the means, and I shall achieve the inner satisfaction of doing right by experimenting on, and expediting the end of, hundreds of people *already doomed*—and that in the cause of scientific truth. Regiment me with the rough, and teach me to admire my superiors, and how long will my conscience gainsay the impression that the gift of self-assertion and the grace of undetectability are the endowments most to be coveted? Replenish me with respect for truth and present me with the dilemma that a lie *told just for* once will ultimately further the cause of truth, and to what court shall my conscience take the conflicting claims of Propaganda and Information? Did ever a murderer fail to justify himself, to himself?

It is only my belief in a higher Judiciary that will keep the bench of my conscience alert to the "Thou shalt not" of the Bible, as against the special pleading of my own inclinations, always biased in favour of my own *immediate interest* as I see it in terms of a *relatively short duration.*

London, N.19. S. R.

SIR,—There are many thinking persons on the of religion, and I believe that Dr. Platt's feeling those, not only of many earnest doctors, but of majority of medical men today. It is probably to be an honest atheist or agnostic than simp believe because one has been *brought up to be* The important thing is to try to think these things for ourselves, and here the Archbishop's address is helpful because it gives us something to bite on. so, faith is a very difficult thing to acquire and it is at the level of simplicity and humility that we obtain it.

The explanation of the presence of evil in the w *in spite of an* omniscient, omnipotent, and wholly volent God, has already been given by some of correspondents. It is a sequel to the endowme man with a will of his own to choose good or evil. made the world *to* be ruled by certain physical which for practical purposes never change; so we have a purely materialistic outlook if we wish. will not be proved scientifically, mathematically, miracle, or in any other way unless faith is alre *present.* He is *obvious* enough in the works of na and yet remains almost incredible. Man, it seems, evolved with a mind just capable of comprehend the existence of an Almighty God, but the balanc realisation is very finely adjusted. The initial appro must be made by the individual concerned and it not depend on mental development or reasoning po in fact the simple-minded often find it easier to acq faith. The earth is the testing-ground; man's will therefore be allowed to *prevail on it.*

The knowledge of the sum total of good and evi *the* world at any *one time* could explain many of world's evils. The atrocities of Buchenwald and Au witz are the indirect result of the intensity of evil, hatred, the greed for *power, and* the unscrupu domination of the Hitler régime: in other words, were due to the development of evil in man and by m The child dying of leukæmia is, I admit, more diffi to explain, but the difficulty is not now *one of* explanation of the *presence* of evil, but of its distribu This distribution may remain incomprehensible *to th* without faith and is, I agree, a great barrier to acceptance of Christianity; but to those who h faith in Christ there is no difficulty at all. We have alre been reminded by Dr. Carroll that the symbol Christianity is a Cross.

Having tried to explain the presence of evil a having *discussed its* distribution, it behoves us consider how to overcome it, and here again the ans is found in the teachings of Christ, "return good evil."

G. K. McKE

Norwich.

SIR,—All Christian apologists appear to accept huma sorrow and suffering as a sign of a consequence of ma "having *fallen from God.*" Would any of them ca to consider the *case* of a rabbit being eaten slowly b a weasel?

OINS.

Buxton.

SIR,—I am sure that the important difficulty describ by Professor Platt occurs only in the minds of tho *thinkers who* have *not* seen the whole of the pictu The whole truth is to be obtained only from *the stu of the entire* Bible, Old Testament and New.

The first thing to be understood is the true va of what is usually called "life," and refers *to the life* who had been unvaccinated at the time of contact, put under observation with symptoms of early pox. His illness is relatively mild.

original case may possibly have infected others g the pre-eruptive stage, but all contacts are believed under close surveillance and spread to the general is not expected.

Poliomyelitis

ring the week ended Nov. 5, notifications in England Vales were: poliomyelitis 318 (347), polioencepha- .2 (20). Figures for the previous week are shown rentheses. Prevalence is falling slowly but remains pread as is shown in the following list of counties which multiple cases were reported :

don 50 (55), Bedford 6 (2), Berks 7 (3), Buckingham Chester 16 (10), Derby 3 (2), Devon 3 (3), Dorset 7 (3), m 3 (2), Essex 24 (26), Gloucester 6 (9), Hereford 4 (2), ord 4 (9), Huntingdon 5 (0), Kent 15 (16), Lancaster), Leicester 12 (3), Lincs, Lindsey 5 (13), Middlesex), Norfolk 7 (5), Northampton 4 (1), Northumberland Nottingham 9 (8), Oxford 2 (2), Salop 2 (0), Somerset , Southampton 9 (13), Stafford 7 (3), Suffolk, East 2 (2), 6 (14), Sussex, East 5 (9), Warwick 7 (8), Westmorland Wiltshire 2 (1), Yorks, North Riding 2 (2), Yorks, West), Glamorgan 4 (7).

Water-pollution Research

e Department of Scientific and Industrial Research ssued, albeit somewhat tardily, the report of the r Pollution Research Board for 1948.[1] If this work s at present more closely concerned with helping stry and public undertakings than with promoting c health, it is reassuring to find that manufacturers statutory bodies are coöperating in the fight against ition.

ere is an interesting account of the re-use of sea r for cleaning shellfish—a matter of importance e mussels or other shellfish from tainted areas cleansing in water which at neap tides is deficient linity. Sea water re-oxygenated after a prescribed ment with sodium hyperchlorite and after aeration apparently be used again and again for this purpose ghout a whole season.

other object of the board's research was the nuisance ed by flies emerging from the percolating filters h treat settled sewage. Successive applications of ticide (D.D.T. and 'Gammexane'), adjusted to the population and to weather conditions, gave good lts at low cost. The quantity, however, must be fully controlled. Too much gammexane causes nding" of the filter and may diminish its efficiency. eover, gammexane, like other insecticides, is strongly c to fish if applied in excessive doses. One of the es included in the report gives details of the average city to rainbow trout of gammexane in different entrations and at different temperatures.

he board has been studying various industrial waste ers—those, for instance, resulting from the processing isal and coffee in Kenya, the washing of wheat, the ping of barley, the brewing of cider, and the "pick-" of steel. Another task was an investigation of the sey estuary to determine the effect of the discharge rude sewage on the composition and properties of mud in the navigable channels and in the big tidal n between Liverpool and Widnes. Most of the terial dredged up out of the upper estuary seemed to e been brought in from the sea rather than from the sh-water streams. The discharge of crude sewage o the estuary had no marked effect on the rate of imentation of the flocculated mud carried to and fro the tide. Lately a similar inquiry has been underken, at the request of the Mersey Docks and Harbour ard, to find the effect of discharging into the head of e estuary an alkaline sludge resulting from the manuture of sodium carbonate by the Solvay ammonia ocess at the Cheshire works of Imperial Chemical dustries. The manufacturers provided laboratory cilities and lent some of their chemists. Useful information has been obtained of the rate of deposit of Mersey ud and of its resistance to erosion, though it is too early to make any confident forecast of the ultimate effects. The department is now embarking upon a three-year examination of the causes of silting in the Thames estuary. The Port of London Authority is providing a laboratory at Tilbury and a specially fitted launch for surveys. Experiments will be made with a large-scale model of the river from Teddington to the Nore.

In enacting the River Boards Act last year, Parliament gave the big new boards the responsibility for preventing river pollution and the power to obtain information from any persons who appear to be discharging effluents into streams or inland waters. The Thames, with its special problems and authorities, was excepted from the Act. Let us hope that our legislators will somehow some day see it a salmon river again.

Obituary

SIR HERBERT EASON

A FRIEND writes: If History knows her business she will put Herbert Eason, along with Brodie, Henry Acland, and MacAlister, in the first class among the eleven presidents of the General Medical Council. Called to the chair after 15 years of service, he filled it with ever-growing acceptance by his colleagues through almost 10 years of unprecedented strain.

There are paradoxes in every interesting character, and in Eason's there were many. As a man he looked back to the past; as a president he looked, and encouraged his council to look, to the future. He did not seem to think mankind had improved since about 1750; and this outlook combined with a profound personal reticence to make it easier for him to show affection for institutions than for men. He did not abound in reverence: but he revered Guy's, the Law, and the General Medical Council.

In the chair he displayed unerring power to refer instantaneously to relevant provisions of the Medical Acts and of the standing orders; unhesitating ability to guide rather than to rule the course of business; the lawyer's aptitude for putting to a shifty witness the one deadly question; urbanity in encouraging and bringing forward junior colleagues; patience (not practised without strain) in listening to speakers who had not his gift of terseness; and control of his own command of pungent phrases throughout the public proceedings. The smooth running of every meeting over which he presided was ensured, so far as might be, by detailed rehearsal and prediction of the course of events.

In medical education, which he realised with keen historical sense to be the primary business of the council, it was his policy to leave to universities and medical corporations the freedom, guaranteed to them in 1858, to teach and examine as they would, if only they taught and examined up to a standard sufficient to make the public safe. He set his face against any attempt to undermine or circumvent that freedom by subterfuge or subtlety in drafting. It is true that he did not think the prolonged and difficult labour of the council in producing new recommendations about the minimum curriculum was best conducted in the public hearing. But he gave support, expressed with unaccustomed warmth, to the policy of enlightening anybody who might feel concerned, which the council first fully adopted in explaining their *Rules* (1945) *for Diplomas in Public Health,* and their revised *Recommendations* (1947) *as to the Medical Curriculum*, both issued during his presidency. In 1946, in search of the best that was to be had for assimilation into the new recommendations, he led a delegation of four of his younger colleagues on the council to visit medical schools in America and Canada, under the auspices of the Rockefeller Foundation —an experience he thoroughly enjoyed except for recurrent anxieties about missing trains; he was devoted to punctuality.

As spokesman of the council in exercise of discipline he sighed as a man—an autobiographical fragment reveals that he hated ordering the erasure of a name— but obeyed as an intellect. Indeed he may have given the impression, as he brilliantly maintained the right of the council to find whatever was discoverable of truth,

Parliament

New Clauses to Amending Bill

Lord **SHEPHERD**, on behalf of the Government, has tabled the following new clauses for insertion in the National Health Service (Amendment) Bill. The committee-stage of the Bill is being taken in the House of Lords this week.

Regulations made under section 34 of the Act of 1946 and regulations made under section 35 of the Act of 1947 may confer or impose on the Medical Practices Committee or, as the case may be, the Scottish Medical Practices Committee such additional functions in relation to arrangements for the provision of general medical services as may be prescribed.

Section 38 of the Act of 1946 and section 40 of the Act of 1947 (which provide for the making of arrangements for pharmaceutical services) shall be amended by the addition at the end of each of those sections of the following subsection:

> (3) Regulations may provide for the making and recovery, in such manner as may be prescribed, of such charges, in respect of such pharmaceutical services, as may be prescribed, and the regulations may provide for the remission or repayment of the charges in the case of such persons as may be prescribed.

The powers of the Minister to make regulations under the Act of 1946 shall, notwithstanding anything in section 1 of that Act, include power to make regulations providing for the making and recovery, in such manner as may be prescribed, of such charges, in respect of such services provided under the Act of 1946, as may be prescribed, being services provided in respect of such persons not ordinarily resident in Great Britain as may be prescribed; and such regulations may provide that the charges are only to be made in such cases as may be determined in accordance with the regulations.

QUESTION TIME

War Pensioners and Medical Prescriptions

Replying to questions asking what method would be adopted to ensure that war pensioners who were receiving treatment for pensionable disability would be exempt from the charge which was to be made for medical prescriptions, Mr. H. A. **MARQUAND** said: The pensions instruments ensure free treatment—including medicines and dressings—for war pensioners for their pensioned disabilities. Disabled men have never during the last 30 years failed to receive the free treatment and they will not fail now. I shall continue to discharge this obligation. Detailed arrangements will be announced when a change has been made in the existing provisions of the National Health Service.

Treatment of Arthritis

Colonel J. R. H. **HUTCHISON** asked the Minister of Health what steps he was taking to encourage the production of the anti-arthritis discovery, 'Cortisone.'—Mr. A. **BEVAN** replied: The Medical Research Council, in touch with the Nuffield Foundation, is promoting intensive research into cortisone and other substances that might take its place and be available in adequate amounts. Various pharmaceutical firms, with whom my officers are in close contact, are also actively engaged in this field. I am prepared to render all the assistance in my power. Colonel **HUTCHISON**: While it is not desirable to raise public hopes too high in this connexion, is the Minister satisfied that there should not be any access to, or liaison with, the Mayo Clinic in America where I believe the discovery was made?

Mr. **BEVAN**: I think the hon. Member can take it for granted that all the scientific information that can be made available is made available in this field, but what we are looking for is a material out of which this substance can be cheaply and plentifully made.

Dentists and the N.H.S.

Colonel M. **STODDART-SCOTT** asked the Minister how many dentists had withdrawn from the National Health Service during the present year; how many were still withholding their service; and which townships in England and Wales had no dental treatment facilities for N.H.S. patients.—Mr. **BEVAN** replied: There were 9468 dentists on the dental lists of executive councils on Oct. 1, compared with 8914 on Jan. 1—a net increase of 554; it is believed that about 500 general dental practitioners have not joined the service; the names and addresses of dentists taking part are shown in lists available at post offices, but to get out the information in the form suggested would involve considerable tim labour, which I do not think would be justified.

Supply of Wigs

Mr. **MARQUAND**, Minister of Pensions, informed Sir E. GRA -**LITTLE** that about 7700 wigs had been provided unde National Health Service. There was no information whether any of these were supplied to foreign visitors. firms had been invited to tender for the supply of wigs. average price was considerably less than £18.

Cost of Hearing-aids

Mr. F. J. **ERROLL** asked the Minister of Health in proportions and amounts the cost of the 'Medresco' he aid, recently officially announced to [illegible] any costs of research, development. [illegible] tion, fitting, and servicing.—Mr. B [illegible] represents approximately the manufacturing cost o original aid but does not include all the costs referred the hon. Member.

Eradication of Tuberculosis in Cattle

Replying to a question Mr. **TOM WILLIAMS**, Minis Agriculture, stated that the proposed scheme for the eradi of tuberculosis in cattle on an area basis would be intro on Oct. 1, 1950.

Public Health

Typhoid at Salford

ON the morning of Monday, Nov. 7, the m officers of health of Salford learned that 3 patie surrounding townships were thought to be suffering typhoid fever. During the day the number of increased till at 4 P.M. there were 7. All these pa had eaten a meal at the Masonic Hall, Salford, on (This meal consisted of reconstituted dried celery roast beef, mashed and baked potatoes, carrots, cabbage; trifle; and coffee.

The water-supply could be reasonably excluded primary consideration because fortnightly tests i preceding months had shown no coliform orga present and a residual chlorine of 0·1 parts per 1,00 The milk-supply could similarly be excluded as i known that the dairy gave efficient heat trea and that the staff were careful operators. No sh or foodstuffs such as watercress had been consumed

Suspicion fell on the trifle, but it was found 2 of the patients with typhoid had not eaten an was soon apparent that there was no consistent co tion between the cases of typhoid and any one detailed list of foods. Attention was re-directed t staff, none of whom had admitted a history of ty fever. Until the result of Widal and culture tests known, two members of the staff on whom sus fell were suspended from duty as food-handlers drastic hygiene precautions were instituted. Subsequ a history of typhoid fever was confirmed in one of th suspended members of the staff, who was found excreting organisms of Vi-phage type E.1—the found in the outbreak.

Up to noon on Nov. 13 there were 15 confirmed of typhoid and a further 15 in which this diag though still unconfirmed, was hardly in doubt.

Infection has been proved not to be confined t meal on Oct. 6. Over 3000 people who partook of pos infected meals up to Nov. 5 were "at risk."

Smallpox

In Liverpool, a male laboratory assistant, aged 16 who handled glassware contaminated with smallpox modified by egg passage, has developed smallpox. illness started on Oct. 24, and the rash, which is dis and modified, appeared on Oct. 27. Primary vaccin had been performed on Oct. 17, 1949, soon afte began work in the laboratory. The diagnosis has confirmed by the isolation of smallpox virus pustules. The patient was isolated on Oct. 29, and tacts have been vaccinated and placed under surveill

On Nov. 10, the patient's younger brother, 15 years, who was living at the same address in Live

ISTRIBUTION OF GENERAL PRACTITIONERS

e following amendments have been made to the Medical ces Committee's classification of executive-council described in our issue of July 30 (p. 211). Other dments appeared in our issues of Aug. 20 (p. 355) and (p. 633). Schedule 1 contains the names of parts where doctors are needed; schedule 4 of the "closed areas."

Schedule 1

ADDITION

x.—Canvey Island.

DELETIONS

nshire (Lindsey).—Louth.
kshire (East Riding).—Howden, Goole.
outhshire and Newport.—Pontypool, Risca.
tingdonshire.—Ramsey.

Schedule 4

ADDITIONS

t and Canterbury.—Dover R.D.
rthenshire.—Areas immediately adjacent to Henllan and ter.

DELETIONS

kinghamshire.—Haddenham.
wall.—Bude.
setshire.—Kinson.
fordshire.—Braughing.

CORRECTIONS

olnshire (Holland).—Add Gedney Hill.
lesey.—Valley R.D. should read Valley R.D. (excluding ead Island).
efordshire.—Delete Hay-on-Wye.

CIVIL DEFENCE

March, 1948, the Civil Defence Joint Planning Staff set up under the chairmanship of Major-General S. F. ; and in December the Civil Defence Act received the l Assent. Recruitment to the new organisation began week. The four services concerned are the Civil Defence , the Auxiliary Fire Service, the National Hospital ce Reserve, and the Special Constabulary. The National ital Service Reserve is to be concentrated on the hos-; static first-aid posts will be set up only at the hospitals arby, and first-aid to casualties will be given mainly by le first-aid units based on the hospitals. For the moment eserve is open to: (1) trained nurses and midwives, led assistant nurses, and nursing assistants class 1 ing assistants in Scotland); (2) people trained, or willing trained, as nursing auxiliaries; and (3) in Scotland only, lance workers. In England and Wales the ambulance on is part of the Civil Defence Corps.

HOSPITALS' DIRECTORY

New directory,[1] prepared by the Ministry of Health, sets he areas covered by the fourteen regional hospital boards, ther with the names and addresses of the secretaries, and ames and number of beds of hospitals under each management committee, together with the name and address of the tary. Similar information is given about teaching itals. There are also lists of disclaimed hospitals, and stitutions with which regional boards have made contual arrangements. The directory concludes with an abetical list of hospitals and other institutions.

INTERNATIONAL EUROPEAN SOCIETY OF HÆMATOLOGY

E hæmolytic anæmias were the main subject of the nd International Congress of Hæmatology, held at reux on Sept. 15–17. The discussion started with a al survey by Prof. L. Heilmeyer (Freiburg), and with ar presentation of primary hæmolytic anæmia by Dr. W. shek (Boston, U.S.A.), who had observed 63 cases. This followed by more than twenty papers on hæmolytic mia and hæmolytic phenomena studied from various les by physicians, pathologists, and biologists of many ionalities. The second day's discussion concerned anti-otic and cytostatic substances. Dr. P. Dustin (Brussels) ested that mitotic poisons are more important for the hemical study of mitosis than for the control of malignant ase; and Prof. A. Haddow presented a new hypothesis cerning the mode of action of the nitrogen-mustards. L. M. Meyer (New York) said that the folic-acid agonists had not fulfilled the hopes placed in them for the atment of leukæmia. Similar experimental and clinical rvations were repeated in more than a dozen shorter munications. Various other morphological and immunological aspects of hæmatology were reviewed, and the congress ended with an emphatic plea by Prof. K. Rohr for the preservation as far as possible of the classical terminology of the blood and marrow cells. Prof. P. Chevallier (Paris), Prof. P. Lambin (Louvain), and Prof. G. Di Guglielmo (Naples) presided; and Dr. S. Moeschlin (Zurich) deserved great credit for the general arrangements. The next congress of the society will be a joint one with the International Society of Hæmatology, under the presidency of Sir Lionel Whitby, at Cambridge in August, 1950.

University of Birmingham

Prof. G. Haswell Wilson has retired from the chair of pathology. Dr. W. T. Smith has been appointed lecturer in pathology.

Royal College of Surgeons of England

At a meeting of the council on Nov. 10 with Sir Cecil Wakeley, the president, in the chair, Mr. L. C. E. Lindon, of Adelaide, was elected as a temporary member of the court of examiners.

Diplomas of membership were granted to those named in our report of the comitia of the Royal College of Physicians on Nov. 5 (p. 867).

Royal Faculty of Physicians and Surgeons of Glasgow

Dr. A. L. Goodall will open the celebration of the 350th anniversary of the foundation of the faculty on Wednesday, Nov. 23, at 5 P.M., when he delivers the Finlayson lecture on its history. On Nov. 25 the lord provost and corporation of Glasgow will receive the president (Dr. W. R. Snodgrass) and fellows of the faculty, and on Nov. 27 at 10.30 A.M. there will be a special service at Glasgow Cathedral. On Nov. 28, at a reception in the hall of the faculty, the honorary fellowship will be conferred on Prof. E. P. Cathcart, M.D., F.R.S., Sir Hector Hetherington, LL.D., Prof. G. B. Fleming, F.R.C.P., Prof. Hilda Lloyd, F.R.C.O.G., Lord Moran, P.R.C.P., Mr. R. B. Ness, F.R.F.P.S., Dr. W. D. D. Small, P.R.C.P.E., Sir Cecil Wakeley, P.R.C.S., and Mr. W. Quarry Wood, P.R.C.S.E. On Nov. 29 the faculty is giving a commemoration dinner.

Faculty of Ophthalmologists

Some confusion has arisen as a result of two apparently conflicting decisions of the council of this faculty concerning the period of postgraduate training and experience recommended before qualifying as a consultant. In 1946 the three Royal Colleges, having considered the advice of other bodies including the faculty, drew up a list of criteria and agreed on a minimum of five years. Early this year, on a further request from the Joint Committee for Consultants through the Royal College of Surgeons, the council of the faculty gave its opinion that ten years was the necessary period. This was done before it was known that there would not be a division between specialists and consultants. When it was discovered that there would be no division, the decision was rescinded and the original view of five years was confirmed.

Association of Industrial Medical Officers

Dr. L. G. Norman, chief medical officer of the London Transport Executive, has been elected president of this association.

Royal Society

A Royal medal has been awarded to Prof. R. A. Peters, M.D., F.R.S., for his researches on the biochemical rôle of vitamin B_1 in tissue metabolism, and the mechanism of the toxic action of lewisite and other arsenical compounds.

International Control of Morphine Substitutes

A United Nations agreement to place the synthetic morphine substitutes under international control is expected to come into operation early next year. According to B.U.P., the last of the 25 signatures needed to make the agreement effective is expected shortly.

Pavlov Centenary Celebrations

In connexion with this centenary the film *Mechanism of the Brain* will be shown at Guy's Hospital Medical School, London, S.E.1, on Monday, Nov. 28, at 5 P.M. *Academician Pavlov*, which was lately reviewed in THE LANCET (Oct. 29, p. 821) will be shown at the Hammer Theatre, Wardour Street, W.1, on Thursday, Dec. 8, at 7.45 P.M. Tickets may be had from the Society for Cultural Relations with the U.S.S.R., 14, Kensington Square, W.8.

HE DIAGNOSIS OF BONE TUMOURS *

JAMES F. BRAILSFORD
M.D., Ph.D. Birm., F.R.C.P., F.I.C.S.
LTING RADIOLOGIST AND DIRECTOR OF RADIOLOGICAL
DIES IN LIVING ANATOMY, UNIVERSITY OF BIRMINGHAM

> "They that have power to hurt and will do none,
> That do not do the things they most do show,
> Who, moving others, are themselves as stone,
> Unmovéd, cold, and to temptation slow;
> They rightly do inherit Heaven's graces,
> And husband Nature's riches from expense;
> They are the lords and owners of their faces,
> Others, but stewards of their excellence."
>
> *Sonnets*, W. SHAKESPEARE.

HEN the diagnosis of bone tumours depended solely he clinical evidence, limbs were sometimes amputated gh the lesion was benign and would have resolved r efficient treatment. There were no early diagnoses probably no cures.

cause of this and because pathologists had shown dvantages of histopathological examinations in soft-e lesions, it became customary to seek early diagnosis one tumours by biopsy. This practice, however, ys carries important risks, and I believe these should nger be taken now that radiological aids to diagnosis an alternative.

the same time it is clear that radiography can be gravely misused. There has been a tendency ach that radiology is a short cut to diagnosis, which ers preliminary clinical investigation unnecessary even undesirable—that progressive disease is asymp-tic and its detection in the early stages only possible adiography. This in turn has focused attention on radiographic appearances rather than the patient's lition; indeed it has led to treatment of the radio-hic appearances, and sometimes gross neglect of the se. Such erroneous teaching indicates ignorance portant radiographic periods:

The *latent negative radiographic period*—the period between the date of trauma, or the onset of clinical signs and symptoms, and the first appearance of abnor-mality on the X-ray film. (In some cases the clinical signs and symptoms begin to fade before the radiographic signs develop, for there is a lag in the radiographic evidence of resolution as well as of progression.)

The *positive radiographic symptomless period*—the period during which radiography continues to show signs of a lesion, though resolution or complete healing has taken place and the patient is free from symptoms. This period often endures for the remainder of the patient's life.

ertain circumstances the first of these two periods rlaps the second: the radiographic signs of an ve illness have not yet appeared, while those of a ner illness are still conspicuous.

o ignore the clinical evidence and treat the patient rding to the radiographic findings may have serious sequences, and radiography, therefore, should never cede or supplant adequate investigation. The fact ains that the diagnosis of tumours of bone from clinical signs and symptoms alone is almost impossible.

RISKS OF BIOPSY

If biopsy could be proved to result in a prompt curate diagnosis, the risks it involves might be worth king. But in bone lesions it has very serious limitations, d is liable to important erroneous interpretations.

1. Biopsy necessitates an anæsthetic. Though this ay appear of little significance, it is well to remember at some patients die during the exploration of lesions und afterwards to be benign—indeed, by a trick of fate, the exploration of an inoperable carcinoma seems to carry less risk.

2. Biopsy necessitates cutting into the lesion. It is contested that this does not spread malignant cells, but we are all familiar with the dispersal of infective organisms by such surgery: the cutting into a tuberculous focus has been responsible for the subsequent development of tuberculous meningitis. In any condition where the clinical and radiographic features determine the need for resection we should avoid making any unnecessary incision into the lesion. Comparison of radiographic appearances before and after biopsy shows that the surgical incision does disperse malignant cells locally, if not generally; before biopsy we see the disease confined to the bone, but after the cortex of the bone has been cut into we see an irregular periosteal reaction, spicules, and abnormal soft tissue tumours—a sort of explosive effect.

3. Biopsy adds the reactions of trauma to those of the disease. These affect not only the histological features of the lesion but also the serial radiographic appearances which may become much harder to evaluate. It interferes with the normal sequence of changes in bone lesions, which, left undisturbed, may be characteristic and permit of accurate diagnosis.

4. Biopsy removes bony scaffolding which may seriously interfere with the resolution and stability of the affected bone—particularly when it is a "real biopsy" in which an extensive survey of the exposed lesion is made and several pieces of tissue, sometimes of good size, are removed. Needle biopsy is acknowledged, even by the enthusiasts for biopsy, to be of little use for bone lesions.

5. Biopsy does not always provide material on which a reliable opinion can be formed. The material removed may be from bone away from the influence of the pathological process (e.g., normal bone), from bone showing only the reactive changes surrounding the lesion, or from a degenerative part of the lesion. But even when the whole lesion is submitted for histopathological examination to a number of eminent pathologists, we may receive as variable a number of verdicts, ranging from benign to highly malignant. Particularly in the presence of some deficiency, osseous dystrophy, or dysplasia, the histological responses of bone to trauma, inflammation, and neoplastic change may be apparently indistinguishable; and the result of biopsy is that some malignant processes escape detection while some benign lesions are given the significance of malignancy. In any case, the tissue removed represents but a part of the bone at the time of its removal, and from it the pathologist may not be able to estimate its age, assess the essential nature of the change or origin, or determine the rate of growth of the cellular structure. If the lesion has been subjected to any extraneous influence such as trauma, X radiation, or influential medication, the histological findings may be changed accordingly: the extent of the influence of these factors may be impossible to estimate. Too often the pathologist is blamed when it is the material supplied which is responsible for the difficulties. The unreliability of the procedure has never been better demonstrated than in a case where an osteopathologist's biopsy diagnosis of chondrosarcoma had later to be changed to benign ossifying hæmatoma—because the patient was considered unfit for amputation and his lesion had a chance to resolve. The comment made was: "had the limb been amputated in this case no one could have proved that this was not a sarcoma cured by amputation" (Baker 1946)—an admission of the highest significance when evaluating the reliability of biopsy.

6. Biopsy may actually be the cause of delay in surgical treatment. This happens more often than is supposed.

Based on an address delivered at many of the chief medical centres in the United States of America, 1948–49.

London County Medical Society

A clinical meeting of this society will be held at Boxley Hospital, Boxley, Kent, on Wednesday, Dec. 7, at 3 P.M.

General Medical Council

Dr. O. C. Carter has been elected to the council as a direct representative for England for the five years from Nov. 8, 1949. The voting was as follows:

OCTAVIUS CYRIL CARTER, M.B.	12,603
LEON GILLIS, M.B.E., M.CH.ORTH., F.R.C.S. ..	2507
WILLIAM ALEXANDER BRYCE, M.B.	2329

Aureomycin and Chloromycetin Centres

The regional hospital board centres for the distribution of aureomycin and chloromycetin are as follows:

Region	*Distribution Centre*	*Tel. no.*
Newcastle	Newcastle-on-Tyne General Hospital, 418, Westgate Road, Newcastle, 4.	Chief Pharmacist New. 35211
Leeds	Leeds Blood Transfusion Laboratory, The Bridle Path, York Road, Seacroft, Leeds.	Leeds 45091
Sheffield	Ci	Nottingham 66292
East Anglian	Ac Cambridge.	Chief Pharmacist Cam. 1451
North West Metropolitan	West Middlesex Hospital, Twickenham Road, Isleworth.	Chief Pharmacist Hounslow 2311
North East Metropolitan	Mile End Hospital, Bancroft Road, E.1.	Physician Supt. Advance 2873
South East Metropolitan	Grove Park Hospital, Lee, S.E.12.	Lee Green 1077
South West Metropolitan	South London Blood Supply Depot, Benhill Avenue, Sutton, Surrey.	Vigilant 0068
Oxford	Unit Ch	Chief Pharmacist Oxford 48651
South-Western	Ham Hc Bristol.	Bristol 31165
Wales	City Isolation Hospital, Canton, Cardiff.	Med. Supt. Cardiff 960
Birmingham	Selly Oak Hospital, Birmingham.	Med. Supt. Selly Oak 1361
Manchester	Royal Infirmary, Manchester, 13.	Chief Pharmacist Ardwick 3300
Liverpool	Fazakerley Sanatorium, Liverpool, 9.	Med. Supt. Aintree 2321

Liverpool Regional Hospital Board

The probable expenditure of the board on Capital Account for 1949–50 is estimated at £309,801 as against the maximum of £334,000 approved by the Ministry of Health. The under-spending has been occasioned by delays in the commencement of schemes. For 1950–51 two lists are submitted at the Ministry's request, the first totalling £334,000 (i.e., the same as permitted for 1949–50), and the second totalling £167,000 or half this figure. Works in the second category will be undertaken only if the national finances permit. Provisional lists of schemes have also been submitted at the Ministry's request amounting to £668,000 for 1951–52 and £1,002,000 for 1952–53.

The net requirements for the whole of the region for the current year are estimated at £7,658,688, which is £535,384 or 7·5% in excess of the approved figure. Seventeen of the nineteen hospital management committees show increases, £478,958 of which is attributable to salaries and wages. About £111,000 of the latter figure (offset by £26,000 income) is represented by national pay awards to various types of nurses, but the remainder is due to the employment of increased staffs, particularly nurses. The corresponding estimate for 1950–51 is £8,694,864, which is £1,571,560 or 22·1% in excess of this year's approved figure. Provision has been made for the occupation of 1173 additional beds above this year's figure, and about £425,000 may be ascribed to this cause. The remainder of the increase is largely attributable to improvement of standards, particularly in nursing strengths, and development of ancillary services. Provision is sought for the engagement of an additional 1890 employees, of whom 1289 are nurses. The total increase in the salaries and wages bill is £959,963 gross, less certain charges for board-residence. Repairs and maintenance of plant and premises show an increase of £202,842, largely because of the cuts made under this heading for the current year which cannot be repeated. Provisions show an increase of £129,461. In making the estimates no allowance has been made for any general rise in the price level as the result of devaluation except to a very limited extent for the price of bread and flour confectionery.

U.S. Army's Plan to Conserve Doctors

Under a plan adopted by the United States Army view to securing economy in professional staff in hospital personnel will be divided into two trative and professional. The professional group, of doctors, dentists, nurses, and others, will not be to join the unit until this is engaged in the actual care patients; and when the need for this group ceases they be transferred elsewhere while the administrative remains to supervise the moving of equipment and By this plan, out of 47 professional people required for type of field hospital, only 4 will be needed for constant with the unit. All field hospitals will eventually be orga according to this plan.

Prof. T. Pomfret Kilner has left for Turkey where he give a series of lectures sponsored by the British Council the Turkish ministry of health.

HEN the diagnosis of bone tumours depended solely he clinical evidence, limbs were sometimes amputated gh the lesion was benign and would have resolved r efficient treatment. There were no early diagnoses probably no cures.

ecause of this and because pathologists had shown dvantages of histopathological examinations in soft- e lesions, it became customary to seek early diagnosis one tumours by biopsy. This practice, however, ys carries important risks, and I believe these should nger be taken now that radiological aids to diagnosis an alternative.

the same time it is clear that radiography can t be gravely misused. There has been a tendency ach that radiology is a short cut to diagnosis, which ers preliminary clinical investigation unnecessary even undesirable—that progressive disease is asymptatic and its detection in the early stages only possible adiography. This in turn has focused attention on radiographic appearances rather than the patient's lition; indeed it has led to treatment of the radiohic appearances, and sometimes gross neglect of the ase. Such erroneous teaching indicates ignorance portant radiographic periods:

The *latent negative radiographic period*—the period between the date of trauma, or the onset of clinical signs and symptoms, and the first appearance of abnormality on the X-ray film. (In some cases the clinical signs and symptoms begin to fade before the radiographic signs develop, for there is a lag in the radiographic evidence of resolution as well as of progression.)

The *positive radiographic symptomless period*—the period during which radiography continues to show signs of a lesion, though resolution or complete healing has taken place and the patient is free from symptoms. This period often endures for the remainder of the patient's life.

ertain circumstances the first of these two periods rlaps the second: the radiographic signs of an ve illness have not yet appeared, while those of a ner illness are still conspicuous.

o ignore the clinical evidence and treat the patient rding to the radiographic findings may have serious sequences, and radiography, therefore, should never ede or supplant adequate investigation. The fact ains that the diagnosis of tumours of bone from clinical signs and symptoms alone is almost impossible.

RISKS OF BIOPSY

If biopsy could be proved to result in a prompt curate diagnosis, the risks it involves might be worth king. But in bone lesions it has very serious limitations, d is liable to important erroneous interpretations.

1. Biopsy necessitates an anæsthetic. Though this ay appear of little significance, it is well to remember at some patients die during the exploration of lesions und afterwards to be benign—indeed, by a trick of fate, the exploration of an inoperable carcinoma seems to carry less risk.

2. Biopsy necessitates cutting into the lesion. It is contested that this does not spread malignant cells, but we are all familiar with the dispersal of infective organisms by such surgery: the cutting into a tuberculous focus has been responsible for the subsequent development of tuberculous meningitis. In any condition where the clinical and radiographic features determine the need for resection we should avoid making any unnecessary incision into the lesion. Comparison of radiographic appearances before and after biopsy shows that the surgical incision does disperse malignant cells locally, if not generally; before biopsy we see the disease confined to the bone, but after the cortex of the bone has been cut into we see an irregular periosteal reaction, spicules, and abnormal soft tissue tumours—a sort of explosive effect.

3. Biopsy adds the reactions of trauma to those of the disease. These affect not only the histological features of the lesion but also the serial radiographic appearances which may become much harder to evaluate. It interferes with the normal sequence of changes in bone lesions, which, left undisturbed, may be characteristic and permit of accurate diagnosis.

4. Biopsy removes bony scaffolding which may seriously interfere with the resolution and stability of the affected bone—particularly when it is a "real biopsy" in which an extensive survey of the exposed lesion is made and several pieces of tissue, sometimes of good size, are removed. Needle biopsy is acknowledged, even by the enthusiasts for biopsy, to be of little use for bone lesions.

5. Biopsy does not always provide material on which a reliable opinion can be formed. The material removed may be from bone away from the influence of the pathological process (e.g., normal bone), from bone showing only the reactive changes surrounding the lesion, or from a degenerative part of the lesion. But even when the whole lesion is submitted for histopathological examination to a number of eminent pathologists, we may receive as variable a number of verdicts, ranging from benign to highly malignant. Particularly in the presence of some deficiency, osseous dystrophy, or dysplasia, the histological responses of bone to trauma, inflammation, and neoplastic change may be apparently indistinguishable; and the result of biopsy is that some malignant processes escape detection while some benign lesions are given the significance of malignancy. In any case, the tissue removed represents but a part of the bone at the time of its removal, and from it the pathologist may not be able to estimate its age, assess the essential nature of the change or origin, or determine the rate of growth of the cellular structure. If the lesion has been subjected to any extraneous influence such as trauma, X radiation, or influential medication, the histological findings may be changed accordingly: the extent of the influence of these factors may be impossible to estimate. Too often the pathologist is blamed when it is the material supplied which is responsible for the difficulties. The unreliability of the procedure has never been better demonstrated than in a case where an osteopathologist's biopsy diagnosis of chondrosarcoma had later to be changed to benign ossifying hæmatoma—because the patient was considered unfit for amputation and his lesion had a chance to resolve. The comment made was: "had the limb been amputated in this case no one could have proved that this was not a sarcoma cured by amputation" (Baker 1946)—an admission of the highest significance when evaluating the reliability of biopsy.

6. Biopsy may actually be the cause of delay in surgical treatment. This happens more often than is supposed.

Based on an address delivered at many of the chief medical centres in the United States of America, 1948–49.

In one case I recorded, the diagnosis of osteogenic sarcoma was made from the characteristic radiographic features, but there was seven months' delay in amputation because of failure to obtain histological evidence of tumour or malignancy, despite exploratory biopsy and resection of the large abnormal bony mass as completely as possible. *The idea prevails that biopsy facilitates early diagnosis, and early diagnosis permits of precipitate amputation*; yet this patient was subjected to three unnecessary exploratory operations in the seven months' interval between the radiological diagnosis and the belated amputation.

THE SURGEON'S RESPONSIBILITY

In view of the foregoing risks I would *suggest that*, before doing any biopsy, the surgeon should *(a)* undertake to act on the pathologist's findings, *and (b)* plan the operation he would consider necessary if malignant *disease is reported*, and *(c)* obtain the necessary permission *of the patient* or relatives.

If he is going to quibble over the pathologist's report, even to the extent of sending the preparations to other pathologists *for opinions*, or if the patient or relatives are going to deny him *permission* to do what he thinks essential, he ought not to do the biopsy *at all*; *for it will be useless and will inflict* unnecessary mental and physical pain without conferring the slightest benefit on the patient. Sometimes, after receiving *a biopsy report* that a lesion was malignant, surgeons have *attempted* a local removal, either because they hoped it *might* be successful or because they did not wish to bear the responsibility *of* mutilating the patient. But if a lesion, clinically *and* radiographically, appears to be localised *would it not be better to do a localised resection in the first instance, instead of having a first operation to cut a bit out and then have to face the risks and anxieties of a second?* The resected lesion can then be sent entire to the pathologist, who will have a better chance to study its character. Whatever the pathologist's report, the surgeon has the satisfaction of knowing that his surgery was designed to remove the entire lesion without dispersing the pathological tissue. The patient is better off than he would have been after a biopsy, for the surgeon has now the choice of waiting and watching the subsequent development, or of amputating the limb if he considers that necessary, and he has the patient's consent.

Many lesions resected in this manner, though reported as malignant from the histological characters, have proved to be benign and the patient has suffered no further disturbance. There have also been cases where the patient has died of metastases, though his lesion was *reported as histologically benign*.

If any surgical intervention is to be undertaken, the surgeon should ask for *radiological localisation and skin markings*; *for the position of a lesion in a bone relative to the skin can be very confusing and a skin localisation* saves time and assists efficiency.

RADIOGRAPHY OF BONE TUMOURS

Our knowledge of the radiographic appearances of many bone lesions has been built up from continuous studies of their course to destruction or resolution, aided by the pathologist's contributions on isolated cases. As I have shown elsewhere (Brailsford 1948a), many bone diseases and tumours have characteristic radiographic appearances which allow of ready identification. On the other hand I am well aware that different kinds of lesions may have radiographic features which are indistinguishable from one another; and that is why I disapprove of the practice of encouraging students to make a "spot" diagnosis from one film. Sometimes the development of a lesion must be watched clinically and *radiographically*, over a period depending on its of change, before coming to any conclusion. To *who crave early diagnosis* this appears as pr *and they blame it for contributing to the high mortality from osteogenic sarcoma*; but I have myself that the earliest diagnosis of this prompt amputation does not ensure cure.

Indeed, I have set out to detect evidence of osteog sarcoma at the earliest possible moment (sometimes the first visit of a patient whose symptoms or si have been present but a few weeks, as was suppor by the nature and extent of the radiographic chang and get amputation quickly; yet in no such case the patient survived—death has occurred within years with metastases. In some cases metastases ca demonstrated in the lungs on the first visit of a pa complaining of a localised lesion of recent origin, it is the experience of most surgeons who have d with a number of cases of osteogenic sarcoma t metastases and death follow prompt amputation

But if precipitate or prompt amputation does ensure cure, it may certainly involve the loss of a for a benign lesion, which, left untouched, would resolved. Such an accident indicates undue haste, insufficient and sometimes inefficient clinical and ra graphic observation. It is said that by watching waiting for the diagnosis to be established clinically radiographically, you jeopardise the patient's chances cure if the lesion should turn out to be malignan but I nevertheless believe the delay to be justifia In my experience, when the clinical and radiograp evidence was inconclusive, the histology was equ confusing. No-one can prove that the delay resulte the patient's death. MacDonald (1949) recently st that figures from the Registry of Bone Sarcoma sho "that more of the cured than the fatal cases had bio done one day to five years before amputation." O *workers have said that patients who sustained than one biopsy lived longer than those who had* or but one. I cannot understand such reasoning. patient with a lesion which clinically and radiographic was an osteogenic sarcoma would not have needed biopsy; certainly not more than one. Do not mult biopsies mean indecision and inconclusive evidence? my experience biopsy has hastened, rather than reta *the development of osteogenic sarcoma.* The esse claim made for biopsy is that it permits of early diagn but actually it may confuse and seriously delay recognition of malignant disease (Brailsford 1948b).

My thesis is that careful clinical examination radiography by experienced workers will enable th to give an early and accurate diagnosis without cau the patient any pain and without the consequence surgical trauma. Sometimes the radiographic evid is conclusive at the first examination. In other c first radiographs in themselves do not permit of a def *diagnosis, but in the light of the clinical history* t may be very *suggestive.* For instance, where the his is of a definite trauma and the radiographs show cha which could have been produced by that trauma, it very unlikely that malignant metaplasia has occur in the tissues; for trauma as the immediate cause sarcoma is very very rare. I am fully conscious of t fact that, in many cases of sarcoma, the history trauma is given; but it is usually possible to see fr the radiographic appearances that the trauma me drew attention to a pre-existing lesion. That sarc can arise at the site of an old injury, or within a fo of disturbed ossification (e.g., in the dysplasias of bo I have much evidence to prove. But if the trau is recent the probability is that it has initiated inflammatory focus and that suitable *immobilisatio* and chemotherapy will soon confirm this without an rt to surgery. Too often is the diagnosis of Ewing's ōma made of a syphilitic or other inflammatory s in bone because of certain ill-understood radio- hic features, perhaps supplemented by histological nination of material removed at biopsy. Before hing such a diagnosis it is particularly important xclude all possibilities of an inflammatory focus, ı to the extent of administering appropriate medica- , for the reports on serum reactions cannot always elied on, and the only other alternative—amputation deep X-ray therapy—are no cures for a Ewing's oma or syphilis.

is important to remember that the presence of a plasia of bone does not confer immunity to trauma, iency, endocrine, inflammatory or neoplastic com- ations; and in some cases only a double diagnosis explain the unusual clinical and radiographic features the confusion in the histopathology. The possibility ı localised destructive process in a bone being a astasis from a carcinoma must always be considered, the response of such a lesion to a reasonable dose of ays may well be worth seeking—especially as the m which will respond to such radiation will not ire the dosage to be pushed to skin tolerance.

mong the many radiographic features which often to distinguish the nature of lesions in young people he integrity of the growth cartilage. The malignant wth is often limited in its extension by this, though adjacent diaphysis or epiphysis may be seen to be lly infiltrated. The most common transgressor ugh the growth cartilage, even in the early stages lesion, is the tubercle bacillus—a fact which is often reat diagnostic help.

hough from a study of many cases the gross histo- ical features can be suggested, it is not usually possible the radiologist to offer a histological diagnosis. He contributed his maximum for the good of his patient n he has reported to his colleagues that the lesion enign or malignant: the enumeration of conditions, ed on histological features, which it might be, is s-work, and of little value to his surgical colleagues. it is histological features which the latter seeks, he obtain them from a more reliable source.

n the past the responsibility for the diagnosis has n passed to the pathologist. I believe that surgeon, hologist, and radiologist all have their responsibility l only by a full recognition of that responsibility the patient receive the best treatment.

SUMMARY

n the diagnosis of bone tumours, biopsy has serious itations and risks. On a mistaken interpretation, a limb y be amputated for a lesion which would have resolved eft undisturbed.

Usually a local resection of the entire lesion is preferable biopsy.

Certainly no surgeon should undertake biopsy unless is prepared to accept the pathologist's findings and eady has the patient's consent to the operation these tate.

The best and safest means of arriving at an accurate agnosis is clinical observation, aided by serial radio- aphic studies.

Though this observation may involve some delay, ere is little reason to suppose that more immediate eatment would improve the patient's chances of rvival if his lesion is malignant. If his lesion is not alignant, an accurate diagnosis may save his limb.

MAJOR, R.A.M.C., MEDICAL SPECIALIST

THE accidental discovery by Smadel et al. (1948) that 'Chloromycetin' was effective in the treatment of typhoid fever was confirmed by Woodward et al. (1948), and a small number of favourable reports have since been published in the United Kingdom (Bradley 1949, Murgatroyd 1949). A limited amount of the drug was made available for use in British military hospitals in the Middle East Land Forces. We here describe the results obtained in the British Military Hospital, Fayid, in a small series of cases from the Suez Canal Zone of Egypt.

CLINICAL MATERIAL AND SELECTION OF CASES

Typhoid and paratyphoid fevers are endemic in Egypt, and tend to occur sporadically and in small outbreaks of three or four cases among military and Royal Air Force personnel and families. The 25 cases recorded here were seen between February and September, 1949. All the patients had been protected by T.A.B. inoculation, though 3 had not had booster doses within the preceding twelve months.

The original intention was to carry out a controlled trial. However, the untreated control (case 2) of the first case treated with the drug became so desperately ill that it was deemed unjustifiable to withhold chloromycetin, and there is little doubt that it saved his life. After this it was decided to give the drug only to the most severe cases.

Future severity is difficult to assess in the early stages of typhoid, but experience showed that (1) a high maintained fever, (2) severe toxæmia with delirium, prostration, and repeated vomiting, and (3) the occurrence of complications, augured unusual severity when present in the early stages of the illness; in any event such cases run a long course, imposing a heavy strain on their resources, resulting in great debility and prolonged convalescence. This was the basis of selection for chloromycetin therapy.

Salmonella typhi was isolated from the blood in all cases except no. 9 in which it was grown from the fæces, and no. 14 in which the diagnosis was confirmed by agglutination reactions. This last case was treated at a civil hospital under the supervision of Lieut.-Colonel A. P. Trimble, R.A.M.C.

Of the 25 cases, 14 were treated with chloromycetin, and of these 3 had relapses which were similarly treated. In addition we treated 1 case each of paratyphoid A and B fevers, with results identical with those obtained in typhoid. In 11 cases chloromycetin was not given. The 2 most severe of these (nos. 15 and 16) occurred before we had the drug: one died of a perforation after a very stormy course, while the other relapsed ten weeks after becoming afebrile, but eventually recovered.

DOSAGE AND ADMINISTRATION OF CHLOROMYCETIN

Chloromycetin (Parke Davis & Co.) (chloramphenicol) was dispensed in capsules containing 0·25 g. for oral administration. Each course started with a dose of approximately 50 mg. per kg. body-weight (10–14 capsules). Vomiting, delirium, and lack of coöperation often made it difficult to administer this large dose, and it would have been an advantage to have a preparation for parenteral injection. In one case it was necessary to pass a Ryle's tube and inject an aqueous suspension of the drug into the stomach. After the initial dose

Most of the terms and symbols used are self-explanatory. "Length of illness" refers to the time from the onset of symptom the last day of fever.

The symbol (+) is used where the symptom, &c., was present but to an insignificant extent: + = mild, + + = moderate, + + + = sev + + + + = very severe.

capsule was given every two hours until the tem- ture fell to normal, and thereafter every four hours mplete the course of 20–22 g., varying according to size of the patient and the response to treatment. verage course took nine days.

eneral treatment followed accepted lines. Patients nursed in air-conditioned wards at a temperature 0–80°F (the day temperature outside often being over 100°F), and small frequent feeds were given of gh-calorie, low-residue bland diet with adequate rals, vitamins, and fluids. When there was respira- infection of more than trivial degree, penicillin was 1; but it was not observed to make any difference e the typhoid infection remained active.

l treated cases were kept in bed for 14 days or more the fever had subsided, and by this time all but most severe had become very active in bed (in ked contrast to untreated cases). Exercises and sage were started in all cases within a week of rvescence.

CASE-HISTORIES

he main features of all 25 cases are summarised in accompanying table. We do not regard the untreated s as controls, but it is nevertheless instructive to pare the two groups.

bbreviated clinical charts of the following cases are n in fig. 1.

ase 1.—*A severe case with dysenteric onset.* Male, aged 26, oral, R.A.F. He had been admitted to another hospital 4 days' history of bloody diarrhœa; this was unsuccess- treated with sulphonamides, and no pathogenic organisms found in the stools. He became steadily worse, more and dehydrated, and was transferred to our hospital he 14th day of illness as a case of "clinical enteric." admission he was very ill, emaciated, confused, and ly incontinent; he had severe pea-soup diarrhœa, and ores. *S. typhi* was grown on blood-culture. Chloro- etin treatment began on the 17th day of illness, and he afebrile 4 days later, though he did not recover sphincter rol till the 28th day. By the 33rd day he was mentally e normal, eating heartily, and gaining weight. He started t up on the 46th day, and was discharged to convalescent t on the 75th day.

ase 2.—*A very severely toxic case with intestinal hæmorrhage.* e, aged 20; aircraftman, R.A.F., admitted to hospital r a collapse at work, with several weeks' history ague ill health and headaches, and 10 days' muscular s and sweating (taken to indicate the onset of the illness). general condition was good, and there were no physical s except fever. *S. typhi* was grown from the blood. the 16th day of illness he developed a confluent rash on k and limbs, and deteriorated steadily thenceforward l on the 25th day he had pea-soup diarrhœa and was tional and incontinent. Though he was a "control" it was deemed unjustifiable to withhold chloromycetin longer, and on the 27th day administration was started. he next 48 hours he had gross intestinal hæmorrhage ut 4 pints in all); a continuous intravenous glucose- e drip was instituted, and he also received 4 pints of d, the latter causing severe rigors. He developed con- lation at both lung bases, and the outlook was considered less. On the 30th day, after a rigor, he was thought e dying, but he rallied in two or three hours, and improve- t began from that time. He was very weak and remained ntinent until the 50th day; he was also found to have kness of his left anterior tibial muscles (probably due to ritis). He started to get up on the 70th day, and was alided to the U.K. on the 93rd day, fully ambulant and ning weight and strength but having tachycardia on rtion.

Case 5.—*A severe case with a relatively mild relapse.* Male, d 21; aircraftman, R.A.F., admitted with 4 days' history nausea, constipation, and headache. There were no physical ns except fever: *S. typhi* was grown on blood-culture. He came rapidly worse with incontinence, profuse vomiting, d delirium. Chloromycetin was commenced on the 7th day; started to improve 2 days later, was afebrile on the 12th y and mentally normal on the 13th. Progress was unevent- l until the 35th day when he had evening fever, and for the next 3 days his temperature mounted steadily. *S. typhi* were grown on blood-culture on the 38th day, and chloromycetin was recommenced on the 40th. He had moderate meteorism and vomiting. Temperature was normal on the 43rd day, and convalescence was thereafter uneventful; he got up on the 61st day and was discharged to convalescent depot on the 82nd.

Case 6.—*A typical case of moderate severity with a long prodromal period.* Male, aged 38; major, R.A.S.C. 18 days before admission he had a few days' fever and headache, which improved, and then became much worse 3 days before admission. There were no physical signs except fever: *S. typhi* were grown on blood-culture. He rapidly became worse, and was mentally irritable and negativistic. Chloromycetin was begun on the 21st day, and his headache and mental condition improved 2 days later. He was afebrile on the 25th day, and free from symptoms. Further convalescence was uneventful: he got up on the 40th day and was discharged to convalescent depot on the 59th.

Case 10.—*A severe case treated early, with a very severe relapse complicated by bronchopneumonia.* Female, aged 26; aircraftwoman, W.R.A.F. Admitted from another hospital with 8 days' history of headache and fever; *S. typhi* had been grown from the blood on the 4th day. She had a tumid abdomen with rose spots and a palpable spleen. She became more ill, with vomiting and delirium, and chloromycetin was commenced on the 10th day. She started to improve 2 days later, was afebrile the next day, and thereafter appeared to progress satisfactorily. On the 24th day she complained of retrosternal pain and was very miserable, and for the next few days her evening temperature was about 99°F. From the 31st day the fever increased rapidly, and on the 32nd day *S. typhi* were grown on blood-culture.

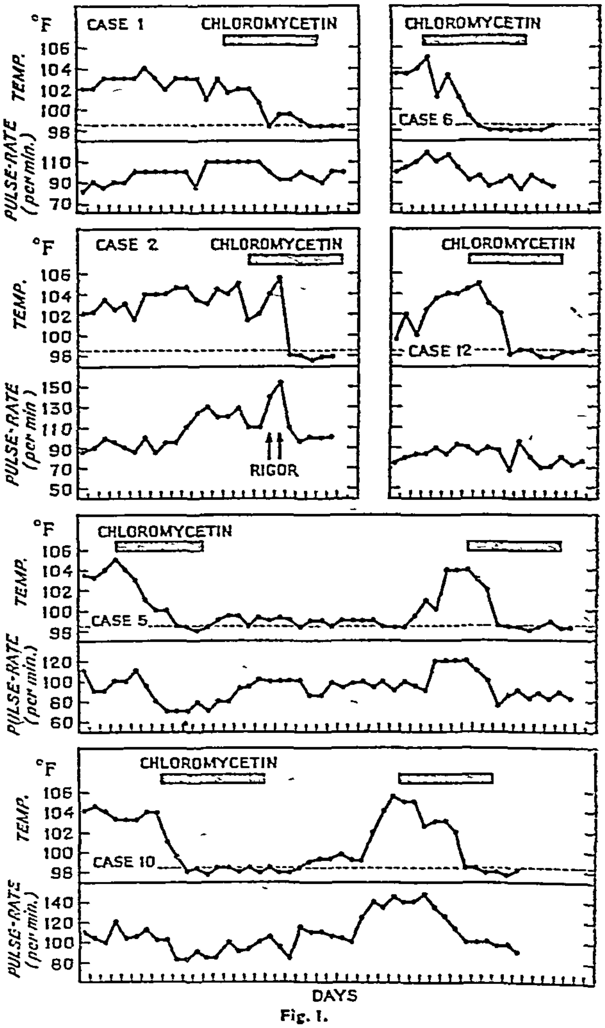

Fig. 1.

By this time she had high fever with severe headache, abdominal distension, vomiting, respiratory distress, and prostration. There were signs of confluent bronchopneumonia in both lungs. Her temperature remained high and her general condition slowly deteriorated. Chloromycetin was recommenced on the 33rd day, but deterioration continued until the 38th day, when there was a slight but definite improvement. The following day she was afebrile and mentally normal, but very weak. Convalescence was uneventful: she started to get up on the 53rd day, and was invalided to the U.K. on the 70th day, ambulant and gaining weight rapidly.

Case 12.—*A case of average severity without complications.* Male, aged 21; lance-corporal, Lancers. Admitted with 4 days' history of headache, malaise, fever, and backache. His spleen was palpable, and *S. typhi* were grown on blood-culture on the 8th day. He became drowsy, with meteorism and occasional vomiting, and chloromycetin was begun on the 11th day. 2 days later he was still very ill and passing fluid stools, but his temperature was beginning to subside. On the 15th day he was afebrile and much improved generally. He started to get up on the 33rd day, and was discharged to convalescent depot on the 55th day.

EFFECTS OF CHLOROMYCETIN IN TYPHOID FEVER

The temperature is the most reliable objective guide to the progress of typhoid fever, and the temperature charts in fig. 1 show clearly the almost dramatic effect of the drug in bringing about rapid defervescence. It can be seen from fig. 2, furthermore, that there is no material difference in the speed of reaction at any stage of the illness: in no case did the fever persist for more than 5 days after administration of the drug was started.

In the less toxic cases the general improvement keeps pace with defervescence, but in the more severely ill it is naturally retarded. In case 2, for example, chloromycetin therapy began on the 27th day of illness, and though defervescence took place in 3 days, mental confusion persisted for 13 and urinary incontinence for 23. Blood-pressure tended to drop as the temperature fell, but rose after a few days to a level higher than that maintained during the febrile stage.

Where toxæmia was relatively mild the first improvement was a subjective one: headache and malaise diminished, and symptoms of respiratory infection subsided. This happened remarkably constantly within 48 hours. The more toxic patients, who were mostly delirious responded less dramatically, but even in them some degree of improvement was discernible on the second day of treatment: vomiting and became less troublesome, and there was partial clearing of consciousness. Appetite usually to return in 4–6 days, and was soon voracious.

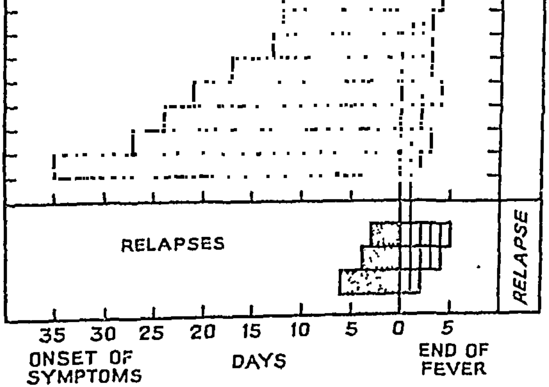

Fig. 2.

Whereas in the earlier and less severe cases the striking effect of chloromycetin is the curtailing length of illness, in the later and very severe accent is on the saving of life. Our cases 2 and 14 regarded as moribund at or soon after the beginning chloromycetin therapy, and case 10 was almost desperately ill during her relapse. In our opinion th patients would have been unlikely to recover with chloromycetin.

In the three relapses in our treated cases chloromyc was just as effective as in the original attack. It noteworthy that the severe respiratory infection was the most important feature of case 10's rel responded within five days of the start of chloromyc therapy, pari passu with the signs and symptoms abdominal infection and toxæmia. Though peni was given in this case there was a strong clinical im sion that the relief of typhoid toxæmia by chloromy was the predominant factor permitting recovery of concomitant respiratory infection.

The effect of chloromycetin on complications ca be judged on so small a series. The complications extreme debility (*bedsores, skin sepsis, parotitis,* should, of course, be reduced almost to vanishing-po As in the case mentioned above, respiratory infecti (which is so constantly present that it should be look on as part of the disease rather than as a complicati was usually relieved by chloromycetin, like the o clinical manifestations of typhoid fever. Perfora did not occur in any of our treated cases, but there intestinal hæmorrhage during treatment in one pa (case 2), and after treatment in another (case 3), ciding with the onset of a relapse. Both hæmorr and perforation have been reported by Woodward (1948), who point out that the intestinal lesions re time to heal after the arrest of the active infection.

Clinically speaking, the effect of chloromycetin se to be to arrest the disease at whatever stage it reached, and to sterilise the blood at the same ti defervescence takes place within five days, and valescence then starts. In consequence a patient tre fairly early in his illness is spared much of the drawn- fever and toxæmia associated with the classical pic of typhoid, and begins his convalescence with relati little debility. He also has much more strength which to meet late complications and relapse, if occur. After 14 days free of fever it is usually neces to curtail rather than encourage activity, and the ea *return of appetite is noteworthy.* It is fair, in fact say that the period of convalescence is halved by tr ment with chloromycetin within the first two weeks the illness.

As regards late cases, so much damage has alre been done here that, as we have said above, the acc is inevitably on the saving of life; but even in th cases the total length of the illness must be considera diminished.

No toxic effects were observed in patients giv chloromycetin. Nausea and vomiting were present, i at all, before the drug was given. No particular effec were noted on the blood picture or the urine.

It is obvious but worthy of comment that chlo mycetin considerably eases the heavy burden that typh fever imposes upon the nursing staff, and in these da of universal shortage of nurses this is not the least the benefits it confers.

Our results and clinical observations cannot be treat statistically. In general, however, they are in accord with those of Woodward et al. (1948).

SOME COMMENTS

age.—The fact that relapses are seen in treated s suggests that the dosage used was not optimal, when the drug is more plentiful larger doses might iven with advantage. The present initial dose is it as much as a severely ill patient can manage. the effect of increasing the dose after a few days, the patient is fitter, might be tried.

lapses occurred in 3 cases, all of which had been ed early in the disease and responded rapidly. It s possible that early treatment does not allow the levelopment of immunity. This suggests a profitable of investigation which we have not been able to w up.

rly Diagnosis.—Now that an effective specific treat- t is available for the enteric fevers, the importance rly diagnosis is apparent. In parts of the world e "P.U.O." is inevitably one of the commonest ical diagnoses on admission to hospital, and where enteric fevers occur sporadically, early diagnosis nds on early blood-culture.

wing to the usually insidious onset of the enteric rs, and the difficulties of early diagnosis, it will be for treatment to commence earlier than the second k of the disease.

anagement.—Despite the efficacy of chloromycetin, re impressed by the fact that typhoid fever remains vere and potentially dangerous disease. calling as in past for a high degree of skill and vigilance on the of the medical and especially the nursing attendants.

SUMMARY

series of 25 cases of typhoid fever is presented. Of 14 treated with chloromycetin, 3 relapsed but res- ded to a second course. There were no deaths in treated cases, 1 in the untreated.

general terms the effect of chloromycetin was to ninate the fever within five days, and to arrest the gress of the disease at the stage reached.

o toxic effects were observed with chloromycetin.

hloromycetin appears to be an effective agent against hoid fever, which nevertheless remains a severe ase.

e wish to express our gratitude to Brigadier W. R. D. hilton, O.B.E., consulting physician, Middle East Land es, who suggested and made possible this investigation, whose advice and encouragement at all stages have n invaluable; to Lieut.-Colonel A. P. Trimble, R.A.M.C., er i/c medical division, for granting us every facility to y on the work and for allowing us to include case 14 providing us with the case-notes; to the Officer Com- ding the Central Pathological Laboratory, M.E.L.F., and staff, for carrying out the pathological and bacteriological estigations; and to the nursing officers and nursing erlies for their ready coöperation in the midst of their ting duties.

e are indebted to Colonel W. J. Officer, O.B.E., commanding British Military Hospital, Fayid, and to the Director of dical Services, Middle East Land Forces, for permission to lish this paper.

MALIGNANT DISEASE OF THE THYROID GLAND

KATHARINE M. BRANSON
M.S. Lond., F.R.C.S.
LATE SURGICAL REGISTRAR, THE ROYAL CANCER HOSPITAL, LONDON

W. HOUSTON
M.D., M.Ch. Dubl., F.R.C.S., F.R.C.S.I.
LATE HON. REGISTRAR, ST. PAUL'S HOSPITAL; LATE SURGICAL REGISTRAR, THE ROYAL FREE HOSPITAL, LONDON

INTEREST in diseases of the thyroid gland has lately been focused mainly on the possibility of controlling thyrotoxicosis by non-surgical means. This seems to be an opportune time to show that nodular goitre must be treated by surgery, whatever views one may hold on the best method of dealing with the toxic types.

The cases reviewed here comprise all the cases of goitre admitted in 1931–44 under the care of the late Cecil Joll to the Royal Free and Royal Cancer Hospitals in which malignancy was finally diagnosed. We hope that the evidence brought forward will convince the reader that *a localised nodule in the thyroid gland should be regarded* in the same way as a localised nodule in the breast and submitted to histological examination as soon as possible.

INCIDENCE

The malignant adenoma is the commonest malignant neoplasm of thyroid tissue. Graham (1925) states that this tumour constitutes 85% of all carcinomata of the thyroid gland, and his findings have been accepted by most other workers. Hence it is this group whose detection and cure offer the greatest scope and the best results in the war against thyroid carcinoma.

Lahey (1941), who also emphasises that most thyroid carcinomata arise in adenomata, has always advocated the removal of adenomata to forestall malignant change. The patient's age or the size of the adenoma gives no guarantee that it is not malignant. Cattell (1946) states that "it is well recognised that malignant disease of the thyroid most frequently arises in the discrete fœtal adenoma. *All* should be removed irrespective of the age of the patient or the size of the adenoma."

That this advice is sound is shown by the fact that almost every writer on this subject emphasises the difficulty of diagnosis. This is not surprising when one remembers that, in Graham's classical paper (1925), photomicrographs of different parts of the same malignant adenoma are reproduced which show all the varied histological pictures from simple colloid adenoma to frank cancer.

Cole et al. (1945) found that 24% of solitary nodules in the thyroid gland, but only 11% of the multinodular type, showed features of malignancy. This incidence is considerably higher than that quoted by most other workers:

Joll (1932) estimated the incidence of malignant change in adenoma at 1%. Cattell (1946) states that about 4% of discrete thyroid adenomata show histological evidence of malignancy. Ward (1944) gives the incidence as 4·8%. Pemberton and Lovelace (1941) found malignancy in 11·4% of cases diagnosed as fœtal or papillary cystadenoma. Balfour estimated the incidence at 1·6%, and Mears at 3·2%. in nodular goitre (both cited by Lahey et al. 1940).

One of the most interesting studies in this connexion is that of Hinton and Lord (1946), who compared the solitary nodule in the thyroid gland with that in the breast. They found, from 200 consecutive biopsies of tumours of the breast at the New York Hospital, that 6·7% of clinically benign lesions were malignant, but in their own series of 184 clinically benign nodular goitres 7·6% were cancerous. They state emphatically that

"All non-toxic nodular goitres—single or multiple—should be removed surgically because of the high incidence of unsuspected cancer, a rate which exceeds that of cancer of the breast in the clinically benign group."

Much of this work is American; it may therefore disarm criticism if the figures of the Royal Free Hospital (table I) are given, since diseases vary somewhat in different countries.

TABLE I—THYROID NEOPLASMS AT THE ROYAL FREE HOSPITAL

Type of neoplasm	Year								Total
	1931	1932	1933	1934	1935	1936	1937	1938	
Localised nodular goitre	32	37	28	35	28	47	37	34	278
Generalised nodular goitre	23	16	41	4	10	31	37	47	209
Retrosternal adenoma	..	..	..	2	6	1	1	..	10
Malignant adenoma	..	..	3	3	..	5	9	13	33
Total adenomata ..	55	53	72	44	44	84	84	91	530
Other forms of thyroid carcinoma	6	2	..	1	6	5	6	6	32

Table I shows that in eight years there were 530 nodular goitres, which included 33 malignant adenomata—an incidence of 6·2%. The incidence of other forms of thyroid carcinoma (32) in this series is 6·0%. The figures in table I support our previous statement that there is a sufficiently high rate of malignant change in thyroid adenomata to render excision of all such nodules advisable.

However, lest it be objected that careful clinical diagnosis and observation should enable one to predict the possibility of malignancy in a given nodule, we examined the case-records of 44 patients with non-toxic nodular goitre in which a malignant change in a nodule was ultimately diagnosed. In these a clinical diagnosis of possible malignancy had been made in only 3 cases. These cases were all seen in a clinic where large numbers of goitres were being seen regularly, and so, if such diagnosis were possible, the conditions were ideal. When it is remembered that the earliest histological sign of malignant change is invasion of the veins, and that invasion of the capsule is a comparatively late sign, it will be obvious that even the best clinician cannot expect to make even a small proportion of correct diagnoses, and all writers on this subject are agreed that, even under the microscope, the difficulties may tax the skill of the pathologist to the utmost.

Most of the histological examinations in this series were performed by the same pathologist; thus a desirable uniformity has been achieved. The main difficulty lies in the criteria adopted for classifying adenomata as malignant, and in this series the standards suggested by Vaux (1937) have been largely adopted. In the main these correspond to Graham's (1925) original work, and it was accepted that 60% of such cases could be diagnosed on morphological grounds, while, in the remainder, invasion of the blood-vessels, or the close relation of the neoplastic cells to vascular endothelium, was accepted as evidence of malignancy.

RESULTS OF OPERATION

It now remains for us to show that operation carries a negligible mortality, and that its results are good.

Mortality

In the years for which complete records are available at the Royal Free Hospital—i.e., in 1931–38 inclusive—there were 334 operations for non-toxic localised nodular goitre and malignant adenomata, with 2 deaths—a mortality of 0·6%. In the same period there were 197 operations for non-toxic generalised nodular goitre, with 3 deaths—a mortality of 1·52%. Among them were 10 retrosternal cases, with 1 death. If we these, there were 187 operations, with 2 dea mortality of 1·07%. Many of these were "bad cases which had been referred for that very hence the mortality-rate cannot be said to be too

In the same period operations of various types performed on 32 cases of carcinoma of the thyr without a single death, a fact which shows the safety biopsy.

Follow-up Results

Table II shows the follow-up results of operati in those cases of thyroid carcinoma from the se which we examined in person. In all of them malignan was proved histologically, but the cases are divided two groups according to whether malignancy was was not suspected preoperatively.

The results of operation in the cases where malignan had not been suspected were almost uniformly goo whereas once signs of malignancy had appeared t prospects of cure were much reduced. We do not im that treatment of thyroid carcinoma is hopeless, fo certain types the results are good, and some wo —e.g., Lahey et al. (1940)—have found a better surv rate in cases of papillary adenocarcinoma than in of adenomata in which malignancy had been diagn on the invasion of blood-vessels. Ward (1944) clai that his 5-year cures were 20% if malignancy had b diagnosed or suspected before operation, 40% if it been first suspected at operation, and 80% if it only been revealed by histological examination of specimen obtained at operation.

Our figures (see below) show that, where full rout treatment—i.e., operation and postoperative irradiati —was given, the survival-rate for all forms of thyr carcinoma was surprisingly high, and for malign adenoma almost uniformly excellent.

TABLE II—FOLLOW-UP RESULTS OF OPERATION IN CASES THYROID CARCINOMA IN WHICH MALIGNANCY WAS UNSUSPECTED, AND (B) SUSPECTED ON CLINICAL GROU BEFORE OPERATION

Condition at follow-up	Years since operation								To

Malignant Adenomata (50 Cases)

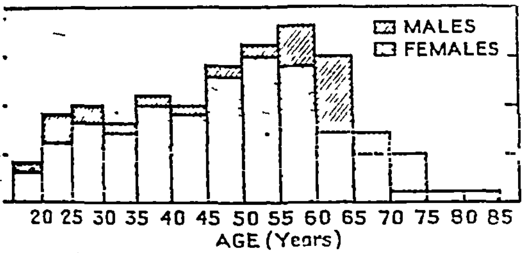
After five years 10 patients were untraced but alive a well when last seen, and of the 40 traced all were al and well.

After ten years, of 10 patients who had undergo operation ten or more years previously, 1 was untrace Of the 9 patients traced, 1 had died of cancer after seve years, 1 was alive and well after treatment to a secon primary neoplasm in the ninth postoperative yea and 7 were alive and well.

Other Forms of Thyroid Carcinoma (24 Cases)

After five years 4 patients were untraced, of who 3 had probably died of carcinoma, 12 were alive and wel 1 was alive after removal of recurrence, and 7 had die of cancer.

After ten years, of 11 patients who had undergone operation ten or more years previously 1 was untraced.



e-incidence of all types of malignant disease of thyroid gland.

e alive and well, 1 had died of intercurrent disease e eighth postoperative year, 1 was alive after treat- of a recurrence in the second postoperative year, had died of cancer.

AGE-INCIDENCE

many writers have emphasised, the age of the nt or the duration of symptoms gives no guarantee a thyroid nodule is benign. Lahey et al. (1940) cite the e case of a girl, aged 20, with a small thyroid adenoma h had been present for three years, who died of brain stases after partial thyroidectomy and postoperative iation to the extent of 7000 r. Pemberton and llace (1941) state that malignant thyroid disease is ively common in younger patients, and 22% of cases of carcinoma of the thyroid occurred in nts under the age of 20.

e age-incidence of all forms of thyroid carcinoma ur series is shown in the accompanying figure. In case of the youngest patient symptoms had been noted at the age of 3 years, and in the whole Royal Hospital series for 1931–38 27% of patients with oid carcinoma were under the age of 30 when ted, but the relatively small number of cases renders lusions risky. In all forms of thyroid carcinoma verage age at operation was 42·7 years, with extremes and 83 years, and the average duration of symptoms been 6·98 years, with extremes of 39 years and 5 s for malignant adenoma and 4 years and 1 week ther forms of carcinoma. Only 34·6% of the patients complained of an increase in size of the lump, and any of these the increase had been very gradual.

TREATMENT

he general lines on which the patients in this series e treated are as follows.

peration.—If a localised nodule was present, it was oved by the usual method of resection-enucleation. he presence of several nodules made wider resection isable, the affected lobe was excised to remove all affected tissue. If the appearance or consistence of tumour when exposed at operation suggested carci- na, the affected area was resected, as wide a margin healthy tissue as possible being removed. If any cent tissue was adherent or infiltrated, as wide block removal" as possible was done.

ostoperative Irradiation.—All the patients received toperative irradiation, but dosage varied widely. e early cases, from the 1920s until the middle 1930s d several series of treatments with small doses, but er 1935 one series was usually given, starting with fairly low dose but sometimes being stepped up to 00 r, the usual dose being 2500–3000 r. A more detailed cription of radiotherapeutic measures has been given Graham and McWhirter (1947).

RECURRENCY

Recurrent nodules should be even more suspect. In e present series there were 7 cases of recurrent nodules; 3 of these proved (at the second operation) to be frankly carcinomatous though originally either innocent or of the malignant adenoma type. Three interesting cases will be described in more detail.

Case 1.—A woman, aged 27, developed a small adenoma in the right lobe of her thyroid. This was removed by enucleation-resection and found to be a malignant adenoma. She remained well for ten years and then noted another swelling in the left lobe of her thyroid. This was removed by enucleation-resection, and the pathological report was: "A single adenoma composed of columns and solid masses of anaplastic cells. There are many thin-walled vessels, some containing cells in their lumina. Histologically, a malignant adenoma, which corresponds to descriptions of earlier adenoma."

Case 2.—A woman, aged 41, had a seven-eighth partial thyroidectomy for generalised nodular goitre, and histological examination revealed a papillary adenocarcinoma in one area. Deep X-ray therapy was given postoperatively and the patient remained well for eight years. She then began to notice breathlessness on exertion, lassitude, and some loss of weight; when seen two years later she had no toxic signs, but there was a firm nodule about $^1/_4$ in. in diameter in the region of the thyroid cartilage on the right side. The nodule did not seem to be attached to deeper structures, but after a few weeks' observation it was decided that exploration was advisable.

At operation an oval mass of abnormal thyroid tissue about an inch long was found adherent to the carotid sheath, trachea, and sternohyoid muscles. It was removed, and the pathological report reads: "Multiple small adenomata both colloid and fœtal; one edge shows invasion by carcinoma cells. One subgroup bears some resemblance to adenoma of eleven years ago, but remainder shows little differentiation. The original carcinoma seems to have recurred."

Case 3.—A girl, aged 14, was first seen in December, 1934, when partial thyroidectomy was done, and section of the specimen showed papilliferous adenocarcinoma. In January, 1935, the patient received a routine course of radiotherapy. In January, 1936, she reported with enlarged cervical lymph-nodes. These were excised, and further nodes were excised in April of the same year. On each occasion the excised masses consisted of lymph-nodes invaded by adenocarcinoma. In April she had a further course of irradiation, but by July further enlarged nodes were present. These were excised and on section showed "much infiltration of surrounding tissue and invasion of veins." Two more courses of irradiation were given in August and September, 1936. After this the patient was seen at regular intervals with no evidence of recurrence. In May, 1945, nine years after the last treatment, a soft rounded mass was noted in the thyroid region. In January, 1946, it grew bigger and was excised. On section the mass showed features of both malignant adenoma and carcinoma. In May, 1946, the patient was admitted for excision of a further nodule in front of the trachea; this was found at operation to extend down behind the suprasternal notch, and section showed that it was a papillary adenocarcinoma. In December, 1948, a further nodule was excised, from the left side of the trachea, and this again proved to be an adenocarcinoma on section. In March, 1949, a further nodule was found, in front of the trachea and proved at operation to be a recurrence in the pyramidal lobe.

The third case is remarkable for the long survival despite repeated local recurrences—fourteen years since the first operation—particularly in view of the patient's youth when first seen.

These 3 cases show the necessity for long-continued postoperative supervision, and the dangers of drawing conclusions from the results in cases less than five years after treatment.

CONCLUSION

It is agreed by those with wide experience of thyroid carcinoma that all non-toxic nodular goitres should be removed surgically, but it may require a good deal of moral courage on the part of the general practitioner to persuade a patient with a small nodule in the thyroid gland, which may have been present many months without causing symptoms, to submit to operation.

It is hoped that the arguments propounded here will provide sufficient inducement to this desirable end.

We wish to thank the staffs of the Royal Cancer and Royal Free Hospitals for permission to use the hospital records; Prof. D. W. Smithers for his encouragement and advice; and Dr. H. O. Hartley for helpful criticism.

STREPTOMYCIN IN THE TREATMENT OF TUBERCULOUS SINUSES

REVIEW OF 11 CASES

R. HARVARD DAVIS
B.A., B.M. Oxfd
JUNIOR RESIDENT MEDICAL OFFICER, THE NORTH WALES SANATORIUM

THE results of treatment of tuberculous cutaneous sinuses with streptomycin at the North Wales Sanatorium since September, 1948, have been so dramatic that this early review seems justified.

The pronounced effect of systemic streptomycin on tuberculous sinuses has been reported by several workers (Hinshaw et al. 1946, American Trudeau Society 1947, Feldman and Hinshaw 1948). Brock (1948) reviews 12 cases with a total of 60 draining sinuses. He used a dosage of 1·8 g. daily, divided into six doses given every four hours, for 90–150 days, with an interval in the longer courses; in 10 cases the sinuses originated in bone, 1 sinus was ischiorectal, and 1 developed after laparotomy. The average duration of the sinuses before treatment was two years. Only 1 sinus remained patent after four months, and most of them closed within twelve weeks of the start of treatment.

The present review is of 11 cases with 28 draining sinuses; in 5 cases the sinuses originated in bone and joint, in 3 cases they developed in thoracoplasty wounds, in 2 cases they followed nephrectomy, and in 1 case Monaldi drainage. The dosage of streptomycin adopted was usually 1 g. daily, but in some acute cases 0·75 g. was given twice daily; the total dose depended on the response, and no local treatment with streptomycin was attempted. In all the 8 proved tuberculous cases the tubercle bacillus was of the human type.

THERAPEUTIC EFFECTS

General.—One of the most conspicuous features in all the cases was the exceptional improvement in the patient's general condition, which was subsequently maintained; in cases 7, 9, 10, and 11 (see table) the response was such that, owing to the extreme sinus cachexia, streptomycin therapy was a life-saving measure. The control of the toxæmia was reflected in the temperature chart; in most cases the temperature settled within three or four weeks of the start of treatment. An improved appetite was a notable feature of all cases, and the few patients who were weighed regularly showed a definite increase of weight during and after treatment.

Local.—A favourable local response to streptomycin was shown by the discharge from the sinus becoming serous instead of purulent and diminishing in quantity. This occurred within three or four weeks of the start of streptomycin therapy and was followed by the development of healthy granulation tissue, a scab, and finally a firm healthy scar. A similar observation was by the American Trudeau Society (1947), F Hinshaw (1948), and Brock (1948). In the present 74% of the sinuses healed within three months, further 25% after three months; and the single remaining open looks much healthier. No reopened. One required plastic surgery owing to The time taken by the sinuses to close was as

ANALYSIS OF CASES

Time taken	*No of sinuses*
One month	2 (*7·1%*)
Six weeks	8 (*28 6%*)
Two months	2 (*7·1%*)
Three months	8 (*28 6%*)
More than three months	7 (*25%*)
Remained open	1 (*3 6%*)

The average duration before treatment was ab 11½ months, and the average length of time since clo is 3 months 3 days, the longest being 7 months 15 day

Other Lesions.—No change was observed in pulmo lesions, and only one case of early joint (case 7) showed a striking improvement (see

Complications.—There was some discomfort at of injection in most cases, but it was never Cases 3, 5, and 7 had some transient giddiness in the few weeks, but the dosage was not reduced, permanent vestibular damage was apparent. Case 7 a mild urticarial rash on the face on the fiftieth d but it subsided rapidly when 'Benadryl' was giv These complications were less than had been expec from earlier reports and confirm the observation th if the dosage is kept below 2 g. daily, complicati are considerably reduced (Medical Research Cou 1948).

DISCUSSION

Sinuses may be arbitrarily divided into three m groups: (1) those, usually multiple, which give rise extreme cachexia and are usually associated with spreading lesion; (2) those, usually single, which or may not give rise to much cachexia and are usu associated with a localised lesion which is not spreadin and (3) the chronic sinus which may persist for ye after the underlying lesion has healed and which compatible with a healthy active life. These are pro ably caused by tuberculous infection of the surroundi soft tissues (Hawkins and Thomas 1946) and shou respond well to streptomycin.

Ten years ago almost all the patients in group 1 a some in group 2 died, the treatment, which was usu ineffective, consisting of such measures as ultravio irradiation. Secondary infection was an extreme serious complication in all these groups, leading amyloid disease in many cases. With the use of sulphonamides and penicillin the dangers of second infection were reduced, but even then 5% of pati with combined skeletal and pulmonary disease died sinus cachexia (Hawkins and Thomas 1946).

The present series shows that 93% of a varied collec of sinuses closed within four months of the start streptomycin therapy, and that streptomycin had a m pronounced effect in controlling sinus cachexia. Th prognosis of sinus cases is therefore improved with th form of therapy, and the following conclusions may b drawn.

Sinuses Originating in Bone and Joint Tuberculosis

Of patients with bone and joint tuberculosis, 30% develop abscesses, of which 76% break down to form sinuses (Hawkins and Thomas 1946); this type of ca reacted dramatically to streptomycin. Both Girdlesto (1940) and Mercer (1944) emphasised that the progno in tuberculosis of bones and joints is materially worse a sinus forms and becomes secondarily infected. The defined the treatment of abscesses as primarily conserva and in their view the abscesses should not be aspi- . unless there is pressure on vital parts, extreme on of the skin, or secondary infection. In pyogenic tions with pus formation early drainage is an oted surgical principle. With the aid of streptomycin may now be applied to tuberculous abscesses, and ated aspirations with the attendant dangers of idary infection and possible ultimate sinus formation ld be discarded in favour of relatively early and ive drainage under cover of streptomycin. Feldman Hinshaw (1948) mentioned this in their earlier al reports, and both they and Brock (1948) laid on the tremendous importance of adequate drainage scesses if streptomycin is to have the desired effect. necessity for not only free but also early drainage is rated in the present series, the most striking results ıg been obtained in patients with recent severe activity.

ses Originating in Thoracoplasty Wounds

the past this type of sinus was very resistant to all s of treatment. This was probably because the sinus lly originates in a patent intrapleural or extrapleural , which is often infected with tubercle bacilli; and, this space is obliterated, the sinus cannot close. 4 illustrates that streptomycin will sterilise these es and so allow them to close either by approxi- on of the walls or by the formation of healthy nlation tissue.

ANALYSIS OF CASES

Type and duration of disease	Site of sinus and duration before treatment	Dosage of strepto-mycin and total given	Swab culture before treat-ment	Duration before closure (days)
Bilateral pulmon-ary 17 yr.	Rt. anterior chest, 4 mos.	1 g. daily, (47 g.)	+	33
Pulmon-ary, 2 yr.	(1) and (2) Pos-terior chest, 12 mos.	1 g. daily (131 g. in two courses of 47and 84 g.)	(1) and (2) +	(1) 169, (2) 178
Pulmon-ary, 8 yr.	(1), (2), and (3) Posterior chest, 25 mos.	0·75 g. b.d. (still in progress)	(1), (2), and (3) +	(1) 10, (2) 74, (3) 69
Bilateral pulmon-ary, 2 yr.	(1) and (2) Anterior chest, 3 days	0·5 g. b.d. (90 g.)	(1) and (2) +	(1) 75, (2) 20
Renal tract, 6 mos.	(1) and (2) Lt. nephrectomy wound, 3 days, (3) Scrotum, 2 mos.	1 g. daily (90 g.)	(1), (2), and (3)—	(1) 92, (2) 92, (3) 63
Rt. kidney	(1) Rt. groin, 5 mos. (2) Rt. loin, a few days	1 g. daily (still in progress)	(1) and (2) —	(1) 42, (2) 90
Spinal caries (L5), 18 mos.	(1) and (2) Rt. groin, 12 mos.	1 g. daily (90 g.)	(1) and (2) +	(1) 88, (2) 90
Spinal caries (L1, 2, 3), 18 mos.	(1) Lt. loin, 17 mos. (2) Rt. iliac fossa, 4 mos.	1 g. daily (90 g.)	(1) + (2) not done	(1) open, (2) 73
Spinal caries (L5)	(1) Rt. groin, 5 mos. (2) Rt. loin* (3) Lt. loin*	1 g. daily (90 g.)	(1), (2), and (3) +	(1) 99, (2) 99, (3) 200
Rt. hip, 22 mos.	(1) to (6) Rt. upper thigh, 1–12 mos.	1 g. daily (90 g.)	(1) to (6), none taken	(1) 137, (2) 137, (3) 100, (4) 64, (5) 69, (6) 66
Doubtful lesion of rt. sacro-iliac joint, 3 mos.	(1) Rt. iliac fossa (fæcal fistula), 4–12 mos. (2) Lt. loin, 2 days	1 g. daily (90 g.)	(1) and (2) +	(1) 63, (2) 63

Formed a few days after streptomycin treatment was begun.

Secondary Infection with Pyogenic Organisms

Cairns (1949) found that culture plates exposed in the operation field during intracranial operations always yielded a bacterial growth despite the most rigid precautions, but such precautions can hardly be expected during the dressing of sinuses, and thus it is almost impossible to prevent secondary infection in every case. The present series shows that, where there is delayed healing or only little response to streptomycin, a swab often reveals secondary infection, and this possibility must always be borne in mind. The onset of secondary infection is accompanied in most cases by a change from the low-grade remittent fever of tuberculous toxæmia to the high intermittent fever characteristic of pyogenic infection.

The impression has been gained that penicillin-resistant staphylococci seem more common in tuberculosis than in other diseases. Continued treatment with sulphonamides and penicillin in such cases has given very satisfactory results. Case 11 shows that in the presence of a mixed infection with the tubercle bacillus and the *Bact. coli* group of organisms streptomycin alone can produce a dramatic response.

Effect on Bone and Joint Tuberculosis

Previous reports gave no hope that streptomycin had any effect on established bone or joint tuberculosis, and no effect was seen in 4 of the 5 cases treated in the present series, the skeletal disease being old-standing. In case 7, with tuberculosis of the fifth lumbar vertebra and multiple sinuses, a fresh lesion in the hip appeared while streptomycin therapy was in progress. For four months this lesion clinically improved rapidly, though without any material change in the radiological appearances. This improvement took place despite the fact that the patient could not tolerate adequate immobilisation, because of his extremely poor condition and the positions of his multiple discharging sinuses.

Length of Treatment

A ninety-day course of streptomycin therapy seems to be satisfactory in most cases, and the persistence of sinuses is no indication to continue longer, because some may still close. A second course may be given after a short rest if there is renewed sinus activity.

Streptomycin Sensitivity Test

Owing to the delay before the result of a laboratory test of sensitivity can be known, it seems to be of little clinical value unless a second course of streptomycin seems necessary.

Significance of Swabs

In the choice of cases for streptomycin therapy it has been found that the inability to recover tubercle bacilli is no reason to withhold streptomycin if, from the history and the appearance of the granulations, the sinus is obviously tuberculous. As previously pointed out, the more active the sinus the better the response, and this is logical in view of the bacteriostatic action of streptomycin and is supported by the fact that in some of the present cases a negative swab was obtained immediately before the sinus closed.

SUMMARY

Systemic streptomycin therapy has been given to 11 patients with 26 draining cutaneous tuberculous sinuses, which in 5 cases originated in bone and in 3 followed thoracoplasty, in 2 nephrectomy, and in 1 Monaldi drainage.

This treatment has a definite value for sinuses developing in thoracoplasty or abdominal wounds of tuberculous origin, and the response of sinuses originating in bone is dramatic.

A plea is made for the treatment of tuberculous abscesses by early drainage under streptomycin cover,

but further experience will be necessary to determine the best time for such drainage.

I am grateful to Dr. F. S. Hawkins, Dr. G. O. Thomas, and Mr. J. Howell Hughes, F.R.C.S., for their advice during the preparation of this paper.

GASTRIC SECRETION AND SUBSEQUENT DYSPEPSIA

A FOLLOW-UP STUDY[*]

RICHARD DOLL
M.D. Lond., M.R.C.P.
MEMBER OF MEDICAL RESEARCH COUNCIL'S STATISTICAL RESEARCH UNIT

F. AVERY JONES
M.D. Lond., F.R.C.P.
PHYSICIAN I/C GASTRO-ENTEROLOGICAL DEPARTMENT, CENTRAL MIDDLESEX HOSPITAL

N. F. MACLAGAN
M.D., D.Sc. Lond., M.R.C.P.
PROFESSOR OF CHEMICAL PATHOLOGY IN THE UNIVERSITY OF LONDON AT WESTMINSTER MEDICAL SCHOOL; CHEMICAL PATHOLOGIST, WESTMINSTER HOSPITAL, LONDON

FIFTEEN years ago Lander and Maclagan (1934) investigated the response of 100 normal medical students to histamine test-meals. The students were all healthy, any that had had gastro-intestinal symptoms having been excluded. They do not therefore provide a random sample from the point of view of determining the liability to develop ulcers, but they do provide an opportunity for determining whether there is an association between gastric secretion in health and the subsequent development of dyspepsia.

Records of 99 of the subjects are still available. Gastric secretion had been stimulated by an injection of 0·5 or 0·75 mg. of histamine,[†] and measurements had then been made of the highest free acidity and the volume of juice and amount of free acid secreted per hour.

The subsequent medical history has been obtained by a questionary. Three of the original 99 are known to have died, and the addresses of 10 others cannot be traced; 85 of the remaining 86 have answered the questionary.[‡]

One of us (F. A. J.), who had no knowledge of the results of the previous test-meals, has divided the subjects into four groups, as follows, according to the history given in reply to the questionary:

(1) No history of dyspepsia (45 cases).

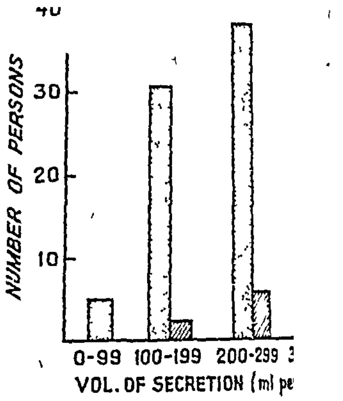
(2) History of minor dyspeptic symptoms—e.g., heartburn or belching (12 cases).

(3) History of significant abdominal pain not suggestive of ulcer—e.g., associated with diarrhœa, persisting continuously for several days, or occurring in isolated attacks (9 cases).

(4) History of dyspepsia suggestive of ulcer—i.e., attacks of epigastric pain related to meals and occurring in bouts (10 cases).

Group 4 contains 3 men in whom a peptic ulcer had been clinically diagnosed, but in no instance had an ulcer been proved radiologically or by operation.

The results of the original test-meals, averaged for each group, are shown in table I.



Volume of gastric juice and develo of subsequent symptoms: hatched co dyspepsia suggesting peptic ulcer; columns, other or no dyspepsia.

The groups are comparable as regards sex and age, all the subjects are men, and the average age of each group at the time of the test-meal was 21·8–22·8 years.

From table I it is evident that the highest free acidity attained was practically the same in all the groups. In contrast, the average volume of juice secreted by those who subsequently developed dyspepsia suggesti ulcer was significantly greater than that secrete the others. The difference in the average amou free acid secreted was almost significant and was evi more closely related to the volume of juice se than to the maximum acidity.

Similar results are obtained by an analysis of va applied to all four groups, when it can also be s that there were no significant differences among the non-ulcer-type groups.

The variation in the volumes of juice secret shown by the frequency distribution of the indi results, as follows:

Vol. of juice (ml. per hour)	*No. of men*	
	Ulcer-type dyspepsia	*Others*
0– 99	0	5
100–199	2	31
200–299	6	39
300 +	2	0

From this it will be seen that all the cases of dys suggestive of ulcer occurred in subjects who had se more than 100 ml. of gastric juice an hour (se accompanying figure).

DISCUSSION

Ryle and Bennett (1937) reported a similar inve tion. They followed up 120 men who had had test-meals 12–15 years previously, when in good g health and completely free from digestive sym Their results are summarised in table II.

Ryle and Bennett concluded that they could no any support for the view that hyperchlorhydria necessary precursor of the tendency to ulcer. material cannot be compared exactly with the p

[*] A communication to the British Society of Gastro-enterology.

[†] Eight received only 0·5 mg., but the results were not appreciably different from those when 0·75 mg. was given.

[‡] The 86th reply was received after the results were in print. It did not appreciably affect them.

since detailed figures were not given; in particular, ethod of performing the test-meals did not allow tes to be made of the volume of gastric juice d, the measurement found to be of the greatest t in the present investigation. It is particularly g that, in our series, none of the subjects with a on of less than 100 ml. an hour in response to ine developed symptoms suggestive of ulcer, is the only 2 who had a secretion of more than . an hour have done so.

e is general agreement that most patients with al ulcers show hyperacidity and hypersecretion, is in patients with gastric ulcers the figures are l or below average (Bockus 1943, Ihre 1939). uestion, however, arises whether hypersecretion ctor in the production of duodenal ulcers or is ult of the ulcer. Shay et al. (1942) have shown he normal mechanism by which gastric secretion ibited by the presence of free hydrochloric acid duodenum is depressed in patients with duodenal and they have suggested that the hypersecretion ndary to the ulcer instead of being its precursor. resent series is small, but the results are clear-cut, is reasonable to adduce them in favour of Hurst's that increased gastric secretion predisposes to the pment of ulcer-like symptoms, though whether al ulceration has not been determined.

.. Why is it so widely granted that the methods of ht and generalisation used in science do not reach to ems of value? I know nothing to suggest that the ion of value concepts is an activity which is fundaally different from that which goes into creating such pts as space, time, the physical universe, the organisation e nervous system, or the ecology of host and enzyme. . . . ce is concerned with function, with structure, with ion and with organisation. The concepts of value are imple, even when put beside these; and it is certainly bvious either that they are empty fictions, or that they od-given. It is surely time that we thought about their ion to scientific concepts less dogmatically and more ly."—J. BRONOWSKI, *New Statesman*, Nov. 19, p. 586.

ACUTE DISSEMINATED ENCEPHALOMYELITIS FOLLOWING HERPES ZOSTER, VACCINATION, AND IMMUNISATION

LIONEL WOLMAN
M.A., M.B. Camb., M.R.C.P.
SQUADRON-LEADER, ROYAL AIR FORCE; NEUROPSYCHIATRIST, PRINCESS MARY'S R.A.F. HOSPITAL, HALTON

MENINGO-ENCEPHALITIS sometimes complicates herpes zoster and more often follows smallpox vaccination; but meningo-encephalitis following both herpes zoster and vaccination is rare; apparently only 2 cases have been published.

Lillie (1943), who treated successfully 11 cases of herpes zoster ophthalmicus with smallpox vaccine, reported that his first case developed meningo-encephalitis ten months after vaccination. A purulent localised infection of the skin of the nose two weeks before the onset of nervous symptoms was considered to be the probable cause. Madonick's (1946) case of herpes zoster ophthalmicus, treated by vaccination four days after the onset of the rash, developed meningo-encephalitis eight days later. Both of these patients recovered.

The following case is unusual in that the herpes zoster had healed before routine vaccination was done. The subsequent development of the nervous symptoms made the correct diagnosis problematical.

CASE-RECORD

A corporal, aged 39, who had served as a cook in the R.A.F. for the past eight years, had been vaccinated successfully and without ill effect for the first time in November, 1942, at the age of 32. An unsuccessful attempt had been made at revaccination in May, 1945. The patient's previous inoculations had included T.A.B. 0·5 ml. and A.T.T. 1 ml. in August, 1941, and T.A.B.T. 0·5 ml. each subsequent year till 1944. He had also been immunised against diphtheria by two inoculations in February, 1942, and against scarlet fever by five weekly injections at the same time. In childhood he had had measles, mumps, rubella, and influenza, but never varicella or whooping-cough. There was nothing else of note in his previous medical history till the onset of the present trouble.

On Feb. 20, 1949, he developed left-sided frontal headache. Vesicles appeared next day on the left upper eyelid and spread to the left side of the forehead two days later. Apart from the headache, which was severe at the onset, there was little constitutional disturbance, and the patient returned to duty after a week. Though at the onset it was feared that the conjunctiva might be affected it escaped involvement, and this attack of herpes zoster ophthalmicus subsided within a fortnight, leaving scars on the forehead.

Since the patient was due to go overseas and had recovered from the herpes zoster, he was vaccinated for the third time and injected with T.A.B.C. 0·25 ml. and A.T.T. 1 ml. on March 7. After these procedures he experienced no ill effects. The vaccination produced the reaction of immunity, with slight redness of the arm three days later, but this rapidly subsided.

The patient was perfectly well till twelve days later, when he woke up at 4 A.M. on March 19 feeling ill with headache nausea, dizziness, and a feeling of rotating to the left. He vomited four times in the next six hours. After about three hours the dizziness, which had not been associated with tinnitus or deafness, cleared, leaving him exhausted. He then noted diplopia for distant objects; and, when he tried to get up, his left leg gave way under him. He tended to stagger to the left and when he tried to save himself he found his left arm weak and clumsy. On using his hands he noted pronounced shakiness of the left hand.

On examination the patient was febrile, with a temperature of 101°F. There was a coarse nystagmus when he looked to the right and to the left. The optic discs were normal, and the ocular movements appeared full. The lower jaw showed a spontaneous sustained side-to-side movement at the rate of 80 a minute; this disappeared on voluntary effort. There was a left-sided weakness of the muscles supplied by the trigeminal nerve, but cutaneous sensation was unimpaired. All the other cranial nerves were normal. Hypotonia of both arms and legs was present, more pronounced on the left side.

The left arm and leg were weak in all movements, as were plantar flexion and dorsiflexion of the right foot. No fibrillation or wasting was seen. There was gross ataxia of the left arm and leg, with difficulty in performing rapid small movements with these limbs, but no past pointing. All sensations were normal. Reflexes were normal, except the right knee-jerk, and both ankle-jerks were unobtainable. The right plantar response was flexor, and the left equivocal. With the eyes closed the patient immediately lost his balance. Other systems were normal, apart from a slightly raised blood-pressure of 170/90 mm. Hg.

Investigations.—Lumbar puncture on March 26 yielded a clear colourless fluid under a pressure of 100 mm. H_2O, with no evidence of spinal block. The cerebrospinal fluid (C.S.F.) contained 14 lymphocytes per c.mm., 85 mg. of protein per 100 ml., and a slight excess of globulin with the Pandy reaction. It produced no alteration in the colloidal gold curve and gave a negative Wassermann reaction. The blood Wassermann and Kahn reactions were negative. A blood-count and the erythrocyte-sedimentation rate were normal. Audiometry and caloric tests were made but were normal; and so was an electromyogram of the muscles of the arms and legs.

Progress.—The patient slowly improved. His temperature settled within 48 hours. The headache, which was mainly left frontal over the site of the herpes scars, persisted about two weeks and then cleared, by which time the diplopia had disappeared. He began to get up a week later, and, though his left leg gave way at first and was sometimes uncontrollable owing to the ataxia, he could get about with a stick. Within five weeks of the onset of the illness he could walk normally and the clumsiness of the left hand was only slight. About this time the side-to-side movement of the jaw, which had gradually diminished, disappeared. Six weeks after his illness began the patient was fit to be transferred to a rehabilitation unit. The cranial nerves were then all normal, apart from slight weakness of the left masseter muscle; there was slight cerebellar ataxia of the left arm and leg, with some hypotonia; and the right knee-jerk and both ankle-jerks were still absent. The patient returned to duty on July 11.

C.S.F. Changes.—The C.S.F. was examined twice more, at three-week intervals after the onset of nervous symptoms. The findings were as follows:

	After 3 weeks	*After 6 weeks*
Cells (lymphocytes) per c.mm.	11	4
Protein, mg. per 100 ml.	65	35
Globulin	In excess	No excess
Lange gold curve	0012344432	0001210000
Wassermann reaction	Negative	Negative

DISCUSSION

Though this patient appears to have had an acute disseminated encephalomyelitis, from which he has made an excellent recovery, the ætiological agent is not at all certain. At least four possible explanations for the facts can be offered.

(1) The events in the history might all be unconnected. The patient first had an attack of herpes which settled; he was then vaccinated and immunised; finally he had an attack of a demyelinating disease, such as disseminated sclerosis. Apart from the natural desire to bring the events together under one heading, it seems most unlikely that the earlier presence of either the herpes zoster or vaccinia virus had nothing to do with the subsequent symptoms, especially since both are known to produce encephalitis. There was no previous history of any transient episode typical of disseminated sclerosis, and though only the continued observation of the case can eliminate this possibility with certainty, it seems the least likely explanation from the physical signs elicited.

(2) The nervous symptoms may have been due to a herpes-zoster encephalitis, which came on four weeks after the beginning of the cutaneous eruption. In the reported cases the interval between the cutaneous and nervous manifestations varied from none (McCormick 1947) to six weeks (Thalhimer 1924). Thus Krumholz nd Luhan (1945), summarising the interval in 7 published cases, found it to be from four to six weeks in 3 ases in which the clinical manifestations were generalised, nd from one to three weeks in 4 cases where the onset vas with focal signs, such as facial palsy. The interval of four weeks in the present case thus fits in zoster encephalitis, while the fact that the physical were in face, arm, and leg on the same side as the rash, with the motor division of the trigeminal especially involved, supports this diagnosis. A point, emphasised by Schiff and Brain (1930), frequency of myoclonus in zoster encephalitis, and side-to-side movements of the jaw in the present presumably due to involvement of the olivode system, is an example of rhythmical myoclonus. tremors of the lower jaw were noted from time to in the case reported by Madonick (1946) after zoste vaccination. Against the present case being herpes zoster are the low cellular response in the and the rapid return to normality within six w since most of the published cases had a high and persi cell-count.

(3) The third possibility is postvaccinal encepha The onset of the symptoms twelve days after is consistent with this (Glanzmann 1927), as are the C.S.F. changes and quick return to normality. extremely rare, however, for encephalitis to de after a revaccination; according to Dutch exper this occurs in not more than 1 in 50,000 cases. It is less likely to occur after a third vaccination, espe when, as in the present case, the vaccination fails the case reported by Madonick (1946) the patient been vaccinated three times, and this was used as a against a diagnosis of postvaccinal encephalitis. Us in revaccination cases the incubation period is sh than the commonly accepted twelve days after pri vaccination, though there are examples of longer pe in published cases up to thirty-four days (Eckstein For these reasons it seems unlikely that postvac encephalitis is the correct diagnosis.

(4) The remaining possibility is that more than agent was responsible. In Lillie's (1943) case the period before symptoms developed in the nervous sys —the complication of nasal skin infection, and the ab of C.S.F. findings make it impossible to decide what the ætiological agent, but the explanation favoured Madonick (1946) in his case was that the zoster was activated by the second virus introduced by vac tion. This may apply in the present case; the pa genesis might then resemble that in the experiment rabbits by Levaditi and Nicolau (1926) and Zuruka (1927), in which herpes virus placed on the nasal mu or injected subcutaneously was induced, by simultan inoculation of smallpox vaccine, to excite a fatal herp encephalitis. The present case differs from Madon in that vaccination was performed later—fifteen instead of four—when the zoster had subsided instea being at its peak, and the C.S.F. ex changes were less and subsided more quickly. The explanation therefore be different.

A further suggestion is that m yelinoclasis from allergy due to an anti-brain ol. antibody Within a fortnight two viruses, (m herpes zoster vaccinia, and several foreign proteins, ho including and paratyphoid vaccine and tetan us toxoid, introduced into this patient. The pr oteins may h acted as an adjuvant to the viruses, or p ossibly vice ve This case might thus resemble, in the hu man, the exp ments on demyelination in the monkey by Rivers et (1933) and Rivers and Schwentker (1 935), confirm by Ferraro and Jervis (1940). Aqueous emulsions alcohol-ether extracts of sterile normal rabbit br were injected into monkeys and resulted in demyelinat in 7 out of 8 animals; but they did not do this wh combined with vaccine virus in monk ays previou sensitised to normal rabbit brain. In the rabbit, Le (1933) found that fresh homologous brain ti ssue posse little or no antigenic power, whereas Sc hwentker a Rivers (1934), using autolysed brain tissu ie or emulsio

n 0 1 ± ±5 ±5 ±5 grou 0·70 0·01 0·05

h homologous brain infected with vaccine virus, ble to produce antigenic activity as shown by :ation or complement-fixation.

adjuvant technique, whereby antigenic activity ianced by injecting material such as killed tubercle or liquid petrolatum in addition to the antigen, roduced by Freund and McDermott (1942) and en used successfully to produce demyelination. organ (1946) was successful in 7 out of 12 monkeys omologous spinal cord tissue as antigen, and in f 9 with cord infected with poliomyelitis; and et al. (1946) produced rapid demyelination in nonkeys by this technique. In the rabbit, instead ig to administer intracerebral injections of protein ously sensitised animals, as described by Davidoff 932), demyelination can also be produced by this ue (Morrison 1947). Thus, in laboratory animals iin antibodies can be produced by homologous altered by autolysis or made effective by the 1 of adjuvant.

e present case the processes involved may be along lines, with the possibility of auto-antigens being from the patient's own nervous system owing to fection. If this view is correct it might explain sence of features of both zoster and postvaccinal litis.

gh it is unfair to generalise from a particular case, on, if any, to be drawn from this report seems to there is a risk of myelinoclasis if either vaccina-immunisation is undertaken shortly after a virus n. In view of the frequency of these two proce-t seems worth while to inquire for any previous ifection, especially herpes zoster, and to delay ion if there has recently been one.

fourth possibility suggested is correct, immunisa-er an attack of herpes zoster is contra-indicated east 4–6 weeks—i.e., the incubation period of ncephalitis.

SUMMARY

e of acute disseminated encephalomyelitis occur-r weeks after an attack of ophthalmic herpes nd twelve days after combined vaccination and ation is described.

le ætiological factors are discussed, and it is d that foreign protein may act as an adjuvant iruses, thus relating the case to experiments on

e is a history of recent virus infection, especially zoster, it is suggested that vaccination or ation should be deferred because of the possibly l risk of encephalitis.

nks are due to the Director-General of Medical R.A.F., for permission to publish this case; Squadron-I. Meanock, who referred the case to me; Group-V. H. Tompkins for much useful advice and ment; Dr. P. H. Sandifer for helpful criticisms and ns; and Squadron-Leader J. M. White for help with

HÆMOLYTIC EFFECTS OF MYANESIN

D. R. T. CLENDON
B.A. Camb., M.R.C.S.
SENIOR ANÆSTHETIST

J. B. PENFOLD
M.B. Durh.
PATHOLOGIST

ESSEX COUNTY HOSPITAL, COLCHESTER

SINCE the introduction of 'Myanesin' by Mallinson (1947) and Berger and Bradley (1947) several objections have been raised to its use. The most serious of these is the possibility of its causing intravascular hæmolysis and hæmoglobinuria. Though much has been written on this subject, the issue is still confused.

Pugh and Enderby (1947) reported 3 cases of hæmoglobinuria following the intravenous injection of myanesin, and showed experimentally that the intravenous injection of 1·5 ml. of 10% or 5% myanesin in distilled water could produce intravascular hæmolysis. They deduced from their experiments that such hæmolysis occurs in all patients who receive intravenous myanesin, but that, owing to the high renal threshold for the excretion of hæmoglobin, hæmoglobinuria develops in only a few cases.

Lyall (1947) found hæmolysis in 44 of 50 cases in which myanesin had been used, but the hæmolysis was not serious, and there was no hæmoglobinuria.

Stephen and Chandy (1947) gave 30 mg. of myanesin per kg. of body-weight to 12 conscious patients, 10 of whom subsequently voided reddish-brown urine which gave a positive orthotoluidine test for blood but contained no red cells.

Hewer and Woolmer (1947) reported a case of fatal uræmia following an operation for which myanesin had been given. Hæmaturia had been noted on the fourth and fifth days after operation, and the patient died on the sixth day. The necropsy findings were similar to those in incompatible blood-transfusion, and it was suggested that death was due to renal anoxia following peripheral circulatory failure. A similar case was reported by Goodier and Goodhart (1949) in which complete anuria developed on the fourth day after the administration of myanesin; but this patient had also had 13·5 g. of sulphadimidine ('Sulphamezathine'). At necropsy the kidneys showed much cortical damage, in places amounting to necrosis.

Noble (1948) reported the case of a boy who received myanesin under anæsthesia and next morning passed 8 oz. of urine containing much free hæmoglobin, granular casts, and red cells. He was symptomless, and subsequent specimens of urine were normal.

Brooks et al. (1948) reported 2 cases in which intravenous myanesin was followed by intense hæmoglobinuria. They injected myanesin intra-arterially into a paralysed but otherwise healthy arm about to be amputated, and tested venous blood before and after injection of myanesin. They found gross hæmolysis in all four samples taken after injection but none in the pre-injection sample.

Wilson and Gordon (1948) reported a series of 60 cases of appendicectomy in children given intravenous myanesin. They found no hæmolysis before induction; slight hæmolysis and a slight increase in red-cell fragility after induction; and a considerable increase in hæmolysis and in red-cell fragility after myanesin. They found no hæmoglobinuria by naked eye or spectroscopically.

Ogilvie et al. (1948) showed conclusively that myanesin had a strong hæmolytic action in vitro.

Cowen (1948) reported a case in which an intravenous dose of myanesin, followed two days later by another dose produced no urinary change, but a larger dose, given a day later still, was followed in $1^1/_2$ hours by the passage of wine-red urine containing blood pigment and one or two red cells per field. The urine was not examined spectroscopically, and two hours later was normal.

Griffith et al. (1949) stated that of 75 conscious patients given myanesin 12 subsequently had transient hæmoglobinuria.

Davison et al. (1949) treated 2 cases of tetanus with myanesin: the first patient, in whom hæmoglobinuria was not observed, received 58 ml. in 60 hours; the second patient received 265 ml. in $26^1/_2$ hours, developed hæmoglobinuria, and died two hours later. At necropsy the kidneys appeared normal to the naked eye and on section. The serum showed "little or no hæmoglobin" microscopically, but the bladder contained slightly smoky urine.

Mallinson (1948) reported that out of more than 100 cases in which myanesin had been used he had found 3 possible examples of hæmoglobinuria, but incomplete investigation did not allow of definite conclusions. In 15 other cases of his, the urine was investigated: 5 gave a positive or weak positive benzidine test for blood, 4 contained a few red cells, and 4 contained a few casts, but no iron was detected spectroscopically in any of the specimens. Mallinson brought forward evidence that myanesin increased the fragility of the red cells, and suggested that, owing to this fact, the hæmolysis obtained by Pugh and Enderby (1947) in vitro was an artefact. He also pointed out (Mallinson 1949) that fatal anuria similar to that ascribed to myanesin can occur after operations in which myanesin has not been used.

Belfrage (1947) reported that a patient with tetanus who received 78 mg. of myanesin intramuscularly in 120 hours had a diminished renal output but showed no clinical evidence of hæmolysis.

Torrens et al. (1948) did not note hæmoglobinuria or signs of hæmolysis in a tetanus patient who received 7 g. of myanesin intravenously and 15 g. intramuscularly in nine days.

Ballantine (1948) reported 76 cases in which myanesin was used but did not mention hæmolysis or hæmoglobinuria.

Musgrove (1948) reported that in 200 cases given myanesin no naked-eye hæmoglobinuria was noted.

Schlesinger et al. (1948) stated that in a large series of persons "given 2% myanesin at the rate of 30 drops a minute" no hæmoglobinuria was produced.

We report here some clinical experiments made in an attempt to clarify the situation.

CLINICAL EXPERIMENTS

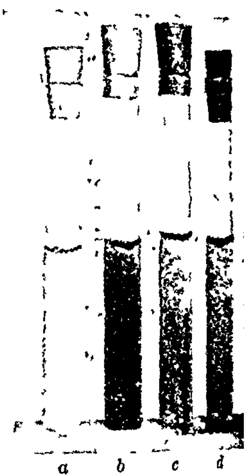
Twenty anæsthetised patients were given 1 g. myanesin dissolved in 10 ml. of solvent, as usually supplied by the makers. The myanesin solution was given intravenously at the rate of 1 ml. in 6 seconds. The premedication used was 'Omnopon' gr. $^1/_3$ and scopolamine gr. $^1/_{150}$. The anæsthetics administered, by the semi-closed method, were: (1) nitrous oxide and trichlorethylene; (2) nitrous oxide and ether; and (3) thiopentone, nitrous oxide, and trichlorethylene. The patients were all good surgical risks, all were adults, and no difficulties were met with in induction and maintenance of anæsthesia.

Four venous blood samples were taken from each patient: (1) after induction of anæsthesia but just before the injection of myanesin; (2) 10 minutes after the injection of myanesin; (3) 30 minutes after the injection; and (4) 60 minutes after the injection.

To obviate the danger of producing hæmolysis by the use of syringes, all samples were collected through a wide-bore needle with a small rubber tube attached to the hub. After the needle had been introduced, the blood was collected by gravity into clean dry bottles, which were allowed to stand until the sera separated. After the return of these patients to the ward, the first three specimens of urine voided were collected and sent to the laboratory.

As controls 10 other patients, who had received similar premedication and anæsthesia but no myanesin, were bled in a like manner and had their first three postoperative specimens of urine collected.

Blood (Hb 100–110% Haldane) was collected from one of us (J. B. P.) and heparinised with 10 I.U. per ml.; 10 ml. of this blood was then added to 90 ml. of water, producing complete hæmolysis. From this 10% solution of hæmolysed blood, standards were made as follows: 5%, 4%, 3%, 2·5%, 2%, 1·75%, 1·5%, 1·25%, 1%, 0·9%, 0·8%, 0·7%, 0·6%, 0·5%, 0·4%, 0·3%, 0·2%, and 0·1%. The sera obtained from the patients were matched with these standard tubes and a tube of unhæmolysed serum. Excellent comparison was obtained between test and standard samples, but it was sometimes difficult to express the degree of hæmolysis to the nearest 0·1%. The standard tube containing 0·1% of hæmolysed blood was just visibly pink, and any serum giving a reading less than this was considered to show no hæmolysis.



Four specimens of serum fro patient given myanesin: a, b injection of myanesin; b, 10 after injection; c, 30 minutes injection; d, 60

The specimens of urine from the 20 test patients and the 10 controls were examined for albumin, occult blood by the benzidine test, and microscopically for red cells and casts.

To estimate the delicacy of the benzidine test, hæmolysed blood (Hb 14·5 g. per 100 ml.) was added to normal urine in various proportions and subjected to the test. It was found that 14·5 mg. of Hb per 100 ml. of urine (≅0·1% of hæmolysed blood) gave a negative result, 29 mg. of Hb per 100 ml. a weak positive, and 58 Hb per 100 ml. a full positive reaction.

RESULTS

Hæmolysis.—None of the sera from the 10 pati who had not received myanesin showed any hæmoly nor did any of the samples taken from the 20 myan patients before the myanesin was given. After injection of myanesin, the sera of 18 of the 20 pati showed hæmolysis, and 2 did not. The amount of hæ lysis ranged from 2·75 to 0 2%. Usually the grea hæmolysis was obtained in the sera taken 10 min after the myanesin. (The figures for intravas hæmolysis speak for themselves.)

Urine.—The results were as follows:

	Myanesin patients (20)		*Controls* (10)	
	Positive	*Negative*	*Positive*	*Neg*
Occult blood	5	15	0	10
Red cells	4	16	0	1
Casts	18	2	3	7
Albumin (more than trace)	16	4	4	[illegible]

Of the 5 myanesin cases which had positive tests occult blood, 2 also showed red cells and casts, an casts only. All specimens of urine which gave a pos test for occult blood were turbid and browner than us Two of the 4 myanesin patients whose urines showed cells also had casts and gave a positive test for oc blood, whereas the other 2 had casts only. The diffe between the myanesin patients and the contr regards casts is highly significant, and as regards alb significant. The figures regarding occult blood and cells are not significant but are suggestive of a differe between the test and control series.

DISCUSSION

We have shown that the intravenous injection of 1 of myanesin is followed by hæmolysis in 18 out of cases. To meet the argument that this is an artefact, took all precautions to minimise trauma to the red c We did no fragility tests after myanesin, because believe that this test, which measures the o pressures in the cells in vitro, does not nece measure the fragility of the cells in their nor surroundings. The amount of trauma to which red cells were subjected in our experiments probably less than red cells experience in the body. 15 of the 18 cases showing hæmolysis this reach

aximum in 10 minutes. The evidence that some
ascular hæmolysis occurs after the clinical use of
esin is overwhelming; the real point at issue is
ler it is of sufficient degree to limit the usefulness
drug. We have not found any report of an investiga-
which correlates the degree of intravascular hæmo-
with its toxic effects: and, until more is known
this matter, it seems wisest to keep such hæmolysis
to a minimum. Our impression is that serious
s of hæmolysis are most likely to occur with the
doses of myanesin. Intravascular hæmolysis such
y follow incompatible blood-transfusion can cause
and death. Cases have been reported in which
esin was given and the patients subsequently
ped anuria, but it is still uncertain whether the
esin was to blame, because similar cases have been
ed where no myanesin had been given. Further
igations, particularly when symptoms arise, should
de and reported.

vious workers have tried to estimate the threshold
hich hæmoglobin is excreted by the kidneys.
avasquez (1940) placed the threshold between 459
82 mg. of Hb. per 100 ml. of plasma (equivalent to
3% of hæmolysed blood in a normal person). This
vorked out on a single case of paroxysmal hæmo-
uria with a urine pH of 5·5–6·3. Since none of our
its had such a high degree of hæmolysis and yet
had hæmoglobinuria, this figure for the threshold
rs to be too high. Gilligan et al. (1941), from experi-
in which hæmoglobin was injected into 10 normal
abnormal persons, concluded that the threshold
bout 135 mg. of Hb per 100 ml. of plasma. In our
of hæmoglobinuria the average maximum level of
the plasma was 202 mg. per 100 ml. of plasma,
as in those without hæmoglobinuria it was 142 mg.
presence or absence of hæmoglobinuria therefore
ly indicates the amount of intravascular hæmolysis.
possible dangers of intravascular hæmolysis, one
of which is myanesin, are anuria following renal
a, and permanent renal damage. The evidence that
esin can cause anuria is still controversial, and there
evidence that it can cause permanent renal damage,
e suggest that the drug should be used with great
n, avoiding unnecessarily large dosage and watching
th hæmolysis and hæmoglobinuria. Since the main
n seems to be borne by the kidney, myanesin
l not be given where renal function is impaired.

SUMMARY

vious work on the possibility of myanesin causing
ascular hæmolysis and hæmoglobinuria is reviewed.

sera and postoperative specimens of urine of 20
hetised patients receiving myanesin and 10 not
ing myanesin were examined.

molysis was present in 18 of the test cases, and in
of the controls.

differences in the *two* series were significant as
ls casts and albuminuria, and highly suggestive as
ls hæmoglobinuria and red cells.

is suggested that in the present state of our know-
of this drug it should be given in the smallest
ive dosage.

thanks are due to Dr. J. A. Fraser Roberts for his
st and advice.

HYPERSPLENISM WITH ARTHRITIS

REPORT OF A CASE

W. R. GAULD

M.D. Aberd., M.R.C.P.

ASSISTANT PHYSICIAN, ABERDEEN ROYAL INFIRMARY

HYPERSPLENISM was first described by Wiseman and Doan (1939, 1942), who reported as a new syndrome five cases of profound neutropenia of the peripheral blood, splenomegaly, and myeloid hyperplasia of the bone-marrow. None of these cases of splenic neutropenia (the name they gave to the syndrome) showed hepatic damage such as is found in Banti's disease, and there was a complete absence of factors known to cause agranulocytosis. In all these patients the leucocyte-counts became normal after splenectomy. Further examples of the condition have since been reported by Moore and Bierbaum (1939), Muether et al. (1941), Rogers and Hall (1945), Salzer et al. (1945), Langston et al. (1945), Kinsey and Bingham (1946), McClean and Coleman (1947), Sacks and Carey (1948), and Palumbo (1949).

In most of these patients the granular white cells were predominantly affected, but in some cases the platelets and/or red cells were also slightly reduced in number. Doan and Wright (1946) recorded two cases in detail and charted the blood findings in five others in which the numbers of white cells, red cells, and platelets (especially the last two) were all very low. This condition they termed splenic panhæmatopenia, and in every case splenectomy was followed by a rapid return of the blood picture to normal. Semple (1948) described a case which differed from those reported by Doan and Wright only in the slow recovery of the red-cell count after splenectomy.

All but one of these cases have been examples of acquired primary hypersplenism. The exception is one of the cases of splenic panhæmatopenia described by Doan and Wright (1946), which they believed to be congenital. Van Creveld (1948) reported such a condition in a child aged 2 years, and this, too, probably falls into the congenital category.

That hypersplenism may be secondary to a pre-existing enlargement of the spleen is generally recognised. Wilensky (1942), Mandelbaum et al. (1942), Dameshek and Miller (1946), Davis et al. (1949), and others have described examples of thrombocytopenic purpura complicating Gaucher's disease in which the symptoms were relieved by splenectomy. Doan and Wright (1946) mentioned three patients with Hodgkin's disease—one showing severe anæmia and neutropenia, and the other two thrombocytopenia with purpura—all of whose symptoms were relieved (the first for as long as 2 years) by splenectomy. They also cited two examples of a panhæmatopenic syndrome associated with Gaucher's disease, in both of which the symptoms improved after removal of the spleen.

The association of chronic arthritis, splenomegaly, and leucopenia in middle-aged people, first described by Felty (1924), is well known. Two of Wiseman and Doan's (1942) patients gave a history of joint pains, but manifestations of rheumatoid arthritis were negligible during the neutropenic phases. The patient described by Langston et al. (1945) also had arthritic symptoms, which cleared after splenectomy, leaving only the deformities resulting from the acute stage. Smith and McCabe (1948) published two cases of splenic neutropenia with arthritis; though their first patient had a hypoplastic marrow, both showed clinical improvement with a return to normal leucocyte-counts after splenectomy.

The following case is an additional example of hypersplenism with joint changes.

CASE-RECORD

A married woman, aged 38, was admitted to the Royal Infirmary, Aberdeen, on Dec. 8, 1947, with 9 months' history of tiredness, depression, loss of weight, and worry over domestic affairs. Her relations had noted her increasing pallor. She had had no dyspeptic symptoms except anorexia, and gave no history of breathlessness, cough, or unusual loss of blood. Since the birth of her first child in 1932 she had had a vesicovaginal fistula for which she had undergone four operations in that year without relief. During the past 16 years the fistula had remained unchanged, and the continual dribbling of urine caused much discomfort. About 1934 she had developed rheumatoid arthritis affecting mainly her hands. At first this was mild, but it gradually became more incapacitating, and in 1942 the patient had a course of chrysotherapy, the dosage of which is unknown. This treatment relieved her symptoms, and for the past 5 years her rheumatoid arthritis had been quiescent. The patient's family history was irrelevant.

On examination the patient was pale, tired-looking, and febrile, with some marginal atrophy of the tongue but no glossitis and no evidence of koilonychia. Her blood-pressure was 115/70 mm. Hg, and no abnormality was detected in her chest apart from a generalised soft systolic murmur, which was attributed to her anæmia. Her spleen was uniformly enlarged and extended to about 1 cm. below the umbilicus; it was firm, bulky, and smooth, but not tender. The liver was not palpable, and there were no enlarged cervical, axillary, or inguinal lymph-nodes. Detailed neurological examination was negative. There was only minimal evidence of rheumatoid arthritis, affecting particularly the second and third metacarpophalangeal joints on both sides. The urine contained no albumin or sugar, and microscopically showed nothing abnormal.

Investigations.—The initial blood-count was: Hb 52% (Haldane), red cells 3,421,000 per c.mm., colour-index 0·76, leucocytes 800 per c.mm. (neutrophil polymorphs 17%—non-segmented 12%, segmented 5%—lymphocytes 55%, and monocytes 28%), platelets 127,500 per c.mm. The red cells were microcytic and hypochromic. Serial leucocyte-counts, hæmoglobin, and platelet-counts are charted in the accompanying figure. Reticulocyte-counts were done from time to time but were always within normal limits. The icteric index was 5, and the plasma-protein level 8·22 g. per 100 ml. Stools were examined several times for occult blood with negative results. Blood-culture was sterile, and agglutinations against *S. typhi* (O and H), *S. paratyphi-B*, and *Br. abortus* were negative. The sternal marrow was examined on three occasions over a period of weeks. The following is a representative result: myeloblasts 4%, promyelocytes 9·7%, neutrophil myelocytes 26%, eosinophil myelocytes 1%, metamyelocytes 27·1%, polymorphs 2%, lymphocytes 9·3%, plasma cells 0·3%, hæmocytoblasts 0·3%, normoblasts 20·3%.

Radiography of the chest revealed no abnormality, and a barium swallow gave no radiological evidence of œsophageal varices.

Treatment.—Penicillin 20,000 units three obviously indicated to minimise the risk of in
the neutropenia. Iron was given in th
sulph., starting with gr. 3 t.d.s. but incr
later because of lack of response. Sinc
improvement, blood-transfusions were in

Progress.—Meanwhile the
deteriorating, the fever wa
the lumbar region, buttocks

ated and extensively inflamed as a result of the leakage of urine from the vesicovaginal fistula. T count remained almost constantly below 1000 per c the Hb and red-cell count varied directly with the of blood transfused. It was therefore decided to patient to splenectomy; but, as the final preparations being made, she developed a large carbuncle on the buttock. The operation had therefore to be delayed fo months, during which penicillin and small transfusio packed cells were continued. Eventually the carbuncle h and on March 16, 1948, after a transfusion of 1 pint of blood, the spleen was removed by Mr. Andrew Fowle accessory spleens were found at operation, and the liv normal in appearance and consistence.

Postoperative Progress.—The patient's convalescenc surprisingly smooth. The wound healed by first inte and the excoriated areas epithelised very quickly. (twelfth postoperative day, however, the patient devel left basal pneumonia; so penicillin, which had been st after the operation, was again given, and the pneu resolved within a week. Thereafter the patient im rapidly and was discharged to her home on May 4, 194

Follow-up.—Since that time the patient has been regular intervals. Her general condition has improved and she has regained all her lost weight. Her blood h invariably within normal limits and the most recent on Sept. 3, 1949, seventeen months after the ope showed Hb 110%, red cells 5,230,000 per c.mm., colour 1·05, leucocytes 9600 per c.mm. (neutrophil poly 60%—non-segmented 4%, segmented 56%—eosinophi lymphocytes 31%, monocytes 8%), and platelets per c.mm. In March, 1949, her rheumatoid arthritis fla The affected joints included the second metacarpopha on both sides, the left elbow, and both knees, but with therapy they have made satisfactory progress. In July the patient was successfully treated by her doctor in h home for pneumonia, and her chest is now clinical radiologically clear.

Pathology of Spleen (Dr. C. E. Lumsden).—The weighed 1450 g. Histologically there was nothing pat monic. The pulp was congested but showed no ab infiltration or fibrosis. The malpighian bodies, ho were enlarged owing to hyperplasia of the reticulum There was moderately severe hæmosiderosis, and th contained nuc lear detritus, but no erythrophagocyt leucophagocytosis was found.

DISCUSSION

aps the solution lies in a combination of these
ews—i.e., a splenic factor prevents maturation
affected elements, which as a result of their
rity are readily destroyed by the reticulo-
elial system in the spleen and elsewhere.

tion of Arthritis and Hypersplenism

he 5 cases reported by Felty (1924) all showed
erate leucopenia, but in no instance was it as
as in the 2 cases described by Wiseman and Doan
or in the present case, in all of whom, in further
listinction to Felty's cases, the rheumatoid
is was trivial during the neutropenic phases.
ointed out that his syndrome might well represent
disease with a coincidental arthritis, though he
d it was a distinct clinical entity. Hanrahan and
(1932) reported a case of Felty's syndrome in
the symptoms improved as a result of splenectomy
d out primarily to relieve the discomfort caused
plenic enlargement. The sternal marrow was not,
e, examined in their case, but the leucopenia was
vere than in Felty's cases and was of the same
s that found by Wiseman and Doan (1942).
s (1936), reporting a case of Felty's syndrome,
d that it was a primary blood disorder in which
turation of the granular cells was arrested.
of the bone-marrow at necropsy, however,
d diminished myeloid activity, and this case
e parallels more closely the first case reported
th and McCabe (1948). Steinberg (1942) noted
first time marrow hyperplasia in 2 cases of Felty's
ne and postulated that the spleen might be
ng the maturation of neutrophil cells. He held
f the marrow is not hyperplastic, splenectomy
not be done in these cases. Dameshek (1944)
d that Felty's syndrome was a form of splenic
enia brought about by splenic involvement in
ctious or toxic process of rheumatoid arthritis.

e present case there was a relapse of the arthritis
a year of splenectomy. The published follow-up periods of all the other cases have been very short, so the ultimate effect of splenectomy on the joint manifestations cannot be assessed. Symptomatically Felty's syndrome and hypersplenism are closely related, but it is difficult to be certain whether they have a similar ætiology, since the clinical information on the reported cases has often been inadequate. Time may show that the association of arthritis with hypersplenism is purely fortuitous, but at present it cannot be dismissed as such.

SUMMARY

A case of hypersplenism with rheumatoid arthritis is presented.

The ætiology of this condition and its association with Felty's syndrome are discussed.

I wish to thank Prof. H. W. Fullerton for permission to publish this case, and Dr. C. E. Lumsden for the pathological report on the spleen.

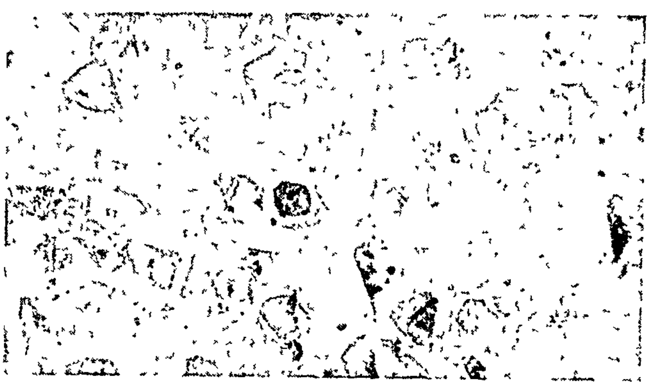
HYDROCOLPOS

N. C. SEN
M.B. Calcutta, D.G.O. Dubl., F.R.C.S.
OBSTETRICIAN AND GYNÆCOLOGIST, SANCTORIA HOSPITAL,
DISERGARH, INDIA

HYDROCOLPOS is a rare condition in which fluid other than blood has accumulated in a vagina occluded by an imperforate hymen, a retrohymenal membrane, or atresia. It is usually discovered either shortly after birth or just before puberty. Eleven cases have so far been reported, and eight of these belonged to the neonatal group.

Spencer (1916) described the first case; Mahoney and Chamberlain (1940) described four cases; and one case each has been described by Kereszturi (1940), Bowen (1941), Althoff (1941), Rosenblatt and Woolley (1943), Morris (1945), and Maliphant (1948). The age-incidence in these cases ranged from one day to eleven weeks in the neonatal group and from twelve to fourteen years in the prepubertal group, in which two girls had their normal periods five months after hydrocolpos was detected.

The fluid has been variously described, according to its naked-eye appearance. Thus it may be "turbid serous," "mucoid," "milky," and "chylous," perhaps depending on relative contributions of the various parts of the female genital tract (see below).



Smear of hydrocolpos fluid, showing desquamated vaginal epithelium in various stages of maturity, but no organisms. (Gram's stain.)

CASE-RECORD

An infant, aged 4 days, was admitted with intestinal obstruction due to imperforate anus and was operated on. During the operation it was noticed that the hymen was intact and bulged when the baby strained. Nothing was done at that time for this condition. The baby left the hospital on the 16th day, with advice that she should be brought back for dilatation of the anal canal.

On the 24th day she was readmitted, with excessive vomiting and scanty urine. She was dehydrated, with her skin inelastic and shrivelled. A fusiform swelling with a knob-like structure at its top was felt in the hypogastric region. The urinary bladder was emptied with a fine catheter, 4 ml. of urine being obtained. As the baby was crying at this time, the hymen was found to be bulging. The mass in the hypogastric region was still there. Rectal examination revealed a slightly fluctuant cystic mass in front, partly filling the pelvic cavity.

The hymen was punctured, about 32 ml. of milk-like white thick fluid was withdrawn from the vagina, and the swelling completely disappeared. The hymen was opened with a cruciate incision. The baby was treated for vomiting and left the hospital after a few days.

The fluid had a pH of 6·4. On standing for 24 hours, scanty clear supernatant fluid separated, and the deposit occupied about 98% of the total fluid. On staining, it was found to be full of desquamated vaginal epithelium in various stages of maturity (see figure) and containing various amounts of glycogen. Polymorphonuclear leucocytes were seen but no organisms were detected. The protein content of the fluid was 0·62%, but no fat-globules were seen. The fluid was sterile on culture.

DISCUSSION

Source of Fluid

Presumably every part of the female genital tract contributes to this fluid. Mahoney and Chamberlain (1940) described the morbid histology in this condition in necropsy and operation specimens. They found distinct evidence of activity in the uterine glands and the vaginal epithelium, which was thick and many-layered, keratinised, and loaded with glycogen. Similar activity of the female genital tract is not uncommon in the neonatal period, and slight bleeding or mucoid discharge per vaginam during the first two weeks of life is often met with in obstetric practice. Since in the present case the fluid was made up almost entirely of desquamated vaginal epithelium, whose pH was slightly on the acid side, the vagina seems to have contributed the most.

Pathogenesis

Both in utero and for about two weeks after birth (Dobszay 1938) the female child is under the influence of maternal œstrogens. The uterus and the cervix grow, and there is evidence of increased activity of the uterine and cervical glands during this period. The vagina assumes the adult type, and its epithelium becomes thick, keratinised, and loaded with glycogen. Its secretion becomes acid. Similar activity is also during the prepubertal period under the influ gonadal hormones secreted from the ovaries at thi It is precisely at these two age-periods that hydr is met with.

The fact that the fluid may vary is due to the u cervix, and vagina reacting differently accordi their states of sensitivity towards the hormones thus contributing different shares.

The endometrium has two functional part blood-vessels and its glands. These react independ to the œstrogens, but because they work simultane and usually uniformly their individuality is mask most cases. Sometimes one may act without other. Markee (1936), Daron (1936), Kaiser (1948 Bartelmez (cited by Markee 1936) have proved th vascular system of the endometrium is responsib menstrual bleeding, and where this system doe react to œstrogens there may not be any ble though the glands may react and secrete. Th nature of the discharge from the uterus depends reactivity of the individual parts of the endome towards gonadal hormones. Similar factors also dete the secretion from the cervix and changes in the v epithelium. According to the various proportio secretions from the uterus, the cervix, and the v the physical and chemical nature of hydrocolpos will vary. The fluid in the present case was aci it was sterile on culture and no organism was on staining. This is of interest because it show the presence of Döderlein's bacillus is not essent make the vaginal fluid acid.

Pathology

Besides the activity of the uterine and cervical and changes in the vagina and accumulation of fl it, the amount of which varies from 1 drachm to s ounces in neonatal period and from 0 85 to 2 27 in the prepubertal period, accumulation of fluid extend by regurgitation into the uterine cavity (1945)—a condition known as hydrometrocolpos.

The pressure of the fluid may cause stretching elongation of the urethra and the neck of the bla The bladder is pushed upwards and forwards. ureters may be obstructed at the ureterovesical jun and there may be bilateral hydronephrosis (Morris Kereszturi 1940). Infection may supervene on condition, causing pyelonephritis (Kereszturi 1940). colon may be displaced upwards, and there ma intestinal obstruction, sometimes due to an imperf anus caused by failure of the process of canali similar to atresia of the vagina or imperforate hymenal membrane or hymen. Pressure on the may cause œdema of the lower half of the (Morris 1945).

Clinical Features

Symptoms may be alarming within two days birth. Retention of urine was urgent in six out of e cases reported. "Abdominal tumour" was prese eight out of eleven cases, in five of which laparo was done to remove it. Intestinal obstruction was f in two children whose condition was serious, one of dying on the first day of life, and the other having ext pressure symptoms. Swelling at the vulva was sec one case and was due to a bulging hymen. Back and abdominal pain were met with in the prepub age-group.

Most of these conditions were due to pressure o accumulated fluid on the surrounding structures.

Signs

(1) Swelling in the hypogastric region, arising Re the pelvis and filling it in various degrees. examination reveals a distended vagina in front, c

ıctuant to palpation. The swelling does not ıar after catheterisation. (2) Inspection of the ɾill reveal occlusion of the lower end of the vagina, nay bulge on straining in the case of imperforate or retrohymenal membrane. There may be ted imperforate anus. (3) Puncture of the occluding ane in the lower part of the vagina will tap the eristic fluid. Its withdrawal will cause disappear- the swelling. (4) Radiography after introduc- a radio-opaque medium into the fluid in the will reveal the distended condition of the vagina ır without associated distension of the uterine bladder. Catheterisation will eliminate a distended bladder. Inspection of the vulva is extremely important, along with other measures, such as rectal examination and puncture of the occluding membrane in the lower part of the vagina.

sis

ırly cases the prognosis is good. In late cases, larly in the presence of complications, the prog- very much worse. Pressure symptoms may be larly serious in infants and may cause death. olpos may cause serious damage to the female tract.

ıtial Diagnosis

condition should be differentiated from hæmato- ınd from other neonatal and prepubertal swellings ypogastric region—e.g., urachal cyst and distended

Treatment

This is simple where the occlusion is due to an imperforate hymen or retrohymenal membrane. In these cases a cruciate incision or excision of the hymen and drainage of the fluid are enough. Where the occlusion is due to atresia of the lower vaginal canal some sort of plastic operation may have to be undertaken at the appropriate age.

Preliminary Communication

ECT OF COMBINED INJECTIONS OF YCORTONE ACETATE AND ASCORBIC CID ON RHEUMATOID ARTHRITIS

and more attention has been given during years to the therapeutic effect of hormones from ophysis and adrenal cortex, especially in rheuma- thritis. Two Swedish workers [1] showed that the tation of calf hypophysis in a case of severe toid arthritis caused the disease to take a more ble course. The important American research ain hormones from the hypophysis (A.C.T.H.) [2, 5] renal cortex (Compound E) [3, 4, 5] and their effect ımatoid arthritis has been a great incitement to h in this field.

ollowing is a preliminary report of an investigation effect of combined injections of desoxycorti- ne acetate and ascorbic acid on rheumatoid s.

series comprises 9 patients (6 women and 3 men) oth mild and severe rheumatic disease of the of two weeks' to fifteen years' standing.

he suggestion of one of us (E. L.) the patients eated with an intramuscular injection of 5 mg. ortone (desoxycorticosterone) acetate in 1 ml. of ırachis, immediately followed by an intravenous n of 1 g. ascorbic acid (10 ml. of 10% solution). ninutes after the injections the articular pain to diminish and the articular mobility began ease. Fifteen to thirty minutes later, the pain actically disappeared and the mobility improved h as the anatomical changes in the joints and ar atrophy would allow. All the patients reacted milar way. In some cases the improvement was ding. One of the patients was completely crippled by pain and contractures after rheumatoid arthritis for fifteen years: after *one* combined injection, she sat up with ease and moved her arms and legs about freely; all her pain had gone. It was noted that the skin became warmer and redder in the articular regions after the injection. Some patients became greatly exhilarated after the injections—more than one would expect from the mere relief of pain.

The effect lasted from two to six hours, occasionally more than twenty-four hours. It seems as though it lasts longer with each further injection. In more acute cases one or two injections have been enough to banish the pain for two or three weeks (the present observation time).

We have not yet worked out the most suitable dosage. Doses exceeding 5 mg. of desoxycorticosterone acetate and/or 1 g. of ascorbic acid do not enhance the effect. On the other hand, half these amounts seems to be equally effective. The ascorbic acid can also be given intramuscularly, but no effect has been observed after oral administration. As a rule we have waited two to five minutes between the injections. If we waited two hours we got no effect. In one case relief has been obtained for four days (at the time of writing) by the intramuscular implantation of one tablet of 100 mg. of desoxycorticosterone acetate followed by injections of 0 5 g. of ascorbic acid every sixth to eighth hour.

As far as we can determine, the pain-relieving effect is confined to the joints and adjacent regions. In cases of sciatica, myeloma, and wound and muscular pains no alleviation of the pains was observed.

As yet we have not seen any toxic side-effects after the injections. No changes in the blood-pressure have been noted, nor any mentionable effect on sodium chloride or potassium in the blood. In some cases a drop in the sedimentation-rate of the red blood cells was observed.

Further work is being done along these lines so as to ascertain how far the effects described are obtainable in different types of arthritis or other conditions, and whether the observations can lead to a therapy of these diseases.

Medical Societies

MANCHESTER MEDICAL SOCIETY

Diagnosis and Treatment of Epilepsy

ADDRESSING the Manchester Medical Society on Nov. 2, Prof. F. J. NATTRASS said that the diagnosis of epilepsy depends essentially upon accurate history-taking backed by knowledge of the varied manifestations of this disease. The electroencephalogram (E.E.G.) shows, as Hughlings Jackson postulated on clinical grounds, that epileptic attacks are accompanied by outbursts of abnormal activity in the cerebral cortex; it is still doubtful whether epileptic discharges arise in any other part of the brain. The disturbance may be localised and result only in involuntary movements or abnormal sensations on one side of the body; this is the simplest type of attack—local or jacksonian epilepsy. When the discharges are widespread throughout the cortex consciousness is affected, and if there are movements they are generalised; but movements may be absent.

In diagnosis mistakes are made particularly in respect of petit mal, and from the point of view of treatment *this title should be restricted and not applied to* any type of seizure of short duration. Another frequent cause of difficulty is the variability of the major (grand mal) type of seizure, which may be incomplete, ending with the tonic stage or with only mild convulsive movements. In diagnosis the aims should be: (1) the recognition of attacks as epileptic; (2) localisation of the areas in which the disturbance arises; and determination of the cause of attacks. As to the *aim*, distinction from syncope is the commones which may be difficult for two main reasons: people predisposed to fainting the stimulus may be slight; and (*b*) during syncope there may be fairly marked convulsive movements. There is less di in distinguishing between epilepsy and hysteria, ver *narcolepsy, and other attacks.*

While epilepsy in adults is more likely to be du organic disease, and especially cerebral tumour, th the case in childhood, nevertheless pure or idiop epilepsy begins in late life much more than is us believed. Of 1000 epileptics, 17% said that their fits occurred after the age of 40. Of 100 cases onset after the age of 40 which were followed up periods varying from 3 to 18 years, 75 were surv without any symptom or sign of intracranial tum of the 25 deaths, 10 were due to intracranial tun and 5 to cerebral arteriosclerosis.

In treatment the difference between success and fa may depend on the choice of drug, on adequate do and on prolonged trial. In the treatment of n epilepsy Professor Nattrass prefers phenytoin sodiu phenobarbitone, especially for young patients, th administration of this drug requires careful observa 'Tridione' should be used if the diagnosis of petit is certain and attacks frequent; and total and differe white-cell counts should be done every three weeks

Professor Nattrass concluded with a plea for coöperation of those in medical charge of the patien finding suitable employment for epileptics.

Reviews of Books

Nervous and Neurohumoral Regulation of Intestinal Motility

W. B. YOUMANS, professor of physiology, University of Oregon. New York and London: Interscience Publishers. 1949. Pp. 129. 29*s*.

Professor Youmans begins his monograph with a critical account of the terminology used to describe the visceral nervous system. He writes: "The earlier concept that the sympathetic and parasympathetic systems are antagonistic or reciprocally acting systems is an oversimplification." He further points out that smooth muscle is not a "biologic unity." The book contains an account of the ingenious double-pouch method for investigating the influence of the various anatomical components of the visceral nervous system on the intestine, the effect of denervation on the reactivity of the gut to adrenaline, and the reflex influence of stimulation of the peritoneum, urinary bladder, and gall-bladder on the motility of the gut. It is almost entirely devoted to the results of experiments in animals, with little discussion of their clinical relevance.

Neuroradiology

ALEXANDER ORLEY, M.D., F.F.R., D.M.R. & E., consulting radiologist to West End Hospital for Nervous Diseases, London. Oxford: Blackwell Scientific Publications. 1949. Pp. 421. 63*s*.

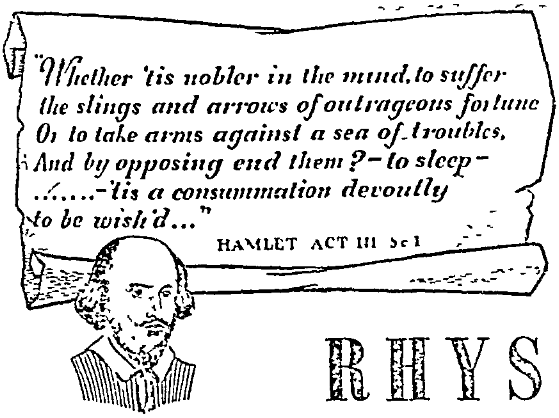
IT is sometimes said that the commonest fault of medical textbooks is that they are always several years behind current thought and methods. Dr. Orley's book suffers somewhat from this disadvantage, for it is largely based on the clinical material he collected during the 1939–45 war. In 1945 liaison with the Swedish neuroradiological school, founded by Lysholm, was renewed; and since then technique in ventriculography, and more particularly in angiography of the cerebrum, has vastly altered. The section in this book on ventriculography is to some extent outmoded, adhering too much to the old standard projections, with their emphasis upon lateral views for the filling of each lateral ventricle in turn; and so is the section on cerebral angiography, where no substance other than a radioactive preparation is suggested as a contrast medium, and the percutaneous route of injection is mentioned only to be decried. (In neurosurgical clinics in the British Isles, the percutaneous route is now being regularly used for the injection of non-radioactive substances for cerebral angiograp Such objections, however, do not apply to the sect on the technique of radiography of the skull, which clearly written and well and ingeniously illustra and those on the spine give a good general vie spinal lesions. The section on myelography is too giving no indication of the normal and its variat for comparison with the few gross lesions illustr The heading "lumbar encephalography" p very sketchy description of the technique of mye and some of the statements about cisternal myel are questionable. The bibliography is excellent the student of neurological radiology it references fully cross-indexed.

The Common Form of Joint Dysfunction: Treatment and Incidence

WILLIAM KAUFMAN, PH.D., M.D. Vermont: E Hildreth. 1949. Pp. 208.

WITH disarming candour, the author of this monog on the treatment of rheumatoid arthritis with niacina (nicotinamide) admits that few of his many exem cases were radiographed or had any but the perfunctory laboratory investigations, and that no co series was studied; so his assessment of recover failure from a "joint range index" (a figure obt from the mean of 20 joint ranges measured by a g meter, a notoriously unreliable instrument) mu regarded sceptically. Moreover, many of the case "subclinical," in that a diminished "joint range ind was found only when the patient presented himsel "check-up examination" without any though symptom of "rheumatism" until it was revealed to Climatic, psychological, and natural remissions pla big a part in this tragic disease for the most w thinker to be impressed by this book.

Plaster of Paris Technique (2nd ed. London: Ba Tindall, and Cox. 1948. Pp. 220. 16*s*. 6*d*.).—Practice can make a plaster technician, but a "*pattern book*" great value to the tyro; and this little American w beautifully illustrated, supplies a great deal that other books lack. As well as dealing with the elements subject, Prof. Edwin O. Geckeler describes in great the various types of plaster *splints, and the best* m of making them. In other chapters he describes more uses—the turnbuckle and *Winnett Orr plasters*, for in —and finally, gives helpful advice on the care of the p in plaster. Excellent *photographs form a large* part book.



"Whether 'tis nobler in the mind, to suffer
the slings and arrows of outrageous fortune
Or to take arms against a sea of troubles,
And by opposing end them?—to sleep—
......'tis a consummation devoutly
to be wish'd..."

HAMLET ACT III Sc 1

Hamlet's soliloquy is indicative of a mind so sorely troubled as to border on a state of melancholia. To a lesser degree the strain and difficulties inherent in our daily lives are responsible for many cases of anxiety neurosis and mental stress, resulting in restless and troubled sleep.

‘BENYLIN’

Expectorant

The ability of ‘Benadryl’ to relieve the cough and other distressing symptoms associated with the “common cold” represents still another clinical application of this remarkably versatile drug. The value of ‘Benadryl’ in controlling these symptoms is connected with its antispasmodic and broncho-dilator properties.

In ‘Benylin’ Expectorant, ‘Benadryl’ is combined with proved expectorants in a raspberry-flavoured syrup, which is readily acceptable to both children and adults.
‘Benylin’ Expectorant not only relieves coughs, but is also effective in alleviating nasal stuffiness, sneezing, lachrymation and bronchial congestion.

Each fluid ounce contains:

‘Benadryl’	80 mgm.
Ammonium chloride	12 grs.
Sodium citrate	5 grs.
Chloroform	1½ min.
Menthol	1/10 gr.

Dosage:—Adults: 1-2 teaspoonfuls. Children: ½-1 teaspoonful.

In 4, 16 and 80 fl. oz. bottles.

THE LANCET

LONDON: SATURDAY, NOV. 26, 1949

The Practitioner's Remuneration

the negotiations between the Ministry of Health the General Medical Services Committee. two s have been separated: (1) the size of the total to be devoted to paying general practitioners, (2) the manner of its distribution. The recent al Conference of Local Medical Committees, gh it recognised that the questions of distribution need further consideration, pressed the Minister to an early decision about the total. The committee presented him with a document arguing that um originally calculated in Whitehall fell short e amount really required—partly because more ipals have joined the service than was expected. nore importantly because the change in the value oney has made the Ministry's betterment factor alistic. Estimated on gross income this factor sented an increase of about 34% over 1939; and locument contended that it should have been at 70%. On this basis it was claimed that the money required for adequate remuneration was million, and the amount actually being received said to be short of this by some £16·5 million. is £16·5 million were used solely for increasing capitation fee for the first 1000 patients on a ipal's list. many of the serious problems arising the National Health Service Act would. it was sted, be largely solved.

e Minister has now. as requested, given his er on the question of the total sum; but the r to the General Medical Services Committee 1005) concludes that "no reasonable case can ade for any increase in the total remuneration eneral practitioners, nor any argument sub- iated to show that general practitioners as a p are inadequately paid." On examining the ences in interpretation placed on the figures he Ministry and by the G.M.S. Committee it is rent that the Ministry has corrected the com- ee's estimate by adding to it all the other items ncome reaching general practitioners from the equer. These cover moneys paid them for rnity services, for the provision of drugs, for rtaking duties in the supplementary ophthalmic ce, and for work in cottage hospitals. Also ded are the sums set aside for additional mileage ey, inducement payments, payment for training tants, and Government contributions to super- ation. These items come to £7·5 million and are rded as a national contribution towards raising practitioner's income. The Ministry also dis- s that the number of principals in the service 8,936, whereas the G.M.S. Committee's estimate ed on earlier official figures) was about 20,000. alculating the committee's own figures on the s of this smaller number of principals, and using betterment figure of 70% suggested by the com- ee—which, significantly, he neither accepts nor repudiates—the Minister believes that the total sum required to satisfy the committee's case would be £53·5 million. The difference between this and the £48·8 million he is already providing is £4·7 million. which he does not propose to grant. Primarily, he says, he reaches his decision "upon the sheer merits of the case, as revealed by the plain figures and facts as they stand." It is only secondarily that he mentions that "the proposals have to be seen also against the background of the general economic situation, and the vital national need to avoid any unjustified raising of remuneration in any field."

Doctors are very conscious of the difficulties of the economic situation today. But, as they see it, the claim they are putting forward is not a claim for an increase of present remuneration, but rather a claim for the settlement of terms left over for discussion because there was no time for detailed agreement before the appointed day. Had the Minister admitted some validity in their claim and based a regretful refusal on the financial difficulties of the country his message might have deserved a sympathetic reception. Indeed. suggestions had already been made whereby the immediate payment of extra millions of money might have been avoided. and any additional remuneration agreed on would, for instance, have been added to the superannuation credits of the profession. With the help of even a deferred payment of this type the G.M.S. Committee would have been able to proceed with some of those adjustments of distribution which are admittedly needed. But his uncompromising reply makes these adjustments far more difficult. The immediate problems are the difficulty of the young doctor in finding a place to start practice, the lack of opportunity for assistants to become principals, the real hardship felt by doctors in areas where practices are small and must remain small, and the premium placed on large lists and hurried work. All these grave faults of N.H.S. general practice could be partially repaired by the graded capitation fee. and by no other measure likely to command equally wide acceptance. It is true that THE LANCET, three years ago,[1] argued against the graded capitation fee; but we did so at a time when it was expected that there would be a universal basic salary of appreciable size, and when it was not supposed that the permitted maximum number of patients would be as high as 4000. Had these anticipations been fulfilled, many of the present difficulties would never have arisen. But the graded fee could still remedy the situation. Had the Minister even suggested providing the £4·7 million by which present remuneration falls short of his recalculation of the G.M.S. Committee's total a basis for rearrangement would have remained.

His present attitude can but alienate practitioners still further. Many of them were persuaded to enter the service on the understanding that the suggested pool of money provided was but an interim payment made to allow proper discussion of terms with their representatives in the light of the Spens promises. with full weight given to changing money values. They believed they had found in the Spens proposals a new and an agreed approach to equitable terms. Instead they are now met with the Minister's blunt refusal to depart from the basis for their remuneration which he himself originally laid down without consultation. Their consultant colleagues have at least had the advantage not only of a later and wiser Spens Committee but also of a period of negotiation and discussion before the range of their remuneration was settled. Perhaps the present experience of the general practitioners will give salutary warning to those in the consultant field who seek revision of the system of distinction awards. The too evident difficulty, in present circumstances, of establishing any new claim makes it unlikely that, even if some better way of paying consultants were devised, the Government would now endow it with the money they have promised for the awards.

---

Electrophysiology of the Mind

IN the controversies between mechanists and vitalists at the turn of the century, the apparently "purposive" behaviour of inanimate models was used as an argument in favour of mechanism. One popular analogy was that between the behaviour of a drop of chloroform brought into contact with a small glass thread coated with shellac, and an amœba engulfing some non-nutrient particle soaked in "food." In each case the particle was drawn into the drop or amœba, some portion of it removed, and the rest extruded. The action in the first case was purely physicochemical; how then in the second case could it be purposive? The analogy was crude and doubtless caused little heart-searching to the convinced vitalist, but it illustrated a fundamental point—that "purpose" and "teleology" were in the interpretations of the observer and not in the act observed. Nowadays the constructed model which mimics purposive behaviour has become vastly more complex and accomplished, and the arguments of the mechanist more sophisticated and to some more convincing. Indeed, the neomechanist would probably repudiate the very name, deny the validity of a vitalist-mechanist controversy, and argue that all he does is to point out how much of apparently "vital" and even "mental" behaviour can be executed by a machine. WIENER[1] in his book on cybernetics is careful to emphasise analogy, not homology, when discussing the possible similarities between an electronic calculating machine and the human brain; and in his Maudsley lecture this month Mr. GREY WALTER, SC.D., while owning that he "veers a little toward . . . the cybernetic discipline," specifically disclaimed it as anything more than operational analogy. Nevertheless, that "gentle pushing" towards a mechanistic interpretation of behaviour which JEFFERSON[2] noted in his Lister oration is quite evident. Whether or not we welcome such a *Weltanschauung*, the facts which workers like GREY WALTER are collecting on the interrelation of mind and brain are important and fascinating.

In his lecture GREY WALTER reviewed some of the findings and conclusions from his work on the electroencephalogram (E.E.G.). Clinical electroencephalography dates from BERGER's description, over twenty years ago, of the recording of an electrical rhythm, with a frequency of 8–12 cycles per second (c.p.s.) from the occipital region. The rhythm was in some way with vision, for it could be " to a different frequency by making the subject at a flickering light. Part of this "Berger has subsequently become familiar as the alpha rhyt which, as GREY WALTER has shown, is not a unit wave but made up of two or three components, ea with a frequency of 8–13 c.p.s. Moreover, he gone some way towards giving it a precise functi in cerebral economy. The rhythm is most pronoun with the eyes closed or when nothing particular happening in the field of vision; and it can be block by opening the eyes or focusing them on some obje GREY WALTER has further shown that in peo who use visual imagery in their thinking the rhyth is complex and variable, while in others it is simp and more stereotyped. From this, and from t analogy of an electronic model constructed to respo by movements to various visual stimuli, he that the alpha rhythm acts as a "scanning me nism" for all visual stimuli reaching the cortex; this mechanism presumably responds both to " nal" visual perceptions and to "internal" imagery. How then are "real" and "imaginar visions differentiated? The suggested answer ingenious. When a visual stimulus such as a brig light is presented, not only is alpha rhythm blocked b a small immediate electrical response is evoked in t occipital region. This "elementary evoked respons is sometimes unusually small or distorted, especia in those with visual hallucinations; and GR WALTER suggests that this evoked response lab the visual stimulus as "real" for the cortex, a thus allows it to be distinguished from an "imaginar or "thought" one.

The further investigation of the evoked respo itself has also proved fruitful. When subjects we exposed to a flickering light, they sometimes describ curious non-visual sensations, and E.E.G. recordin showed that in these cases areas of brain distant fro the occipital region were being activated at t stimulus-frequency or some multiple of it; and t site and amplitude of this activation was clea influenced by the subject's mental state. In o example a stimulus at 12 c.p.s. evoked a respo at the same frequency in the occipital region, w one of 6 c.p.s. (theta rhythm) in the temporal regio and of 24 c.p.s. in the frontal region. The tempo response seemed to be associated with emotional up and the frontal response with the intellectual anal of the visual patterns provoked by the stimul In each case the amplitude of activated respo was enlarged when the subject tried to adopt t emotional or intellectual attitude associated with t secondarily activated response; and the subject spontaneous mood seemed to play a similar part influencing these activated rhythms. The applicati of this light-stimulus technique to epileptics al provided data of interest. In some cases, especial when theta-frequency *activation* of temporal regio occurred, the subject complained of a feeling simil to the aura of his epileptic attack. Moreover, th interplay of emotional and physical factors in th genesis of an attack was sometimes clearly revealed in one case the voltage of the theta response to ligh could be doubled simply by making the psychologic environment less pleasant. A careful analysis of a e activated responses shows that they almost ainly occur together with, or on top of, a natural rent rhythm of the area activated. What is the tion of these inherent rhythms ? GREY WALTER gests that in some instances they are the electrical ction of an elaborate thought process. This view upported by the mental accompaniment—similar ach occasion for any individual—of theta activity, the tendency for the E.E.G. to take one standard tern for half a second or so before a given voluntary vement. A further possible function is that of age or memory. There is as yet no direct evidence this, but the analogy of electronic models suggests " rhythmic oscillation between cerebral elements physical basis for short-term memory is a fertile king hypothesis " ; and some slight support for is gained from the constant evocation of the same tional state when a stereotyped temporal theta thm is induced. The suggestion is in line with CHIE RUSSELL's conception of the physiological is of memory, derived from its disturbances in unds of the brain.

[2] Jefferson, G. *Brit. med. J.* 1949, i, 1105. See *Lancet*, 1949, i, 1058.

he increasingly clear reflection of brain function a whole in electrical rhythms will ultimately have be interpreted in terms of nerve-cell physiology. eady some direct correlations between electrical thms and mental states have been recognised ; l the fundamental contribution of GREY WALTER l many others similarly engaged has been to nonstrate one or two examples and so to point way to more. The findings in this field indicate e again integrative action at work in the nervous tem. They touch no more directly on the problem the liaison between the physical and psychical n does any other physiological inquiry into brain ction. The time has now come when both philosophy d medicine are likely to benefit from a thorough d critical consideration by philosophers—especially thaps those of the logical-positivist school—of the ts established by E.E.G. and similar investigations. e pruning of some of the luxuriant growth of eudophilosophical " interpretation " is likely to be e valuable outcome. It is perhaps a reflection of e fragmentation of our present intellectual life at no such detailed-critical evaluation has yet been ide, though the recent broadcast programme on e physical basis of mind suggests a beginning. me will find themselves drawn to a monism either mind or matter, but many will be content for the ment to agree with SHERRINGTON : " That our ing should consist of two fundamental elements ers, I suppose, no greater inherent improbability an that it should rest on one only."

Ætiology of Peptic Ulcer

THEORIES of peptic ulceration inevitably centre und two possibilities. The digestive power of the astric contents may be so increased as to corrode ealthy mucosa ; or the mucosa may be damaged n one or other of a variety of ways so that it cannot esist average concentrations of hydrochloric acid nd pepsin. Morbid anatomists and animal experimenters often apply Occam's razor and assume that ll peptic ulcers are formed by the same mechanism. Students of living patients are more cautious. Hypersecretion hypotheses do not explain many anomalies in the age, sex, and site distributions of ulcers ; and from analogy with other tissues it seems unlikely that a mucosal *locus minoris resistentiæ* should always arise from the same cause. Lately JAMES and PICKERING[1] have measured the pH of samples withdrawn from the stomach every half-hour in the day and hourly at night and have demonstrated striking differences in the curves of gastric acidity of patients with duodenal ulcer and those with gastric ulcer. In duodenal ulcer the mean minimum acidity reached in the 24 hours was more acid than normal, the duration of high acidities ($>$pH 2) was increased, and higher acidities were maintained at night after food had left the stomach. In gastric ulcer the duration of high acidities ($>$ pH 2) was normal, the duration of low acidities ($<$ pH 5·5) was increased, and many of the patients showed long periods of anacidity at night, due to cessation of gastric secretion. The evidence is interpreted as consistent with the view that duodenal ulcers are caused by abnormal acidity acting for abnormally long periods, but inconsistent with the view that gastric ulcers are produced in the same way.

In English and American medicine, the difficulties of hypersecretion hypotheses are not so widely known as they should be. In German medicine, on the other hand, since the VIRCHOW-GUNZBERG controversy of 1852, probably no serious research-worker has supported the thesis that excess of acid and pepsin is the main cause of the common peptic ulcer.[2] The nearest approach to natural hypersecretion is produced by sham-feeding an œsophagotomised dog. Maximal amounts of potent vagal secretion can be produced in this way, and yet, so long as the animal is kept in good general health, neither the duodenal nor the gastric mucosa is damaged. In man a duodenal ulcer is sometimes associated with vigorous acid secretion which persists day and night for weeks on end, and which is apparently almost maximal since there is little increase after histamine. Serious gastric ulcers, however, hardly ever form during these phases. and gastrectomy specimens often show a healthy mucosa. If a biopsy is done through a gastroscope, the resulting acute ulcer tends to heal as quickly in a patient with hyperacidity as it does in a patient with addisonian anæmia and achlorhydria. Further, it is not uncommon for a large gastric ulcer to form in a duodenal-ulcer patient after the age of forty, when acid secretion is tending to fall and possibly the duodenal ulcer is healing.

There is in fact plenty of animal and clinical evidence that large amounts of secretion usually fail to ulcerate the stomach, although even small amounts can ulcerate the œsophagus and jejunum. The controversial question is whether excessive amounts of secretion will ulcerate healthy human duodenum. In this issue, Dr. DOLL, Dr. AVERY JONES, and Professor MACLAGAN bring forward evidence that doctors now suffering from ulcer-type indigestion produced on an average a larger volume of juice than normal in response to histamine when they were tested as medical students. The results are statistically significant. Some will not agree, however, that this new evidence supports the hypothesis that hypersecretion is a

cause rather than a result of ulcer. Two other interpretations need to be considered. Some people probably develop hypochlorhydria or achlorhydria at a fairly early age, and so run little risk of duodenal ulceration. Most of these constitutional hypochlorhydrics will fall in the no-ulcer-type-dyspepsia group, and hence its mean secretory response to histamine will be abnormally low. In other words, the histamine test-meal picks out the group which is relatively immune to duodenal ulcer rather than the group which is highly susceptible. Then, the physiological purist may say that hypersecretion indicates an unhealthy duodenum. Normal gastric secretion and emptying are controlled by inhibitory im the duodenum and small intestine. As on a the traffic is controlled by the sector in front "come," not by the sector behind saying " The disturbance of function in a young ulcer patient often affects the entire gut, and no animal evidence that excess of acid or the pre of an ulcer can cause so widespread a d motility. It is equally likely that the primary b down is a failure of entero-gastric and entero-en inhibition, and that the functional disturbanc secretion and motility, together with the formation of duodenal ulcers, are secondary.

DEOXYCORTONE IN RHEUMATOID ARTHRITIS

THE demonstration by Hench that rheumatoid arthritis is dramatically improved by 'Cortisone' has led to the expected flow of new work. The beneficial results obtained with anterior pituitary adrenocorticotropic hormone (A.C.T.H.) by Thorn and Bayles [1] were discussed in these columns on Oct. 22 (p. 758). Boland and Headley [2] have lately confirmed the good effects of cortisone, and they suggest that it may be possible to treat less severe cases of rheumatoid arthritis with smaller doses than those used by the Mayo Clinic workers, though much further work is required before the dosage is properly worked out.

The preliminary communication from Gothenburg that we publish this week represents a new approach. Lewin and Wassén have found that the intramuscular injection of 5 mg. deoxycortone acetate, followed in 5 minutes by 1 g. of ascorbic acid intravenously, produces a nearly complete, though temporary, relief of rheumatic symptoms. The effect begins in 5 minutes and reaches its maximum in 15–30 minutes, usually persisting for 2–6 hours, though occasionally for 24 hours or longer: repeated treatments have apparently longer-lasting effects. Benefit has also been obtained in one case by implanting a 100 mg. tablet of deoxycortone subcutaneously and thereafter giving injections of 0·5 g. of ascorbic acid every 6–8 hours. If these results are confirmed, the discovery will be a great step forward; for deoxycortone is manufactured synthetically and is relatively plentiful, whereas cortisone and A.C.T.H. are both rare and likely to remain so.

From the experimental point of view the beneficial effect of deoxycortone is unexpected. Selye, in his previous work on the "alarm reaction," had found that rats treated over long periods with deoxycortone often developed an arthritis, and his latest paper [3] carries this a stage further. By injecting formaldehyde near the joints of rats he regularly produced an arthritis, and the effects of treatment with deoxycortone and with cortisone on this arthritis were diametrically opposed. If an adrenalectomised rat had been given deoxycortone for a period before the injection of formaldehyde, the arthritis was more severe than that in the control animal, whereas simultaneous administration of cortisone with the deoxycortone prevented the development of any significant arthritis. In the intact rat, the injection of A.C.T.H. 25 minutes before the injection of formaldehyde protected the rat against the development of arthritis, through stimulation of its own adrenals, and adrenal stimulation by means of an "alarm reaction" produced by various means also inhibited the dev ment of an arthritis after the injection of formaldel

The adrenal hormones are known to differ wide their actions in other fields: thus deoxycortone has a powerful regulating activity on salt metabolism, wh cortisone has little effect on salt but much on It is therefore not surprising that they have diff effects on such conditions as arthritis. Spies and St have suggested a test for cortisone-like activity observing the fall in eosinophil-counts on the adm tration of the substance under test; they found in contrast to A.C.T.H., deoxycortone had no effect on eosinophil levels, suggesting that it has therefo cortisone-like activity. Lewin and Wassén seem have altered its action profoundly by giving it in junction with ascorbic acid, but much more work be needed before their clinical observations ca reconciled with the experimental results of Selye.

NURSING TO THE LOOKER-ON

How is the young nurse to be taught the art of s gumption? Miss Josephine Brew, LL.D., who education adviser to the National Association of G Clubs and Mixed Clubs, posed and pondered this ques at a conference on The Tutor in the National He Service, held at the Royal College of Nursing last w It must be done by teaching not only knowledge values, she suggested. If the nurse does not e her training, then it is not a perfect training; for possible for a good teacher to teach any subject though it was the most exciting thing in the wo and for a bad teacher to teach even appreciation films as though it were the most boring. The t should stretch the imagination of nurses not me until they are never bored, but until they develop that matchless quality in life: zest to carry them thro dull jobs and all the irritations of institutional liv Then, Dr. Brew considered, they should be given so idea of how the mind works—of how we all rational lie, steal (affection, reputation, or opportunity, if we are to be trusted with material things); and we all indulge at times in emotional blackmail: " could you do this when I have such a headache or "I've given the best years of my life to you," (ne stopping to ask ourselves whether anyone else want them). It matters less what they are taught than th the teacher should give them some vision of greatne If the chief needs of the nurse are knowledge, efficien and humanity, she said, then the greatest of these humanity, for which the other name is *caritas*.

For the tutor who means to kindle her students this way, there are many great names in nursing to before them. It was curious that Mr. G. B. Jeffer director of the University of London Institute of Educ tion, should say earlier in the conference: "You nurses are alive and kicking young women. You m not take that material and turn it into a nice copy what you may think Florence Nightingale might ha

like if she were living in 1949.". Surely few young en have ever been more alive, or kicked more, Miss Nightingale. But no doubt in another sense as right: a nursing profession composed entirely of dynamic personalities would be decidedly unman- ble. He appealed for better handling of the young e's enthusiasm, which though it may at the outset ealistic and shallow can yet be fostered and deepened the right approach, or destroyed by cynicism and idity.

r. Elizabeth Findlay discussed the possibility of blishing a training course for a nursing degree in the University College of North Staffordshire, to be ned next year; and Mr. J. W. Bispham, education er at the Institution of Mechanical Engineers, pointed the part the polytechnics might play in bridging the between school-leaving age and entry to hospital. group discussions later, some problems of promotion e debated. It seems that higher qualifications nt less in nursing than in medicine; the nurse who taken the trouble to prepare herself for promotion seeking appropriate experience and taking addi- al certificates cannot be sure that these things will gh at all with appointing committees—a powerful ouragement to zest.

DRAMAMINE IN RADIATION SICKNESS

ADIATION sickness is one of the unpleasant features of iotherapy and is fairly common. It may be mild, prising headache, lassitude, anorexia, and nausea icient to make the patient feel miserable: or it may severe and cause vomiting, diarrhœa, and great stration necessitating the interruption or even cessa- n of the course of treatment. The cause is thought to changes in the metabolism of the cells which are most sitive to radiation, for it is most likely to occur during rapid breakdown of a very radiosensitive tumour. e incidence is increased when a large volume of tissue rradiated with a high daily dose, and the severity of sickness also varies with the site, being much more nounced when the thorax or abdomen is treated than ing irradiation of the limbs. Many remedies have n tried, but most of them have been only moderately cessful and their popularity has soon passed. Pyri- xine, a member of the vitamin-B_2 complex, found in er and yeast, has given the best results so far, though is by no means infallible. This substance not only ieves the radiation sickness but also raises the cocyte-count—a valuable effect since radiation often presses the white-cell count.

Lately Beeler and colleagues at the Mayo Clinic[1] ve been giving the new drug, 'Dramamine' (β-dimethyl inoethyl benzohydryl ether 8-chlorotheophyllinate), in iation sickness. This was first used for its anti- tamine action and later found to be remarkably ective in the prevention and treatment of sea-sickness d air-sickness[2] and in controlling vomiting of preg- ncy.[3] They gave dramamine to 82 patients with lignant disease of various kinds while they were under- ing X-ray treatment. To eliminate the psychic effects far as possible, a control series of 23 patients who lieved they were having the drug were also observed. diation sickness was present in all the cases before e drug was started. The proportion of apparently od or excellent results was much higher in the group ceiving dramamine (79%) than in the controls (13%). e best effect was obtained with 100 mg. of dramamine en $^1/_2$–1 hour before treatment and repeated $1^1/_2$ hours er treatment and again 3 hours later, making a total 300 mg. Some patients needed only 200 mg., whereas me needed as much as 400 mg. A few of the patients had side-effects, such as drowsiness, bad taste, paræsthesias, and nausea. Drowsiness was the most unpleasant of these. and 3 patients in the series had to give up the tablets after 3–4 days of constant sleepiness. In some patients whose radiation sickness was causing severe nausea and vomiting the results were improved by combining the dramamine with pyridoxine intravenously.

It is difficult to explain the action of dramamine in radiation sickness, but it is probably not due to its antihistamine qualities since other drugs with greater antihistamine effects do not control the sickness, though they do relieve vomiting of pregnancy.[4] It has been suggested that it depresses the vomiting reflex, but this view would not explain the relief of malaise, lassitude, and prostration, unless these symptoms are secondary to the stimulation of the vomiting reflex. If the results are confirmed the drug will be very useful, since it is both inexpensive and safe, but unfortunately it is still unobtainable in England.

OBSTETRICAL BRAINS TRUST

UNDER the title "Any Questions?" a meeting on the Brains Trust plan was held at the Royal College of Obstetricians and Gynæcologists on Nov. 18, and the audience evidently enjoyed themselves no less than the members of the trust—Sir William Gilliatt, who acted as question-master, Prof. W. C. W. Nixon, Miss Josephine Barnes, Mr. John Stallworthy, and Mr. Humphrey Arthure. The impromptu answers and "back-chat," not to mention Mr. Stallworthy's characteristic reminiscences, kept the proceedings very much alive.

(1) *Does surgical induction have a place in the treatment of mild cephalo-pelvic disproportion?*—Mr. Stallworthy did not think it had in the case of the primigravida but in others he had no objection to employing the Drew-Smythe catheter, and if trial labour failed he had no hesitation in performing cæsarean section. Mr. Arthure said that mild disproportion should be overcome by labour any way, so surgical induction was not indicated.

(2) *What steps should be taken to prevent sudden death in the first 24 hours of the puerperium in the woman with a serious heart lesion?*—Miss Barnes said that the coöperation of the cardiologist was essential and she was in favour of not allowing the case to go to term; immediate venesection should be employed. Professor Nixon extolled the use of a tight abdominal binder.

(3) *Is progesterone any use in the treatment of threatened abortion?*—Sir William Gilliatt referred to the difficulty of reliably estimating pregnanediol in the urine; he himself might prescribe progesterone, but its use was somewhat empirical and its value problematical.

(4) *What part does cæsarean section play in the treatment of primary uterine inertia?*—Professor Nixon thought it played a very big part and he infinitely preferred it to incision of the cervix. He stressed, however, the need for care in the diagnosis of inertia. Mr. Stallworthy agreed but did not altogether disapprove of incising the cervix when the head was already deep in the pelvis; in such cases the cervix and lower segment were often very thin and the baby's head well moulded for vaginal delivery, and cervical incision was less traumatic than cæsarean section. A fœtal mortality of 45% had been quoted following this procedure, but much of this was due to poor selection of cases. In his own department recently cervical incision had been performed 8 times in suitable cases with 100% success. In the case of occipito-posterior position where the head remained high, the membranes ruptured early, and labour continued to be inert, cæsarean section might be called for in view of the high fœtal mortality. Mr. Arthure thought that cæsarean section should be looked on as a failure of the ordinary methods of treatment; he also drew attention to the value of continuous caudal analgesia in a slow painful labour. Sir William Gilliatt remarked on the difficulty of accurately labelling and assessing a case of inertia. He regarded the lower segment operation as very safe both for the present delivery and in relation to pregnancies to come, and he had little hesitation in using it in the inert case.

Ibid, Sept. 24, p. 585.

[4] Dougray, T. *Brit. med. J.* Nov. 12, 1949, p. 1081.

(5) *A primigravida, at 34 weeks, has had a surgical induction for toxæmia ten days ago, but is still not in labour; she is draining offensive liquor, her temperature is 100°F, and the fœtal heart-sounds are still audible: what should be done?*—Mr. Arthure said he would have already used further efforts to get labour under way; he might even have used a hydrostatic bag, or he might already have done a cæsarean section. As things now are the only course was to operate after preliminary chemotherapy in order to save the baby. Professor Nixon said this was surely a case for extraperitoneal cæsarean section. He agreed that the case could not be left and the threat of eclampsia still hung over the patient. Mr. Stallworthy thought that at 34 weeks there was a fair chance that the head would be high anyway and this would make cæsarean section the wiser course, but if the head was deep in the pelvis a bag could be used. He did not care for the extraperitoneal operation because he trusted the peritoneum more than the pelvic cellular tissue to cope with infection; the technical difficulties of the operation often led to accidental opening of the peritoneum. This brought a retort from Professor Nixon that opening the peritoneum mattered little provided that it was recognised before the infected uterus was opened; it could then be simply closed. He quoted the remarkable case-mortality of 0·8% in Whittaker's series of about 300 cases.

(6) *Can ovulation occur before puberty and can conception occur before ovulation?*—Miss Barnes answered "Yes" to the first part and "No" to the second.

(7) *What is the best method of emptying the uterus in a case of hydatidiform mole?*—Mr. Arthure thought that if spontaneous abortion had already begun it should be allowed to continue; but otherwise he favoured abdominal hysterotomy, because one could then be more certain of removing the mole completely, the risk of subsequent chorion epithelioma was reduced, and the perforating type of mole could be recognised at operation. The large uterus should certainly be emptied by the abdominal route. Professor Nixon favoured evacuation from below, and Miss Barnes agreed provided uterine activity had first been stimulated by medical induction. Sir William Gilliatt recommended laminaria tents for 12–24 hours followed by evacuation from below. The tents would ensure better uterine tone and so reduce hæmorrhage during evacuation; this alone was reason enough for not relegating them to the museum. For the elderly, hysterectomy was the safest course.

(8) *What is the treatment of imperforate hymen with hæmatocolpos, hæmatometra, and hæmatosalpinx?*—Professor Nixon: "Incise the hymen." Miss Barnes: "Excise the hymen." All agreed that there was no case for laparotomy and that the need for rigid asepsis was paramount. Sir William Gilliatt added that one would not know at the time of operation that the tubes were in fact distended with blood, and the reckless folly of trying to find out by bimanual examination was at least implied.

(9) *What is the treatment of genital tuberculosis, and is dilatation and curettage ever justified?*—Mr. Stallworthy said one must distinguish between the cases without physical signs, which were discovered during investigations for sterility by routine endometrial biopsy, and those with obvious clinical pelvic disease; he had yet to see a case of the latter that had been cured without radical surgery or had subsequently become pregnant. Streptomycin might alter this outlook and initial results seemed encouraging. Curettage, though it involved a risk of spreading infection, might be necessary before the pelvic tuberculosis could be diagnosed in the first place, and endometrial biopsy could easily miss the tubercle. Miss Barnes had treated a few cases with streptomycin. Such cases must be very carefully controlled and patients with associated pulmonary or renal lesions should be excluded. Results were not likely to be conclusive for many years. Cases without large masses in the pelvis did best. Professor Nixon said that X-ray therapy should be considered.

(10) *What method of induction is safe to prevent a case booked for trial labour from becoming postmature?*—Mr. Arthure eschewed surgical induction if trial labour was contemplated but had no objection to medical induction. Miss Barnes would not even use pituitary extracts in such an induction because of the risk of uterine rupture—in fact, she did not use induction in trial labour at all and preferred to stand by her original decision. Sir William Gilliatt said that trial labour must be spontaneous and not induced labour, and that the use of pituitary extracts increased the fœtal mortality.

(11) *When should it be considered that trial labour?*—Miss Barnes thought a decision should be reached to allow labour to continue by examining the patient 24 hours of real labour or after the membranes had ruptured for 4 hours. The question of failure could considered, however, while the membranes remained Mr. Arthure disliked the setting of arbitrary time-l a trial labour had failed only if progress ceased, and had to be estimated by vaginal examination. Pro Nixon said that failure often occurred long before full d tion; fœtal distress was in itself an indication for interv Mr. Stallworthy pointed out that progress was not indicated by descent of the presenting part but als progressive dilatation of the cervix.

Sir William Gilliatt's closing remark, that fu meetings of this sort were likely to be as profitable as entertaining, was applauded.

DRINK

RATS, pigs, monkeys, and other animals readily de a taste for alcohol; about the only exception is cat, which, given the choice of milk or milk and bra will take the latter only when its hair is standin end. Dr. J. Y. Dent told this to the Hunterian So last Monday in speaking for a motion "that alcoho contributed more to the happiness than the miser mankind"; and he went on to advise that man sh drink like the cat. He divided mankind into groups: alcohol addicts, those who drink to excess temperate, and abstainers. Addicts (who in the U. number about 6% of drinkers) can never hope to alcohol temperately: for them the only way is long abstinence. Often these are intelligent and people, eager to be cured; and they should not confused with the self-indulgent drunkard of the that "insists on going to the dogs," and for whom only cure is penury. Paragons are sometimes unc fortable people to live with; and those who drin excess at least have a proper humility. To the temper alcohol makes friends seem more friendly and ener less hostile. Even the abstainer may derive satisfac from alcohol through a sense of superiority—a "so unction" denied to those who drink.

As a psychiatrist Dr. Desmond Curran was able show that alcohol is an increasingly rare cause of me breakdown. He enjoys seeing alcoholics; they engagingly shameless and their condition is of amenable to treatment. In drink they get what t deserve; he has seen a man with a robustly chee personality laugh at the snakes in his bath. Ma articles, he said, have been written on alcohol a cause of mental illness. Can it also prevent it? believes that it can. He observed during his w time experience in the Navy that mental breakdo was much less common under the stress of service sea than on shore. By analogy, might alcohol have a place in ensuring a smooth transition from trials of a day's work to the comparative calm of home?

The motion was opposed with skilled advocacy Dr. Henry Yellowlees and Mr. Archibald Crawford, Dr. Yellowlees conceded that the expectation of l for moderate drinkers was greater than for abstainer that it could afford dutch courage; enable the shy speak; possibly assist the creative worker; and pr mote conviviality. But how many "jolly good fellows were needed to balance the suffering caused through o child being run over by a drunken motorist? The motio before the meeting could not be answered in terms logic and should therefore be rejected. To the questio whether alcohol had greater potentialities for good o for evil, intelligent people could give only one answer.

The discussion revealed general recognition th alcohol is no longer the pressing social problem that i was. More than one speaker spoke, perhaps a littl wistfully, of the days when gin was 3*d*. a glass; but th ning of alcoholism was ascribed not only to the grow- cost but to improved social conditions, the restrictive ising laws, the advent of cinemas and radio, and the iged attitude to heavy drinking. From a large gather- not a single convinced teetotaller emerged to express riewpoint. Nevertheless the motion was rejected.

DENTAL DRILL OR HIGH-PRESSURE JET?

IE faint purr of the electric motor on the dental is enough to make cowards of most of us, and when faint purr is transmuted into a shattering vibration ur mouths our terror is complete. Why this should o it is hard to say. The vibration and the noise are ittedly unpleasant, but in skilled hands and with ern technique drilling is not invariably, or even ssarily, painful. It is perhaps more the feeling of lessness and the fear of that little something extra h may at any moment spring on us that bring it to the brows of the strongest. Local anæsthetics are to a considerable extent to allay these fears. Their is, however, somewhat dangerous in the hands of unwary, since too much live tissue can easily be cut y, giving rise to later irritation of the pulp with the ibility of further unpleasant sequelæ. Their use too lves some pain, since even when the needle is inserted ugh an area of locally cocainised gum its entry is east unpleasant. The numbing of pain by cold has utilised in various techniques, such as allowing a jet of cold water, ethyl chloride, or other chilling it to impinge on the tooth while the drilling is in ress. None of these manœuvres has proved wholly essful. Now from the United States, home of inven- s both credible and incredible, comes news of a new ce in which a jet of carbon dioxide carrying fine icles of abrasive aluminium oxide is directed at the h and the abrasive dusts are sucked up by a vacuum . The nozzle of the jet is only 1/18,000th of an inch iameter but the pressure behind the jet is 75 lb. per re inch. For long we have been brought up to ve that pain in the dentine is caused, among other gs, by pressure, and certain it is that the pressure of a probe on sensitive dentine is decidedly unplea- . What happens when particles launched with 75 lb. square inch behind them hit this sensitive dentine re not told. We can only hope that this invention es less fearsome in practice than it sounds.

CHLOROMYCETIN IN TYPHOID FEVER

NTIL the introduction of chloramphenicol ('Chloro-etin') there was no satisfactory chemotherapeutic it for typhoid fever. Some of the sulphonamides reported to protect mice infected with lethal doses . *typhi*; and the less soluble sulphonamides, such as haguanidine and succinylsulphathiazole, are reputed elieve the abdominal symptoms, though the evidence never been very convincing. In high concentrations cillin and streptomycin inhibit *S. typhi*, but they do clearly alter the course of the disease.

itial studies on the antibiotic, chloramphenicol, ved that it had a wide antibacterial spectrum and particulary active against rickettsial and gram- tive bacterial infections, including those produced members of the salmonella group. The original rt of Smadel and his co-workers[1] on the beneficial t of chloramphenicol on typhoid fever in Malaya was owed by that of Woodward and his colleagues.[2] ourable reports have been published in this country Murgatroyd,[3] Bradley,[4] Lomax,[5] Douglas,[6] and Patel et al[7]; in the U.S.A. by Foste These reports deal, however, only with i small noncontrolled groups: and so the usually impressive, have had to be interpre The virulence of strains of *S. typhi* v in some outbreaks the illness is severe and high, while in others it is mild and runs relatively benign course. Moreover, in assessing results the effect of previous inoculation has also to be borne in mind. With the synthesis of chloramphenicol early this year in the Detroit laboratories of Parke, Davis & Co. and the consequent improvement in supplies, it has been possible to treat larger groups. Woodward,[9] of Baltimore, has now treated 21 cases in which the diagnosis was confirmed by blood-culture. The patients were treated in the active phase of the disease, the course of which was followed by observations on the clinical condition, the duration of fever, and repeated blood, stool, and urine cultures. By the 3rd day clinical improvement was apparent, with relief of headache, cough, and delirium, and disappearance of rose spots; the average duration of fever from the start of treatment was $3^{1}/_{2}$ days. Nevertheless, some patients continued to harbour the typhoid organism and relapses ensued if the drug was given for less than 8 days.

In this issue Cook and Marmion describe the results obtained with chloramphenicol in 14 cases treated in the British Military Hospital at Fayid, Egypt. Fever began to abate within 24 hours, and had usually disappeared within 5 days; the mental state cleared, toxic symptoms began to disappear, and the appetite returned within 4–6 days. At whatever stage it was given, chloramphenicol seemed to arrest the disease; but Cook and Marmion, like Woodward, remark that intestinal hæmorrhage and perforation may still occur. There were no deaths in the 14 treated cases, and 1 death among the 11 untreated; but the results are actually better than this suggests, because all the seriously ill patients received chloramphenicol. Confirmation of these observations comes from Conti and his colleagues,[10] in Italy. In their series of 63 cases there were 4 deaths, 3 of which were attributed to treatment being started too late; and there were 9 relapses.

Chloramphenicol is undoubtedly the best chemotherapeutic agent that we have for typhoid. Very few toxic effects have been observed, and it does not appear to produce resistant strains. The one drawback is that it does not always sterilise the gut, so that relapse may follow and carriers may still transmit the disease; but this may be a question of dosage. Further trials are needed with larger doses given over longer periods, but shortage of the drug is still a limiting factor.

THE MINISTRY OF HEALTH

Sir WILSON JAMESON, G.B.E., F.R.C.P., K.H.P., chief medical officer of the Ministry of Health and of the Ministry of Education, is retiring from the public service on reaching the age limit on May 11, 1950. He has been chief medical officer since Nov. 12, 1940. The Minister of Health and the Minister of Education have appointed Dr. JOHN ALEXANDER CHARLES, F.R.C.P., K.H.P., a deputy chief medical officer in the Ministry of Health, to the joint post thus to be vacated next May. Dr. GEORGE EDWARD GODBER, F.R.C.P., will be deputy to the chief medical officer in succession to Dr. Charles.

THE Royal College of Obstetricians and Gynæcologists has launched an appeal for £400,000, of which £350,000 is required for research, building, and general funds and £50,000 for a travelling professorship. Since 1929 fellows and members have contributed £70,000.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

1599–1949

A. K. Bowman
M.B. Glasg.
SENIOR ADMINISTRATION MEDICAL OFFICER, WESTERN REGIONAL HOSPITAL BOARD

Although insignificant upon the scale of geological time, 350 years is sufficient to invest an institution with a venerable quality. The Royal Faculty of Physicians and Surgeons of Glasgow may accordingly be placed in the dignified category, hitherto occupied, so far as Glasgow is concerned, by the Cathedral and the University.

The Royal Faculty was established in November, 1599, and through its origin it occupies a unique position among those bodies in the United Kingdom which are entitled to grant a registrable qualification to practise within the profession of medicine. It was founded in a great period of British history by James VI, some three years before his succession to the English throne; and the charter of foundation executed by the King was secured by the exertions of Mr. Peter Lowe, who was perhaps the most distinguished surgeon of his time in this country. Lowe was a master of arts, probably of the University of Orleans; and he describes himself also as a doctor in the Facultie of Chirurgerie in Paris. The latter was the title claimed by members of the College of Sworn Master Surgeons of Paris, known as Surgeons of the Long Robe to distinguish them from the barber-surgeons, the lesser Surgeons of the Short Robe. His association with this college, which was established in 1216, was of importance to the Glasgow Faculty, for in the original charter of the latter, no provision was made for the admission of the barber-surgeons; and it is further proper to assume that Peter Lowe possessed a just appreciation of the standard of practice which was to be regarded alike as the aim of the profession and the right of the patient.

Lowe himself certainly had taken his responsibility seriously. During a residence of some 30 years on the Continent he had seen much service with the French armies in the field in France, Flanders, and elsewhere, and had been rewarded with the appointment of Ordinary Chyrurgion to the "French King and Navarre"—that is Henry IV. In the last decade of the 16th century he returned to Britain and ultimately he settled in Scotland. In 1596 he published in London his *Spanish Sickness*, a work on syphilis, and in the following year *The Whole Course of Chirurgerie* appeared.

In 1598 he became a salaried or pensioned surgeon in Glasgow, which at that time was a small cathedral and university city of some 7000 inhabitants—a place of less wealth and moment than perhaps some other ten towns in Scotland. The number of surgical practitioners was about half a dozen, and there was one physician. None of these practised obstetrics, which was in the hands of two midwives who were answerable to the kirk session; and the conditions of medical practice as a whole were so deplorable that Lowe's soul was revolted. It is significant that shortly after his arrival in the city, where he married the daughter of a Presbyterian minister, the Church represented to the town council and the university that some action was urgently necessary to inquire into the professional fitness of all practitioners of medicine; and with the assistance, no doubt, of the Church and of the civic fathers Lowe made made strong representations to the Scottish for the foundation of a responsible body with visory powers over medical education and The result was the charter to which reference has been made.

POWERS GRANTED TO THE FACULTY

After a preamble which touched upon the abuses which the practice of medicine was subject, the cha conferred upon "Maister Peter Lowe, our Chirurgi and Chief Chirurgiane to oure dearest son, the Pri (Henry, the heir apparent who died in 1612) with assistance of Mr. Robert Hamiltoune, Professoure Medicine (that is physician) . . . full power to call before thame . . . all personis professing or using the airt of Chirurgie."

The bounds of the jurisdiction of these officers of faculty were wide and comprehended not only the of Glasgow itself but a territory which included county areas of Lanark, Ayr, Renfrew, and Dunbart The powers conferred upon the faculty were also In addition to a tutorial function, the faculty was m responsible for the examination and licensing "accor to the art and knowledge they should be found worth exercise" of all those who professed the practice surgery; and it was also authorised to prohibit prac beyond the scope of the licences thus granted. Infri ment of these orders and dispensations became p offences punishable by fine, seizure of property, imprisonment. It was further an obligation on the off of the faculty to visit everyone hurt, murdered, poiso or "Onie other persoun tane awa extraordinarily"; with the coöpted assistance of Mr. William Spang, apothecary, to control the sale of drugs and to proh the sale of unfamiliar medicaments and of poisons exc by apothecaries charged to "take caution of the chasers." There was thus an enlightened foreshadow of the Dangerous Drugs Acts of the present day, altho it must be admitted that the faculty of the early century was more concerned with the adequateness supply rather than with the purity, suitability, strength of what they supplied.

THE FIRST UNIVERSITY CHAIR

Although the University of Glasgow had been est lished in the year 1451, and is now approaching period of its quinquennium, there was in Lowe's time

lical faculty there. It may be that the existence of Faculty of Physicians and Surgeons retarded develop- it in this direction. The first halting step was taken the university in 1637, when Mr. Robert Mayne was ointed professor of medicine. He did not, however, ive much encouragement to teach, for in 1642 the tation from the General Assembly of the Church of tland declared that the profession of medicine was ot necessary for the college in all time coming." ne was, however, granted leave to continue in his ipancy of the chair during his lifetime. In 1646, r his death, the university faculty of medicine ceased, the time being, to exist.

he system of laissez-faire was maintained until beginning of the 18th century, when one of those ll incidents occurred which are far reaching in their cts. In the year 1703 a student of medicine from land applied to the university for examination for degree of doctor of medicine. Since there was no fessor of medicine the problem confronting the demic authorities was serious. The solution was, ever, found in the fact that Robert Sinclair, the fessor of mathematics, was by chance a doctor of licine; and it was resolved that he should be ointed *pro hac vice* as professor-extraordinary of licine. For the purposes of examination two other l practitioners, graduates of the University of den, were associated with him as assessors. The lent was duly examined, adjudged qualified, and nitted to a degree. Eleven years afterwards, in 1714, university faculty of medicine came formally into ig.

THE FACULTY AS A LICENSING BODY

t is, therefore, clear that the earliest medical teaching Glasgow was given directly under the auspices of the ulty of Physicians and Surgeons. It was indeed one he duties of the president to give systematic instruc- ı to the apprentices of the surgeons, with regular examinations to assess their professional progress during their apprenticeship and at the end of their pupilage. The faculty did not, however, assume the functions of a medical school in the true sense of the word. It was not a teaching body; but for more than two centuries it retained control of the licensing of practitioners and surgical apprentices. Even after medicine and surgery had been recognised as subjects of individual study and examination in the university, the faculty obtained a decision from the Court of Session that without examination and licence the holder of a university degree was not entitled to practise surgery within the confines of its prescribed territory. This decision of the Scottish Courts was grudgingly confirmed by the House of Lords in 1840. The situation was, of course, changed by the medical legislation of 1858, and since then many of the original powers have naturally been in abeyance.

At the present time the Royal Faculty, as it became in 1909 through the regal gesture of King Edward VII, is entitled to give a registrable qualification in conjunction, chiefly, with the Royal Colleges of Physicians and Surgeons of Edinburgh; and it also grants diplomas inter aliâ in public health and dentistry. The fellowship is granted by election, after examination, to licentiates and medical graduates of universities. Thus in Glasgow the two great branches of the profession have, since the earliest days, been associated in one corporation. The practice of the Royal Faculty has here differed consistently from that which has prevailed in London, Edinburgh, and Dublin; and as an earnest of the unity of the profession offers a useful and important object lesson.

PAST MASTERS

It is at once a natural impulse and, in some measure, a moral obligation to venerate the memory of great men. Many such have been members of the Glasgow faculty, and in honouring them honour must be done to the faculty itself. The soundness of the whole depends upon the worthiness of the component parts, and no doubt the cloud of witnesses whose names appear as testimony upon the roll of fellows and who have added grace, strength, and dignity to the faculty will be remembered during the celebration of the 350th anniversary which is about to take place. Among them, William Cullen, William Smellie, and William Hunter, from a triumvirate in which the name of William seems to have possessed peculiar virtue.

It is true that William Hunter was neither a member nor a fellow of the faculty. He was apprenticed to Cullen when the latter wasi n practice in Hamilton, but Cullen was apparently at that time an unlicensed practitioner and consequently Hunter's name does not appear upon the records of the faculty even as an apprentice. Legally, however, he should have been so registered; and, in any case, his close association with the Glasgow school and his bequest to the university of the Hunterian Museum would seem to make it quite proper to include his name with the others which are mentioned here.

William Smellie, who was a practitioner in Lanark, went to London and to Paris in search of enlightened teaching on midwifery; but finding none he settled down in London and made himself the teacher. As the leading obstetrician of his time in Britain on the practical side, his work must be associated with that of William Hunter on the scientific side; and, by the combination of their efforts, the fellow of the faculty and his associate elevated midwifery from what was at best a handicraft to the position of a science.

Of William Cullen it may certainly be said that he laid the foundation of the Glasgow medical school; and it may probably also be said that he was the actual founder of modern medicine and the initiator of clinical teaching. The greatest of his pupils were William Hunter, through whom his influence passed vicariously to John Hunter; and Joseph Black who, as professor of medicine in Glasgow, initiated the doctrine of latent heat, a discovery which was fraught with such significance for science and for mankind that at the present day the world trembles at the fearful possibilities which have developed from the mechanisms to which his thought gave birth.

From this concurrence of notable minds an interesting succession was begun. Cullen taught Joseph Black; Black taught Thomas Thomson; Thomson, when professor of chemistry, taught Thomas Graham, afterwards Master of the Mint and for some time professor of chemistry in Anderson's College; Graham, in University College, London, had as a pupil Joseph Lister. Thus, after a lengthy interval, the founder of modern medicine was linked with the founder of modern surgery. All these men belonged to the Glasgow school, and their names, moreover, are all inscribed upon the roll of the Royal Faculty of Physicians and Surgeons.

When to these few representative names are added those of Allen Thomson, the anatomist; David Livingstone, the missionary explorer; William Tennant Gairdner, the physician and naturalist whose influence in the development of scientific medicine and of public health was so profound; and William Macewen whose mind lightened so much darkness and whose hand steered into the uncharted depths of cerebrospinal surgery—when we think of these names the greatness of Peter Lowe's accomplishment becomes apparent. The closing words of his epitaph, engraved upon his tombstone in the churchyard of Glasgow Cathedral, speak of humility and mortality; but while they describe the temporal quality of the things of the body, they throw into high mental relief the eternal nature of the things of the spirit:

Ah Me I Gravell Am And Dust
And To The Grave Deshend I Most
O Painted Piece of Liveing Clay
Man Be Not Proud of Thy Short Day

With these thoughts in mind, there will be many who will wish continued God-speed to the Royal Faculty.

FELLOWSHIP FOR FREEDOM IN MEDICINE

OUTLINE OF POLICY

At the first annual meeting of the Fellowship for Freedom in Medicine, held in London on Nov. 19, Lord **Horder**, the chairman, announced that the membership was now 2940; in the last nine months an average of 25 new members had joined each week. He often met colleagues "at street corners—well, let us say, in nursing-homes—who wish good luck to the fellowship"; and, obviously there were many who, though they sympathised with its aims, had not joined. Cheques have been sent by American colleagues as expressions of good will.

Lord Horder reaffirmed his hope that through the fellowship the medical profession might achieve unity, without which there was no hope of retaining autonomy. The British Medical Association had provided no shield against State domination. Far from closing the ranks of the profession to present such a shield, it had dissipated its strength by forming three autonomous bodies that negotiated direct with the Ministry, and by setting up a ghost of itself, called the Guild, in the probably vain hope that an action would not lie against it that might lie against the association itself. At what point should the fellowship step in? "This pusillanimity in the leadership of the profession is not getting us anywhere. Time is pressing: things are happening."

POSSIBLE AMENDMENTS

Members were invited to comment on possible amendments to the National Health Service Act suggested by a subcommittee of the executive. In presenting the subcommittee's report, Dr. A. C. E. **Breach**, its chairman, explained that the fellowship's aim was an entirely new amending Bill.

Preservation of Private Practice.—The report suggests that every citizen should have the choice between (*a*) remaining in the N.H.S. but receiving a grant-in-aid from the State if electing to occupy a private bed in a hospital or nursing-home, the grant being based upon the statistical cost bed in a public hospital ward which could otherwise been occupied, and coupled with this the free drugs and certain agreed appliances; and (*b*) opting out service altogether and receiving a refund from the based on the pro-rata cost of the service, to enable individual to make a private contract for his medical needs. "To a very large section of the population," says the report "the enforced contribution bulks too large to be ignored and they feel themselves compelled to take advantage of the facilities offered by the State in return."

"Under present conditions, the cost of the Service wi rise in that the State will be paying a grant-in-aid to Mr. Jones in a nursing-home at the same time as Mr. Jones's bed in public ward is occupied by Mr. Smith, who would otherwi have been awaiting admission; but this is a far less co and more immediately practical way of reducing the waiting lists than a corresponding extension of the hospital service would entail."

"We are exploring the possibility of a plan whereby sum the Government could reasonably be expected to ret annually should be used to cover the premium required for comprehensive sickness insurance on a private basis."

Ownership of Goodwill.—"We recognise that a large num of doctors do not now wish to recover this, but we beli that the *right* to do so is essential to freedom. We rec mend that the Act be so amended as to give doctors, both and in the future, the option to recover the ownership, to build up anew the goodwill of their practices, both priv and State. This would involve repayment of any compens tion already received, and the restoration of the right buy and sell."

Dr. **Breach** observed that the Medical Practic Committee, properly constituted, should be a safeguard but every member was appointed by the Minister, lately its actions had shown to what a large extent was controlled by him.

Dr. J. L. **McCallum** testified that in London it now impossible for a young doctor to enter gene practice "except as a chronic assistant or perhaps some black-market deal in house-ownership." T of the burden of debt under the old system of purch was nonsense; and young doctors were now much wo off, even with the basic salary. Dr. J. A. **Moyse** add that in his area 104 applications had been received a single practice vacancy.

Medical Education.—"Appointments to the boards governors of teaching hospitals must be free from the ris political patronage, and the boards guaranteed comp autonomy in the exercise of their academic functions."

Powers of the Minister.—The report recommends adoption of the method of constituting local executi councils as a pattern for all other administrative committe the relevant interests being directly represented. T Minister's powers are divided into three classes: (1) th that are admittedly essential; (2) those that are free fr objection only if proper facilities for arbitration exist; (3) those that are entirely objectionable. Under the l two headings a number of specific changes in the Act proposed; and the report urges that a standing arbitra authority should be set up to settle all matters in conne with the service where agreement is not reached, and order the payment of compensation where individual rig are violated. Furthermore, the exercise of powers of co pulsory acquisition of land, hospitals, nursing-homes, houses of professional men should be made subject to app to the law-courts.

Members agreed to a resolution by Dr. C. P. **Walla** that a court of arbitration should be set up at o "in view of the Minister's reply to the general pra tioners' demand for adequate remuneration." H. H. D. **Sutherland**, a member of the General Medi Services Committee, hoped that no-one would take Minister's letter as the final word. "We were expect something like this"; and pressure would be continu

Professional Secrecy.—More stringent safeguards needed.

Penalties.—The report claims drastic amendment of penal clauses; the right to appeal to the courts from decisi of the tribunal; and the right to attach a moderate e medical association of a doctor's house on sale. " The ration of this right would provide an inducement to the ng doctor to sell the house to his successor and would l the grave inconvenience caused when the only suitable e for practice is sold in the open market before the ssor has been appointed."

r. J. A. GORSKY pointed out that complaints must eported by executive councils to what purported e an independent tribunal; this was not a judicial n administrative tribunal, and thus it was not bound ive the reasons for its decisions. Under section 42 e Act, not only the executive council but any other n might take his complaint direct to the tribunal. other person might be the Minister of National rance if he thought that his regulations had been gressed by a practitioner; and such a position was erable. The two aims must be to replace the inistrative by a judicial tribunal, and to get rid of 'other person."

spital Medical Staff Committees.—These should be torily recognised as advisory bodies with the right nder advice direct to boards of governors and hospital gement committees.

muneration.—The main principles in the assessment of neration should be laid down in the Act. Full-time ltants should have predetermined salaries, and part- consultants should be given every encouragement to lop private practice. As to general practitioners, the nmendation that smaller lists should carry a higher ation fee is accepted.

swering a question whether the grading committees d not be dispensed with, Dr. E. C. WARNER, the wship's hon. secretary, observed that the formation hese committees had been advised by the Spens mittee, whose recommendations the profession had pted. There was, however, a serious lack of uniity in grading; and the grade of senior hospital ical officer was being used to save the Treasury ey, and to degrade men who had for years been pted by their colleagues as specialists. The Minister being urged to set up a central appeal mechanism, h would go a long way towards rectifying injustices. he proposed distinction awards were described by REGINALD PAYNE as " the biggest piece of academic oolery sponsored by the colleges." It was a terrible g for the president of the Royal College of Physicians e paid by the State. The profession had looked to colleges for moral leadership; but the chance had neglected. The colleges had lost the respect of the lic and the profession; and the proper place for them in the Ministry of Health.

r. GORSKY said that because of the word " autonomy " profession was in a mess. At this juncture the I.A. was powerless to do anything about the general titioner's pay, because the demand had been made he General Medical Services Committee. In devisarbitration mechanism, care would be needed with rd to autonomy; for the Minister might play off body against another. "Where are we going with nomy? To blazes."

e report contains further sections recommending that ents should pay a small fixed charge for each item of ice rendered by a general practitioner; and that the ers of radiological and similar practices should be comsated for the loss of the right to sell them. The committee also considered the vesting of hospital ownership in dy consistituted on a national basis.

The report is to be studied by the executive body who l determine which sections should be incorporated a further amending Bill.

FURTHER BUSINESS

Members agreed that medical students should be mitted as associate members; and the advisability electing laymen to associate membership is being udied.

GENERAL PRACTITIONERS' REMUNERATION

THE following letter, to which we referred briefly last week, has been received by Dr. Charles Hill, secretary of the British Medical Association, from Sir William Douglas, permanent secretary to the Ministry of Health:

Dear Dr. Hill,

On October 31 you sent me two resolutions passed at your Annual Conference, the second of which dealt with the question of calculating the total amount of the central " pool " used in the remuneration of general practitioners. You suggested that this question need not await any revision of the more detailed Tables dealing with the distribution of this pool, and other income. among the general practitioners.

I agree that we have now sufficient information to determine the adequacy of the total remuneration which is going to practitioners taking part in the National Health Service, and I think it may be useful if I set out in the following paragraphs what I think are the salient facts.

(1) Before the war there were about 17,900 principals in general practice whose total income from practice was £28·14 million, of which £11·35 million was for practice expenses and £16·79 million was net income. The Spens Committee thought that the net remuneration before the war was too low, and their recommendations would have meant that the total pre-war remuneration should have been:

	£m.
Net income	19·89
Practice expenses	11·35
Gross income	31·24

(2) The initial central " pool " for the new National Health Service was arrived at by assuming: (*a*) that practice expenses had increased by 55%; (*b*) that there should be a betterment factor of 20% on net incomes; (*c*) that account should be taken of the increase of population of 3%. The new " pool," therefore, was:

	£m.
Net income (£19·89 m. + 20%)	23·87
Practice expenses (£11·35 m. + 55%) ..	17·59
	41·46
Plus 3%	1·24
	42·70

This, however, was for the whole population. It was agreed that 95% of the population should be regarded as possible Health Service patients, so that the total " pool " was 95% of £42·70 m., or £40·57 m. This was estimated to be equivalent to 18*s.* per head of the 95% of the population.

(3) Although the " pool " was so calculated as, by itself, to give a betterment factor of 20% on net incomes, other sources of income under the scheme were made available which substantially increased the real betterment factor. Inasmuch as *all* practice expenses were attached to the " pool," these additional moneys represent net income.

(4) The actual sums of money available for the financial year 1949–50 are now estimated to be approximately:

		£m.
(*a*)	The central " pool " (after taking account of current population)	41·3
(*b*)	Inducement Fund	0·4
(*c*)	Additional mileage money	0·5
(*d*)	Maternity medical services	2·5
(*e*)	Payments for provision of drugs	1·2
(*f*)	Supplementary ophthalmic service	0·2
(*g*)	Payment for trained assistants	0·1
(*h*)	Payments to general practitioners in cottage hospitals	0·2
		46·4
	Exchequer superannuation contribution	2·4
		48·8

(There are also, of course, other sources of income from practice which ultimately fall in whole or part on the Exchequer which are not included in this list—e.g., payment for work done for local health authorities, fees for anæsthetics in dental cases.)

(5) The number of principals is now estimated at 18,936, which is an increase of 5·8% over the 17,900 assumed when the first calculation was made. At the same time the civilian population since June 30, 1939, has increased by about 4·3%, and this increase is reflected in the pool. If the number

of doctors had increased in the same proportion as the population in general there would have been no question of any adjustment for the number of doctors. As it is, we have in effect allowed for an increase of 4·3% in the original number of 17,900—i.e., we have allowed for about 18,670 doctors on the Spens scale, plus betterment of 20%. The actual number being 18,936, there might then have seemed to be a case for a further increase of the original "pool" of 1·5% —i.e., of just over £600,000. This argument, however, would have ignored all sources of income outside the "pool."

(6) I understand that the Association's proposal is, *shortly*:

(*a*) to ignore any sources of income outside the "pool" such as are mentioned in (4) above, and

(*b*) to work out the "pool" total afresh on the basis of the current number of principals and with a 70% betterment factor on gross incomes, and

(*c*) to apply any new capitation fees resulting therefrom, as from July 1, 1948.

If (*b*) were to be worked out on the basis of 18,936 principals the new "pool" would amount to about £53·5 m. This figure compares—as, in the Minister's opinion, there can be no question of ignoring the income outside the "pool" —with the sum of nearly £49 m. already being provided under present arrangements in the way which I have shown.

The Minister is clear that in the light of these figures no reasonable case can be made for any increase in the total remuneration of general practitioners, nor any argument substantiated to show that general practitioners as a group are inadequately paid. Nor, in his view, could any claim be justified that any future alteration of remuneration at any later date should be made retrospective, either to July, 1948, or to the present day. This view rests upon the sheer merits of the case, as revealed by the plain figures and facts as they stand.

The Minister cannot, therefore, entertain any claim by the Association for larger total remuneration.

Moreover, quite apart from this clear conclusion, to which the analysis of the facts must lead him, the Minister would point out that the Association's proposals have to be seen also against the background of the general economic situation and the vital national need to avoid any unjustified raising of remuneration in any field. Under such conditions it becomes even more apparent that it would be impossible for him to justify any increase for general medical practitioners at the present time.

In the circumstances I am wondering whether anything useful would result from the suggested further discussion with representatives of your General Medical Services Committee. If, however, you still feel that such a meeting would be desirable, I need not assure you that I shall be only too happy to arrange it.

GENERAL MEDICAL COUNCIL

PRESIDENT'S ADDRESS

AT the opening of the 176th session last Tuesday, Prov. DAVID CAMPBELL was elected President in succession to the late Sir Herbert Eason.

In his address the new President paid tribute to his predecessor.

> "The ten years of his presidency were momentous years for the Council. Its administration had to cope with a flood of medical men seeking asylum from a crazy Europe; new disciplinary situations emerged from the stresses and strains imposed by total war; and the general urge for reform, or at least the desire for change which marked the years of sacrifice, led the Council to a searching examination of the basis of medical education. In all these activities the President played a major rôle. He had also the wisdom to foresee that when men's minds were attuned to change the time had come for a review of the legislation which gave birth to this Council and under which we labour . . . when, as we may hope, a new Medical Act is passed in the not too distant future, it will place the hallmark upon a great presidency."

The President went on to welcome two new members—Lord Nathan and Dr. O. C. Carter.

Reviewing the Council's duties, he suggested that the health services would be judged not by the plan of organisation or the methods of finance and control, but by the quality of the medical advice, skill, and care offered to the people.

"In the last analysis," he continued, "that upon the intelligent interpretation and scientific knowledge in its application to the needs individual, and on the moral stature of the In short, medical education and medical ethics ultimately the dominant factors in determining degree of success of any health service.

"This Council—the General Council of Medi Education and Registration of the United Kingdom, give it its full though little known title—representati as it is of the Crown, the profession, the universiti and the medical corporations, is the device of governme charged with one main duty, to protect the public by raising and maintaining a high standard in profession both of conduct and of education. And it hardly be argued, in these days of great and advances in medical science and practice, that medi education ends with the first registrable qualificatio

EMPIRE RHEUMATISM COUNCIL

AT the annual meeting of the Empire Rheumat Council, held in London on Nov. 23, Lord Horder, chairman, reported that the Council's investigation the causes of rheumatoid arthritis, begun in 1916, lately been completed. At the Hospital of St. John St. Elizabeth, investigation had revealed no signific difference in allergic tendency between sufferers fr rheumatoid arthritis and control non-rheumatic subjec On the other hand, among patients suffering from rheum toid arthritis and with demonstrable allergy, the incide of infections, past or present, was much higher among non-allergic sufferers from rheumatoid the figures were 83% and 27% respectively. The nor synovial membrane had been proved impermeable the natural blood-group antibodies; but in the arth joint this barrier was broken down and the nat antibodies diffused freely into the synovial fluid. In field of postgraduate education, the Council's co at the Apothecaries' Hall had each been attended capacity.

The Council's income during the past year has £10,287, compared with £9408 in the previous year.

Public Health

POLIOMYELITIS, 1949

PRELIMINARY OBSERVATIONS

W. P. D. LOGAN

M.D., B.Sc. Glasg., D.P.H.

MEDICAL STATISTICIAN, GENERAL REGISTER OFFIC

NOTIFICATIONS of poliomyelitis in England and W during 1949 (up to Nov. 12) reached their maximum the middle of October, more than a month later th the epidemic of 1947. Though the weekly notificat are now diminishing, it will be some weeks before 1949 epidemic can be seen as a whole. Meanwh however, it is possible to study some aspects of first part of the epidemic and to make comparisons 1947.

The general shape of the curves of the two epidem —1947, and 1949 so far as it has gone—should be alrea familiar to readers from the chart published from ti to time in THE LANCET (see p. 1009). It is unnecess therefore to discuss in detail differences between general trend of the disease in the two epidemics. Inste attention will be directed towards sex, age, and regio variations in numbers of notified cases and of deaths.

Table I shows the numbers of original and correc notifications and corrected notification-rates in main geographical regions during the September quart (July, August, September) of 1947 and 1949. In 19 the region with the highest rate was North II (Cumberland Westmorland, and the East and North Ridings of York while the lowest was the South-West (Cornwa shire), while the lowest was the South-West (Cornwa

m, Dorset, Somerset, and Wiltshire). In 1949 the h-West had the highest rate, while North II was d lowest, the lowest being Wales II (North Wales). e was, however, no general tendency for regions high rates in 1947 to have low rates in 1949 or versa. For instance, the South-East had relatively rates and Wales relatively low rates in both s.

nsidering now the density aggregates (bottom of I), in both years the rates were lowest in county ughs and highest in rural districts, but the relative rence between these two types of area was rather in 1949 than in 1947.

e two columns of table I which express corrected ications as a percentage of original notifications ate, considerable differences in this respect between rent areas. For the country as a whole, the effect orrection was practically equal in the two years— in 1947 and 85% in 1949. In both years the effect orrection was less apparent in rural areas than in s, suggesting either that the accuracy of original nosis was greater in the country districts than in towns, which seems unlikely, or that less effort was made in country areas to report amendments of diagnosis; a third possibility is that in country districts amendments of diagnosis to and from poliomyelitis more nearly balanced one another than in the towns.

Table II provides a two-way analysis of original notifications during June–October in each of the two years by main regions and by type of area. The experience in the two epidemics is compared by the percentages shown in the right hand section of the table, no account being taken of possible population changes in the two years. For the country as a whole, notifications in 1949 during the 22-week period were 40% fewer than during the corresponding weeks of 1947, this proportion being approximately maintained in each of the three density aggregates. An outstanding departure from this level occurred in the South-West, where there were $1^1/_2$ times as many notifications in 1949 as in 1947, the excess being greatest (89%) in the urban districts. By contrast, notifications in the rural districts of Wales in 1949 were only a fifth of those two years before.

In all the tables cases of polioencephalitis have been included with poliomyelitis. The second footnote to

e and September quarters for a transfer of cases from age-group 5–9 years to a younger age.

able IV, which is in two parts, (*a*) 1947 and (*b*) 1949, ents the age-distribution of corrected notifications egions and density aggregates during the September rters only. Space does not permit a detailed dis- ion of the table but the data have been presented in for the benefit of those who wish to study them. nts to which attention may be drawn are the high portion of male cases at ages 5–9 years in 1949 in the th-West region (28%) and in rural districts (26%). erwise there was considerable uniformity of age- ribution over most of the country.

able V compares deaths in the 126 Great Towns, sified by regions, during June–October, 1949. It not been practicable to make a similar comparison 1947 because weekly poliomyelitis deaths were not orted in that year. Death-rates were highest in the uth-West region (48 per million) and in the South- st excluding Greater London (45 per million). Lowest es were recorded in the Midland region (20 per million) d in Greater London (28 per million). Table V also es original notifications and notification-rates (for e Great Towns only) and shows the number of deaths each region per hundred notifications. It should be noted that the deaths and notifications here are not strictly comparable, if only because a number of deaths occurred in Great Towns (e.g., in hospitals) of cases notified in areas outside the Great Towns. The effect of this has not necessarily been the same in all regions, so these deaths/notifications ratios must be accepted with caution. Nevertheless they provide some indication of the extent to which the fatality of poliomyelitis apparently varied among the different regions. Fatality so estimated was highest (26%) in Wales, followed by the East (17%) and the South-West region (16%). It was lowest in Greater London (7%) and in the Midland region (9%). Averaged over the 126 Great Towns the ratio was 11%; but, for the reason given above, this is probably an overestimate of the true fatality-rate of notified cases. The comparable ratio for 1947 is not known.

TABLE V—ACUTE POLIOMYELITIS (INCLUDING ACUTE POLIOENCEPHALITIS): ORIGINAL NOTIFICATIONS AND DEATHS; RATES PER MILLION LIVING AND DEATHS PER 100 NOTIFICATIONS, JUNE TO OCTOBER, 1949 (22-WEEK PERIOD); 126 GREAT TOWNS OF ENGLAND AND WALES BY REGIONS (EXCLUDING NON-CIVILIANS)

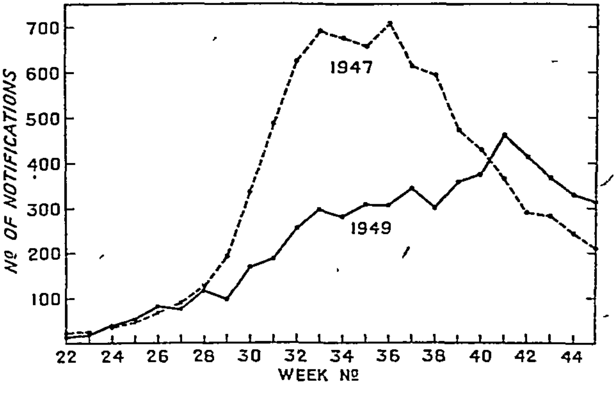
Poliomyelitis

In the week ended Nov. 12 notifications in England and Wales were: poliomyelitis 293 (318), polioencephalitis 23 (12). Figures for the previous week are shown in parentheses. Multiple cases were reported from the following counties:

London 50 (55), Bedford 6 (2), Berkshire 7 (3), Buckingham 2 (4), Chester 16 (10), Derby 3 (2), Devon 3 (3), Dorset 7 (3), Durham 3 (2), Essex 24 (26), Gloucester 6 (9), Hereford 4 (2), Hertford 4 (9), Huntingdon 5 (0), Kent 15 (16), Lancaster 26 (32), Leicester 12 (3), Lincs, Lindsey 5 (13), Middlesex 14 (17), Norfolk 7 (5), Northampton 4 (1), Northumberland 4 (2), Nottingham 9 (8), Oxford 2 (2), Salop 2 (0), Somerset 2 (11), Southampton 9 (13), Stafford 7 (3), Suffolk, East 2 (2), Surrey 6 (14), Sussex, East 5 (9), Sussex, West 1 (3), Warwick 7 (8), Westmorland 3 (1), Wiltshire 2 (1), Yorks, North Riding 2 (2), Yorks, West Riding 36 (50), Glamorgan 4 (7).



In England Now

A Running Commentary by Peripatetic Correspondents

G.P.'S PRAYER

Don't take our midder away, Mr. Bevan,
Don't take our midder away.
You've left us the chronics
And those who take tonics
And those who have plenty to say,
The aged and grumpy,
The fussy and jumpy,
So don't take our midder away.
Those merely catarrhal,
Or seeking apparel,
Add strength to the dismal array
Of myopes, bronchitics,
And osteoarthritics
—So don't take our midder away.

Removing cerumen
Demands no acumen
I've squirted out tons in my day.
Certificate-writing
Is not too exciting—
Please don't take our midder away.

* * *

If anybody thinks he would make a lovely Television Doctor, I should warn him (or her), before he rushes off to Alexandra Palace, that it is not easy. In the first place, the studio is unbearably hot; the officials are in their shirtsleeves, but as you are to be "on the screen" you must sweat beneath a thick coat. Then the muddle of microphones on lazy-arms, actors waiting for cues, cameras advancing and receding, worried-looking studio managers wearing earphones, and make-up girls all conspires to induce you to forget your lines or to repeat them in a steel-like manner. Either is fatal. If you forget your lines you must still keep talking—for there is no "retake" on television—and you will lapse for protection into a mass of clichés and string out all the words you have seen in books, like "commence" and "terminate," sprinkled with "wells" and "actuallys." You may think you can avoid this by looking down at the script all the time, but if you do you will annoy viewers just as much. The intimate yet not too breezy manner necessary for television is very hard to attain. Perhaps it comes easiest to women, but not to all of them. And as a final demoraliser, I was told: "Of course, the greatest menace is the person who will make jokes; poor thing, he doesn't realise how annoying he is to all concerned." After that I crept out over the cables and walked down the stairs. As a peripatetic correspondent, I felt I could not ring for the lift.

* * *

It is rather strange that although our profession includes one or two outstanding orators who can successfully compete with speakers from any intellectual sphere, medical men are with rare exceptions deplorably bad in presenting communications at society meetings. Their knowledge may be profound; but they appear to lack the most elementary notion of preparation for an audience. Eloquence is not demanded, nor is mellifluent sonority, but the usual mumbled or muttered monotone which tails off into complete inaudibility at the end of every sentence is a wretched ordeal for those of their audience—and they comprise a fair proportion—who must admit to be what is euphemistically called a little hard of hearing.

The stereotyped instruction (or even order) to restrict themselves to 15 minutes has little or no influence on speakers, who might almost require an almanac rather than a clock for their regulation. The unhappy chairman writhes impatiently, divided between a hesitancy to give offence by abruptly terminating a discourse and his obligation towards others who are entitled to participate. Recently I encountered an example who at the end of 16 minutes had not emerged from the stage of self-introduction, and who after another 20 minutes expressed resentment at a reminder from the chair that even if he was a protagonist he was not the entire caste. Speakers should pay their audience the compliment of preparation, though admittedly this means considerable trouble. The subject matter abridged, pruned, polished, and repeatedly against the watch until a maximum of 14 minute ensured. As a golden rule, it is far better to say n little than a little too much.

A guide and warning are provided by Mark experience. He had wandered by chance into a hall and heard a preacher soliciting funds for a intention. At the end of 10 minutes so moved w by the sentiments that he resolved to realise possessions and donate the proceeds. After a 10 minutes he decided that the loose silver in hi would suffice. And when after another 10 min collection plate reached him, he abstracted tw for his own expenses.

* * *

I cannot leave unchallenged my fellow corresp note of Nov. 19 (p. 958) on the short-term r quassia clysters. When I was a student in B there was another student who had a peptic ulc Kretchmer, he was of pyknic build and sociable tion, which went badly with his physician's ord bland diet, solid and fluid. After abstemiously wi a succession of those gloriously "wet weekends punctuate the American student's otherwise existence, he was goaded into rebellion. On t occasion he guaranteed his conviviality by mea Higginson and a bottle of port. Port, I ima deference to the Oslerian tradition, for his objec have been attained with more domestic liq uncertain origin but unquestioned potency. Or caution may have informed this choice. At a there was leisure for repentance, for he was r with a "regular" hangover and an intractable p He was thereafter quoted as an example of bur candle at both ends.

* * *

The other morning, while I was shaving (w when my most brilliant ideas come to me), I w dering whether a perfectly fresh clouded yellow *croceus*) I had recently caught was an immigrant been born in this country. Having no net at t I had caught it by gripping one of its wings betw left index and left thumb as it perched imbibing Michaelmas daisy, and a perfect mirror image of pattern had been impressed on my thumb. That su that the insect had just emerged, and then I reme that the pigments of butterflies are often pteri that pterins are being tried in the treatment of and leukæmia. Had anybody thought of butterfl as a source of pterins for that research? Less th hours later, almost the first medical journal that I up (the *Journal of the Philippine Medical Ass* for June) contained an article on the successful an extract of the wings of a Philippine butterfly, *hecabe*, to kill the plasmodia of malaria, the substance being a pterin. So much for my brillia —and for Mr. Piddington.

* * *

A hitch in air travel reveals the strangest among those misguided enough to indulge i pastime. For unexplained reasons, B.E.A. deci cancel its service to Amsterdam but said that, of passengers to that place, three might travel first K.L.M. service and three by the second, same day. In the friendly dispute that follo Dutchman revealed that he had to get to urgently because he was importing eight elephan there would be no-one there to receive them. his priority!

Pondering on the shortage of nurses while waiti one to chaperone me, I noticed my H.P., a young happily disappear into a cubicle to examine a young labourer. Here, I thought, is another unpublished advantage in having women doctors. reflections made me realise the flaw in this argu surely the labourer should demand a chaperone. he did, should it be another man or a woman? Pe Mr. Bevan will create another class of hospital servants to fulfil this need.

Letters to the Editor

THE HEALTH OF NURSES IN HOSPITAL

R,—I should be glad if you could spare a corner of correspondence columns not occupied by theo- al controversy (Deus, Paley, and Fisher *v.* Voltaire, on, and Platt) to allow me to congratulate Dr. Court is admirable article in your issue of Nov. 12, and also sk your powerful support for a solution of the lems that he raises.

ere are no doubt some things which are better under the National Health Service, but the medical of nurses in hospital is certainly not one of them. hospital which I serve it has been the admirable ition that the junior physician should act as physician- arge of the nursing staff, and it was established by two predecessors that the capitation fees were ved by the institution and paid into a nurses' are fund. Since July 5, 1948, such an arrangement een impossible. The Minister insists that the medical of nurses in hospital is a general-practitioner service, that the medical officer must be under contract the local executive council and hold a "limited list" iving 10% less than the usual capitation fee). It is ous to anyone who has had experience of this work, equally plain from a reading of Dr. Court's paper, much of the work required in the medical super- n of nurses lies altogether outside a general-practi- r service. The work is comparable to the medical vision of children in boarding-schools or of workers zardous industries; and it has long been recognised special arrangements outside the National Health ice are required for such services. During the last teen months I have endeavoured to get this point iew accepted by discussion with my colleagues, ugh the British Medical Association, at the regional ital board, and by correspondence with a friend in Ministry of Health, powerful, well-intentioned, and ressive. All these approaches have failed; the ssus has not lifted his potent finger, while his pheral servitors, clamouring insistently for their ificates to be signed, have ultimately compelled refusal to do business with them.

ere is a suggested solution on which I should value criticism and that of your readers. The Minister ld instruct boards of governors and management mittees to proceed to the appointment of a physician- harge of the nursing staff in all hospitals. The t status of this physician should not be laid down; n he will be the junior physician on the staff of the pital; sometimes he will be a family doctor; seldom he be a medical registrar, junior resident physician, esident medical officer—not that this last group is hout the necessary enthusiasm or experience, but are men on the move and some continuity of medical is essential in this work. In some areas the physican ointed will have the medical care of nurses in a group hospitals. The appointment should be made on joint recommendation of the matron, the nursing ncil, and the medical committee of the hospital cerned. The board of governors or management mittee should pay the physician a salary represent- a capitation fee of not less than £2 per annum for h nurse, an arrangement being made that the capita- n fees for these nurses should be the property the board of governors or of the management nmittee.

Although the exact status of the physician should t be laid down, yet the standard of medical care pected in all hospitals should be defined in detail. e time of routine examinations, the frequency of X-ray examinations and blood-counts, the nature of prophylactic and diagnostic procedures, the form of records to be kept, and so on—all this should be determined centrally after consultation. The matter has some urgency since the Ministry is (rightly though tardily) planning to include nursing staffs in a controlled B.C.G. experiment. It is illogical to take central action in this relatively limited field while more important aspects of the health of nurses remain unconsidered. Moreover, the organisation of the B.C.G. experiment itself would have been facilitated if the general medical care of nurses in hospital had first received attention.

Derby. DOUGLAS HUBBLE.

SIR,—Dr. Court's excellent paper in your issue of Nov. 12 gives me the opportunity of reporting a short investigation that has been carried out at the Queen Elizabeth Hospital during the past three years.

Shortly after the war some concern was felt regarding the number of nurses developing pulmonary tuberculosis, and it was thought that one possible source of infection might be a higher than normal incidence of unsuspected open tubercle amongst hospital patients. With this idea in mind it was decided to examine clinically and radiologically the chest of every patient admitted to one of my surgical wards (34 beds); and the sputum was tested for tubercle bacilli.

During the thirty-five consecutive months admissions totalled 1908. Of these patients 35 showed positive X-ray findings and had positive sputa; but 28 of them were cases of known pulmonary tuberculosis admitted for surgical treatment. Thus the number of general surgical patients with hitherto unsuspected open pulmonary tuberculosis was 7 —i.e., 0·37% of all admissions. The "thoracic" cases were all nursed in special side-wards, with special precautions laid down by the physicians; but without special investigation these 7 would probably have escaped recognition, since their coughs were minimal and their general state of health appeared satisfactory.

In addition, there were 14 general surgical patients with positive X-ray findings but negative sputa. On admission these were presumably of no danger to the nursing staff but they might become so should they develop postoperative chest complications; and they themselves might fare ill in such an event. In any case, according to the phase of the lesion, some active treatment might be called for.

It may be said, then, that the population of the average hospital surgical ward carries no higher incidence of open tubercle than does the general population—i.e., about 4 per 1000. Nevertheless, any unsuspected open case lying in the general wards of a hospital is a potential danger. Some would argue that these could be discovered by routine sputum tests instead of by routine radiological examinations, but this would throw an insupportable extra burden on the laboratories. Had only routine sputum tests been carried out, the 14 with positive X-ray findings but negative sputa would have been missed, since the majority were without symptoms and pathologically quiescent. Moreover, an active tuberculous lesion may be associated with no sputum or negative sputum; and those who maintain that such a lesion should be recognised in a surgical ward solely by routine clinical examination ' flatter their surgical colleagues, perhaps because their own line of work no longer puts them to such a test.

The only solution to this problem is routine X-ray examination of all admissions, and for economy this should be with the miniature apparatus.

Department of Surgery,
University of Birmingham. F. A. R. STAMMERS.

SIR,—Dr. Donald Court quotes my findings, which you published in a letter in 1943, on the health of 59 tuberculous nurses whom I had been following up. I am now able to add some further details about the same group, and to compare their position in 1942 with their state today:

	1942		*1949*	
Dead	8		14	
Ill (at home or in hospital) ..	18		1	
Working in hospitals	4	17 nursing	2	12 working
Working in sanatoria	13		8	
Private nursing	—		1	
Nursing in convalescent home..	—		1	
Working, but not nursing ..	1		3	
At home not working	8		14	
Lost sight of	7	(3 probably dead)	15	(3 probably dead)
Total	59		59	

It will be seen that 6 more are known to have died, and there may have been other deaths among the 15 whom I have not been able to trace. Only 15 are now working, as against 18 in 1942. Of 14 at home, not working, 2 are married and well, 4 (of whom 3 are married) are semi-invalids, and 5 are living with their parents and helping in the house.

Between 1943 and 1947 I collected information about a further 80 nurses. I have lost sight of 31 of these; but, of the remaining 49, 8 are dead, 4 are ill in sanatoria or at home, 8 are at home not well, 3 are married and not well, 3 are married and well, 16 are nursing full-time (11 in sanatoria, 5 in hospitals), 3 are nursing part-time (1 in a sanatorium, 2 in hospitals), and 4 are working but not nursing. No figures have been published about this group before.

London, S.W.6. E. D. Andrews.

MEMORIAL TO SIR JOHN FRASER

Sɪʀ,—Some months ago you granted us the courtesy of your columns to announce the opening of a fund to establish a memorial to the late Sir John Fraser, formerly regius professor of clinical surgery and principal of Edinburgh University. It is our intention to close the fund on Dec. 3, and those who may still wish to contribute are reminded that subscriptions should be sent before that date to the treasurer, Mr. John Bruce, F.R.C.S.E., at the Department of Surgery, the University New Buildings, Edinburgh.

Edward V. Appleton
James M. Graham
Frank E. Jardine
James Learmonth.

VACANCIES ON MANAGEMENT COMMITTEES

Sɪʀ,—In your issues of Nov. 12 (p. 922) and Nov. 19 (p. 951) you draw attention to a circular on this subject issued by the Ministry of Health.

There is one important interest of the community which is commonly overlooked in the constitution of management committees. I refer to hospital matrons, who, as a group, comprise women of intelligence and integrity with as important a contribution to make to the administration of hospital services as have medical men. In fact, there is scarcely any aspect of hospital organisation on which a matron has not got a point of view worth hearing. Some management committees invite a matron to attend and to express an opinion; but she has no voting power. Many will say that the vote is not important, but I believe that its absence is an insult to a group that comprises many great women. Some management committees merely invite a matron to attend when something of particular interest to her is being discussed. This is absurd; for who is able to decide what is, and what is not, of interest to a matron?

I know that I shall be told that hospital matrons are being encouraged to take part in the work of the house committees. This obviously is not enough. Moreover, the argument that matrons cannot take part fully in the business of management committees because they are paid officers of the committees is one which should be eliminated as in the case of medical staffs. Certainly the matron of every hospital with over a hundred beds, even if she is appointed by the management
should be regarded as a direct employee of the
board. These matrons should be represented
inclusion of one in the membership of each
committee.

Exeter. Norman Ca

THE DUMPING SYNDROME

Sɪʀ,—After reading your correspondent's acco
his disability (Nov. 12, p. 907), I imagine tha
conscientious practitioner will think twice before p
his ulcer patients in the hands of a surgeon.
patient has indeed endured a regrettable series o
fortunes, and I sympathise with his wish that h
retained his ulcer and his stomach—a sentime
doubt echoed by his surgeon.

There has lately been a good deal of interest
dumping syndrome; and whatever its mech
I am sure that its frequency has been exaggerat
cannot agree that this complication affects a con
able proportion of gastrectomised patients, and I s
that the severe grade experienced by the writer is
uncommon; certainly we have not seen an ex
in the last couple of hundred resections carried
this unit. It would be wrong to allow i
albeit unfortunate—experience to darken the
of an operation which, in hands accustomed
performance, is as safe as any comparable proc
and which has so many benefits to offer. In my e
ence chronic ulcer cases submitted to partial gastrec
are most grateful patients, and I regard it fro
points of view as one of the more satisfactory opera
in surgery.

West Middlesex Hospital, Isleworth. Louis A. I

CONTROL OF TUBERCULOSIS

Sɪʀ,—I have read with interest the varying poi
view expressed on this subject, and am a little dism
at the gulf which appears to be fixed between
sanatorium doctor and chest physician.

Surely Dr. Caldwell (Nov. 12, p. 910) has got t
root of the problem by emphasising the necessit
the chest physician to have charge of the patient
notification right through to rehabilitation. If all
physicians cannot yet have their own beds, they sh
at least have control of admissions to blocks of
in the various institutions where their patients
treated, a proportion of the beds of each type b
allocated to each clinic within the region. Only a s
proportion of the total beds need then be reserved
filling by the regional board. By keeping consta
under review his own waiting-list, the chest physi
could adjust the relative priorities for hospital admis
which change almost daily. Better use would the
made of the limited number of beds, and with pers
control of his waiting-list the clinic physician w
be careful not to block beds by admitting a pat
to the wrong type of institution. Too often, by
time a patient is admitted his condition has chan
radically for better or worse, and it has now bec
notoriously difficult to arrange transfers from
hospital or sanatorium to another, even within
same region.

If carefully supervised, the enforced period of wait
need not necessarily cause great harm to the patie
nearly all will benefit from a preliminary period of st
bed rest, which can often be made possible by the c
certed effort of the chest physician's team. Po-tu
reduction of cavitating disease may be gratifyin
successful when carried out at home under close sup
vision, and pneumoperitoneum is an innocuous fo
of mechanical treatment which may help in controll
acute disease. It is, of course, important that the ch
physician should be enabled to admit patients for 48 hou

phrenic crush, and also for bronchoscopy—an tigation without which rational treatment often ot be planned.

. Jeanes (Oct. 29) doubts the possibility of giving tomycin at home. In this area it is done success- . in suitable cases, by the district nurse giving tions of 1 g. daily for 6–8 weeks, a course of para-osalicylic acid being administered concurrently e hope of delaying streptomycin resistance.

th adequate rest some patients will improve to a i-ing extent, and hospital treatment can be post-d or even avoided. Others will improve so much me that they become treatable by collapse therapy dmission to hospital, provided that by juggling his waiting-list the supervising physician can ge admission to hospital at the right moment. there will be those whose progressive disease and of resistance, poor home conditions or difficult erament make hospital treatment a matter of grave cy. Yet such patients may have to wait many ts for admission and may become untreatable. beds are cluttered up with chronic or hopeless which would do just as well, or as badly, at home.

tile admiring the courage of those who induce mothoraces in the home I feel that unless general itals immediately open 5% of their beds to cases of onary tuberculosis, the only possible solution e present bed shortage is the acceptance by sana-m physicians of a shorter term of stay for their nts. Rather than strive by prolonged sana-m treatment to render the disease of a few inactive. bmit that, as a short-term policy, we should aim aking the greatest possible number of persons sputum-tive, and leave convalescence where possible to the of the chest physician. More use might also be e of outdoor shelters for chronic open cases, and authorities could help to solve the problem of the growing band of "Homeless Hectors" by the ision of hostels and night sanatoria.

e tuberculosis physician has a great task and t opportunities. The value of his work to the munity has been recognised by the conferring of ialist and consultant status and the provision of far er facilities than ever before. In his aim of con-ing tuberculosis by finding and treating or isolating active cases, and employing general hygienic and ific prophylactic measures, he is assisted by a large n which includes the family doctor, thoracic surgeon, ical officer of health, tuberculosis health visitor, rict nurse, home-help supervisor, children's officer, sing manager, occupational and vocational therapist, disablement rehabilitation officer. If the members his team work together with a will, theirs, in the end, be the victory.

Southend-on-Sea.

E. G. SITA-LUMSDEN.

IR,—In the recent correspondence on this subject, the ous writers were mostly concerned with the manage-t of cases amenable to treatment. No mention has n made of the advanced cases, for which, because the shortage of beds, sanatorium treatment is not templated.

n most areas a priority system of admission to atorium operates, and of course medical superinten-its do not like to see their beds blocked with cases which very little can be done. It is forgotten that, t at home, the advanced cases are most dangerous a source of infection. Any chest physician could e countless examples of contact infection due to se people being left at home in unsuitable surroundings, len they should have been in hospital. Here again e shortage of beds operates, but this could be overcome using some of the infectious-diseases hospitals for this purpose. For instance, in one area, where there are three such hospitals in a five-mile radius, the average daily occupancy of beds in 1948 was as follows:

Hospital	*Bed complement*	*Average occupancy*
A	36	10
B	32	3
C	30	4

These hospitals are usually fully staffed, and no greater skill is required in nursing tuberculosis than other infectious diseases. With a little equipment these hospitals could admit, under the care of the chest physician, early as well as advanced cases. In this way, the number of early cases on sanatorium waiting-lists would be reduced, and they could admit a greater proportion of advanced cases.

I am well aware that this is not an ideal arrangement, but it is certainly better than leaving the patient in a home where very few or no precautions are taken, or can be taken, against the spread of infection.

Newcastle-on-Tyne.

WILLIAM ROZNER.

SIR,—The greatest immediate problem regarding tuberculosis in the U.K. is the shortage of sanatorium beds.

A Ministry of Health statement (March, 1949) declares: "The reason for this is not the lack of sufficient accommodation but the persisting shortage of nurses." Many of the empty beds could be used by the further dilution of present nursing resources, as suggested by Dr. Bentley [1]; by a greater use of patient help; and by the affiliation of general training schools for nurses with sanatoria. Such affiliation should enable every trainee to have three months' experience, unobtainable elsewhere, of the most important disease affecting young adults.

The Ministry's statement overlooks, however, the basic fact that in the U.K., compared with other countries with high standards of public health, there is a great and absolute insufficiency of beds. The following table, giving approximate figures for 1948, is interesting in this respect:

Area	*Population, millions*	*Tuberculosis Death-rate per 100,000 (all forms)*	*Tuberculosis Ratio of beds to total deaths*
Denmark	4·0	25·0	5 : 1
Holland	9·5	28 0	3 : 1
U.S.A.	143·4	30·0	3 : 1
Canada	12·9	37·1	3 : 1
Ontario, Canada	4·3	19·2	4 : 1
England and Wales	41·6	52 9	Staffed—1·3 : 1 If fully staffed—1·6 : 1

The ratio for Holland does not include over 400 beds in Switzerland, fully or partially subsidised. Belgium, whose bed problem at home is the same as that of the U.K., subsidises, partly or fully, about 780 beds in Switzerland. Although £5 million was allowed for tourists to come to Switzerland this year, the U.K., with its much greater population and tuberculosis problem, does not use, officially or semi-officially, treatment facilities in Switzerland.

In September I visited Leysin and Davos. I found there were, mostly in these two centres, 1000 empty beds which can be staffed. If only half of these were occupied by British patients, each for an average of six months, 1000 more patients a year could receive sanatorium treatment without delay. But, as the pound sterling has less than half of its 1930 exchange value in this country, the subsidies, which used to be paid by many local authorities for private treatment in Switzerland, would have to be restored. Such subsidies could be based, as they were before July, 1948, on the cost of treatment in the U.K., and suitable patients selected by the regional medical specialists.

Among the quarter of a million people suffering from active tuberculosis in the U.K., there must be at least

---

1. Bentley, F. J. *Lancet*, 1948, i, 722.

five hundred who, with the help of these grants, could afford sanatorium treatment in Switzerland. If 500 beds were occupied continuously, the total amount of hard currency involved would be less than £450,000 in one year, of which about half would come from public funds. The new health Act, which is supposed to provide "free treatment for all," handicaps the tuberculous patient, who could formerly, with the help of the subsidies, receive immediate treatment in a private sanatorium.

Since the Ministry of Health cannot provide treatment, except after long delays, the grants should be restored to enable some patients to arrange their own private treatment.

Montana Hall, Montana,
Switzerland. HILARY ROCHE.

BEDSIDE LOCKERS

SIR,—I have read with considerable interest, and no little amusement, your leading article of Oct. 22 on the draft British standard for hospital bedside lockers. But while I respect your views, I am bound to say that in framing them you seem to have fallen into the common error of supposing that all that is needed to design a locker (or indeed, anything else) is "a little commonsense." If it were not for the eccentric ideas of these designers, your argument seems to say, it would be the simplest thing in the world to construct a locker which would meet all the requirements and satisfy everybody.

In fact, of course, it is well known that there is no sort of agreement on this matter among the different hospital authorities. So the problem becomes one of reconciling many divergent opinions by the introduction of a few obviously desirable improvements, and for the rest leaving the individual hospital free to express its own ideas.

Not having served on the B.S.I's. committee, I cannot say with what ideas they may have embarked on their inquiries; but it seems fairly clear from their conclusions that they very quickly gave up any hope of arriving at the "ideal" hospital locker. Instead, they have wisely limited their recommendations to those particular points of design and construction about which some useful measure of agreement could be found to exist. When they say, therefore, that "compartments with doors are preferable to drawers," they do not deny the usefulness of drawers, but merely point out that a majority of hospital authorities prefer compartments. Similarly with the decision to discourage the provision of urine-bottle compartments. For the rest, they have sensibly left a wide measure of choice to the individual hospital, concentrating their attention on such indisputable considerations as the need for sturdy construction, mobility, and heat-resisting surfaces.

Development Ltd.,
26, Albemarle Street, London, W.1. FRANK MORTIMER.

PRINCESS TSAHAI MEMORIAL HOSPITAL

SIR,—May I appeal to your readers for contributions towards the funds of this hospital?

When the Emperor of Ethiopia, Haile Selassie, was driven from his country by the armies of Mussolini, Princess Tsahai, a girl of 17, came into exile in Britain, and at once sought work as a probationer nurse, so that she might be able to serve one of her country's greatest needs when liberation came. She was not very strong, and a nurse's training is hard, but she had all the qualities of a good children's nurse: her matron wrote: "Guy's Hospital will remember her as one of whom it will always be proud." She was at Guy's when it was bombed during the war.

Ethiopia was liberated, and Princess Tsahai returned to her country, after five years' service as a nurse in Britain, to find friends and relatives dead, thousands of homeless, maimed, and wounded, and thousands of orphaned children thronging the streets. She opened a home for the orphans, clinics, and dressing-stations, giving her knowledge and all her strength to the service of the sufferers. Then she married, and went with her husband to a remote district, where she at once opened a dressing-station, and had dreams of a but, working too hard, she was struck down and died age of 22, lacking the skilled help she had devoted bringing to others.

It was to commemorate her life that some of us build a hospital in Addis Ababa to her memory—a with wards for children and maternity, and with for teaching and training.

We set out to raise £100,000, and have so far £85,000. The hospital is built and partly equipped; we want £15,000 to complete the enterprise. Those who will be doing something to show in a foreign and backw country that the English-speaking race believes in m pity, and loving-kindness—the qualities of which a hos is the finest possible outward and visible sign.

Donations should be sent to the hon. treasu Lord Horder and Lord Amulree, c/o Messrs. Gould Prideaux, 88, Bishopsgate, London, E.C.2, the hono accountants, who will gratefully acknowledge receip

WINST
Chairma

REGISTRARS

SIR,—As a registrar with experience in a hospitals, I wish to thank you for your leading last week. I would, however, like to add to what been said.

There seems no doubt that the cash value of em ments is going to be raised. Two principles, I th need stating:

1. The cash value of emoluments should not be more the actual cost to the hospital of the services provided. not think that hospitals are justified in making a profi of registrars.

2. There should be no sliding-scale of emoluments depe on the income of the registrar. A man can only be exp to pay for what he gets, and not for what he theoret might be expected to get. In one hospital it has suggested that a resident registrar should pay £170 a for his board and lodging. This is 27*s.* a week more t houseman pays, and it is not possible in this part hospital to find accommodation which would justify difference. In another hospital a registrar is being ask pay more for a bed-sitting room and his meals in the do dining-room than the matron is charged for a flat an meals brought to her.

Emoluments are important, but more important are a registrar's prospects. The crux of this probl consultant establishments, for on the work and resp bilities demanded of a consultant depend the nu of registrars and the responsibility they are exp to take. If a consultant is responsible for too beds, his registrars will in effect be doing const work without the status of pay. Furthermore, s consultant will probably have to have more regi under him than a consultant with less responsib These registrars will be working under a double disa as they will also be lowering their overall chances consultant post.

There is at present, when selecting registrar consultant posts, a very definite prejudice ag registrars from ex-local-authority hospitals. Regis in these hospitals, even when the bed: consultant is reasonable, nearly always take greater and arduous responsibilities than registrars of an equiv grade in other types of hospitals, particularly tea hospitals. Their practical experience in both cl and social problems is, because of their work, al always greater and better balanced than that of who have not stirred from a teaching hospital. standard of work in many ex-local-authority hos is very high, despite difficulties comparatively unk in teaching and ex-voluntary hospitals. Nevertl registrars in ex-local-authority hospitals are at a disadvantage when competing for consultant probably because they do not know the right pe his disadvantage is made even more unjust by the sively high bed : consultant ratio that is nearly rs found in these hospitals.

is issue of bed : consultant ratio has not yet been . Why, for example, is a full-time physician ted to be responsible in one area for 400 beds, in er for 150, and in yet another for 60 ? I can vouch ese figures. Until there is some generally accepted ard for consultant establishments there is no hope easonable consultant : registrar ratio or of reason- prospects for registrars. Unless something is done the results of the present situation will be disastrous oth the public and the profession, and the cleavage een the ex-local-authority and ex-voluntary hospitals greater than in the past.

Eicoi.

CURARE AND PRECIPITATE LABOUR

—Why does Dr. Rollason, in the case reported im last week, attribute the increase in uterine tone finitely to curare ? It was not the only drug em- ed. What other effect upon uterine tone is to be cted, for instance, from 10% cyclopropane, which also administered ?

Forest. MICHAEL D. NOSWORTHY.

MEDICAL BIOPSIES

—In your annotation under this heading last week id : " Of late years great strides have been made in techniques of aspiration, or needle, biopsy." What, may I ask is a " medical biopsy " ; what are we to ine that an " aspiration, or needle, biopsy " can be ; wherever are we to find these " great strides in niques " ?

it possible that you assume that had Shylock been to secure hæmostasis he would have performed a biopsy," or is your distinction merely one of dress reby the excision of a lymph-node by a doctor in shirtsleeves is medical, but if he puts on his " full ative panoply " (or takes reasonable aseptic pre- ions) it is surgical ? Have such great technical strides made that we can now see with the eye of a needle ? perhaps we need not yet despair of the aspirations he camel.

o Sir ! Biopsies are examinations of the living, as necropsies are examinations of the dead, and usually made by pathologists, often with the help of roscopes. Pieces of tissue are being removed more uently from tumours, bone-marrow, liver, and spleen biopsy with a resulting valuable increase in diagnostic ision. The development of a few gadgets for this pose, however, hardly constitutes " great strides in niques." The editorial blue pencil should be employed help us maintain both a sense of proportion and a ard for the meaning of words.

yal Cancer Hospital,
London, S.W.3.

D. W. SMITHERS.

* Professor Smithers exposes a deficiency in the tor's vocabulary. By usage the " medical treatment peptic ulcer " has a limited connotation, and none ld suppose that by this was meant medical, as posed to lay, treatment. In the present instance any biguity in the title is surely dispelled by the opening tence of the annotation, which Professor Smithers otes. Just one of the " gadgets " to which he refers caused radical change in our conception of the galoblastic anæmias. We fully agree with our respondent, however, that all biopsies are less medical d surgical than pathological.—ED. L.

THE DOCTOR'S CREED

The concluding letters in this correspondence will pear next week.

Parliament

New Clauses to Amending Bill

WHEN this Bill was considered in committee in the House of Lords on Nov. 17, Lord SHEPHERD moved the new clauses tabled by the Government.[1] The purpose of the first, he explained, was to add to the authority of the Medical Practices Committee. At present its functions were limited technically to granting applications by doctors not yet on a medical list, for inclusion in that list. But it was important that the committee should have authority to look at all applicants. For instance, when a doctor on the list desired to appoint an assistant and the executive council for his area refused the appointment the doctor should be able to appeal to the Medical Practices Committee. The second clause, giving statutory authority for the proposal to make a charge for prescriptions, was drafted, Lord Shepherd pointed out, in general terms because the exact nature of the arrangements to be made had not yet been settled. But the charge would not exceed 1s. and old-age pensioners would be exempt. War pensioners would continue to receive free treatment for their pensioned disabilities. The object of the amendment was twofold : it was to act as a deterrent to excessive or unnecessary resort to doctors and chemists, and to reduce expenditure. Eventually it might be possible to tackle these problems on other lines. The Central and Scottish Health Services Councils had set up a joint committee to advise whether it was desirable and practicable to restrict or discourage doctors from prescribing medicines of doubtful value or of unethical character, and unnecessarily expensive brands of standard drugs. The joint committee consisted of members suggested by the Standing Medical and Pharmaceutical Advisory Committees of England and Wales, the Scottish Medical, Pharmaceutical, and General Practitioner Services Advisory Committees, the three Royal Colleges, the Scottish Royal Medical Corporations, the British Medical Association, the British Pharmacopœia Commission, and the Society of Apothecaries. It was too early to say what might be found possible on these lines, but it was conceivable that general acceptance of a list of drugs of recognised value, with the corollary that a doctor would be expected to justify the prescribing of any not so recognised or of unnecessarily expensive brands of recognised drugs, would in the long run be the better way of handling the problem. The clause was permissive and would enable the Minister to vary conditions governing these practices.

Lord LLEWELLIN asked for an explanation of the term " unethical " medicine. The powers given under the clause were wide and the regulations would have to be watched when they were issued. He did not know whether the line of 1s. per prescription would work in practice. He was told that 70% of the prescriptions made under the National Health Service were not handled by the pricing-bureau, and if there was to be a charge of 1s. for every prescription a much larger staff would be needed in the pricing-bureau, unless the intention was to make an average adjustment, as apparently had been done so far under the Health Acts. Was the price to be per prescription or per item on the prescription ? He urged that some provision should be made for people who had to take a drug, such as insulin, regularly. Lord SHEPHERD said he hoped the regulations would be issued before long. Of course there would have to be consultations about them. Not only would the question of prescribing be reviewed by the joint committee, but there would also be consultation with the professional organisations about the details of the scheme for the recovery of charges. He admitted the difficulty of interpreting " unethical medicine " but tentatively suggested that unethical treatment by the supply of drugs appeared to be something that stimulated the emotions. As to Lord Llewellin's statement that 70% of the prescriptions were not handled by the pricing-bureau, an attempt was being made to secure a fairly inexpensive administrative system. The point about the repetition of prescriptions for a given complaint would receive consideration.

---

[1] See *Lancet*, Nov. 19, p. 968.

Finally Lord Shepherd moved the third new clause giving power to make regulations to charge for any use made of the National Health Service by people not ordinarily resident in this country. He said that reasonable use of our health services by those who fall ill when visiting this country was, in the Minister's view, a part of hospitality; but abuse by people who perhaps came here mainly to take advantage of a free service for which we had to foot the bill, was quite another matter. This clause was meant as a power to check abuse.

QUESTION TIME

Medical Education

Mr. **Somerville Hastings** asked the Minister of Education to what extent suitability for the profession, as apart from scholastic attainments, are taken into consideration in selecting students for scholarships and maintenance grants for training for the medical profession; and what steps were taken to assess this.—Mr. **George Tomlinson** replied: The assessment of suitability of candidates for the medical profession is mainly a matter for the medical schools, acceptance by which is one of the conditions of an award by my department or local education authorities.

Mr. **Hastings**: How many medical students are now in receipt of scholarships and maintenance grants provided by the State and local authorities, respectively, in England and Wales; and how many were in receipt of similar awards in 1938?—Mr. **Tomlinson** replied: At present 3071 awards by my department to medical students are current, of which 2634 are under the Further Education and Training Scheme. The comparable figure for 1938 was 29, all of which were State scholarships. I am unable to state how many of the awards by local education authorities are for medical students.

Mr. **Hastings**: What is the cost of medical education in England and Wales borne by your department?—Mr. **Tomlinson** replied: The expenditure on medical education falling on my department is confined to awards to students. The estimated cost in the current year of awards made direct by the department is about £814,000. A substantial part of the expenditure by local education authorities on their awards to medical students is met by my department, but figures of this expenditure are not available.

Cost of Prescriptions

Dr. A. D. D. **Broughton** asked the Minister of Health what was the average cost of National Health Service prescriptions; how much of that amount was dispensing fee; and how much the cost of container.—Mr. **Aneurin Bevan** replied: The average cost of National Health Service prescriptions in England and Wales is at present about 3*s*. Of that amount 1*s*. ½*d*. represents the average dispensing fee and 1½*d*. the average cost of containers.

Mr. **William Gallacher** asked the Minister what consultations had taken place between him and representatives of the pharmaceutical industry in order to see how prices could be lowered to lessen the charge of prescriptions.—Mr. **Bevan** replied: The prices to be paid for drugs supplied on National Health Service prescriptions are agreed between my department and the Central National Health Service (Chemist Contractors) Committee and are reviewed monthly. Significant reductions have been obtained in certain fields.

Mr. **Gallacher**: In view of the very great rate of profit made on some of these medicines would the Minister consider publishing a statement giving in detail the cost of various popular medicines and the profits being made out of them?—Mr. **Bevan**: I would not have the information.

Mr. F. W. **Skinnard** asked the Minister what percentage of the prescription forms dealt with by the pharmaceutical pricing-bureaux carried a single prescription, and what percentage more than two.—Mr. **Bevan** replied: Precise data are not available. Evidence before me suggests that the average percentages are about 60% and a little under 10% respectively.

Dispensing by Doctors

Mr. **Skinnard** asked the Minister what proportion of medicines prescribed under the National Health Service was dispensed by doctors.—Mr. **Bevan** replied: No precise information is available, but the estimated proportion supplied by doctors under part IV of the National Health Service Act is a tenth.

Dentists in the N.H.S.

Dr. **Broughton** asked the Minister what was the n dentists serving in the National Health Service on J 1948; and what was the latest available figure.—Mr. replied: 4562 and (on Oct. 1, 1949) 9468.

Hospital Accommodation

In answering a question on this subject Mr. **Bevan** that it was not intended to make any reduction in the c programme of the health service.

Calorific Value of Prison Diets

Mr. J. A. **Boyd-Carpenter** asked the Home Sec if he would state the average daily caloric value of th consumed at the latest convenient date by the inmates Majesty's prison, specifying any differences that there be in the cases of different classes of prisoners.—Mr. C **Ede** replied: The over-all average calorific value of diets on Nov. 8, 1949, was 3192. Particulars for the v classes are given as follows:

Local Prisons	Men	3126
	Women	3015
Regional and Central Prisons ..	Men	3438
	Women	301
Young prisoners	Boys	[illegible]
	Girls	31

A Second Opinion

Dr. A. D. D. **Broughton** asked the Minister of Insurance what persons were empowered by his to refer cases to regional medical officers for a second opinion.—Mr. **James Griffiths** replied: The empower me to require sickness benefit claimants to examination for a second medical opinion. The local manager refers the cases selected to a senior medical of the health department who consults the patient' doctor when deciding whether a case should go to the medical officer. The patient's doctor is invited to be at any examination. Dr. **Broughton**: Is the aware that some medical practitioners would like to to refer some of their own patients to regional medical for a second opinion on diagnosis and treatment, and discuss this matter with the Minister of Health with to making simple arrangements whereby general n practitioners may refer cases in that way?

Mr. **Griffiths**: Some of the general practitioners d cases to the regional medical officer, and that is a p which we seek to encourage on every possible occasion

Unstaffed Hospital Beds in Scotland

Mr. **William Gallacher** asked the Secretary of for Scotland what was the number of unstaffed hospita in Scotland at the latest available date.—Mr. A **Woodburn**: At Sept. 30, 1949, the number was esti at 6500.

Supply of Contraceptives to Soldiers

Mr. **Emrys Hughes** asked the Secretary of State fo what were the regulations dealing with the supply of c ceptives to soldiers.—Mr. **Emanuel Shinwell** re In overseas commands, condoms are made available free issue, to individuals who ask for them, with a v the prevention of venereal disease. In the United Kin where the risk of contracting venereal disease is consid less, no contraceptives are issued.

Anti-leprosy Measures in West Africa

In answer to a question Mr. A. **Creech Jones**, sec of State for the Colonies, stated that in Nigeria ther a fully organised leprosy service and arrangements were made to extend its activities from the areas in the sou the whole territory. Missionary bodies, already exten engaged in leprosy work, were being brought fully int programme. An experienced leprosy research office recently been appointed to the government service. A prehensive scheme for the future had been drafted an now under consideration.

Birth-control Advice in Nigerian Hospitals

Mr. N. R. **Sorensen** asked the Minister if consid had been given to the question of allowing birth c advice to be given at appropriate hospitals and clin Nigeria similar to the circumstances where this advic given through public medical authorities in this count Mr. **Creech Jones** replied: So far as I am aware, no.

Obituary

THOMAS PORTER McMURRAY

C.B.E., M.CH. R.U.I., F.R.C.S.E.

fessor McMurray, who retired last year from the of orthopædic surgery in the University of Liver- died from a heart attack in London on Nov. 16. as on his way to South Africa where he was to is son.

n in Belfast, the son of Samuel McMurray, he educated there at the Royal Academy and the 's University, where he graduated M.B. in 1910. h he thus lacked Liverpudlian birth and breeding, nt to Liverpool the year after he qualified, to work Robert Jones, and thereafter he carried on onservative tradition of the Liverpool school of pædics with almost native tenacity.

[Bacon & Sons

1911 he took up his appointment as house-surgeon e Royal Southern Hospital, where he afterwards became surgical tutor and registrar and later full surgeon. He was closely associated with Robert Jones in his work for children, and he joined the staffs of the Royal Liverpool Children's Hospital and the Alder Hey Children's Hospital, as well as the David Lewis Northern Hospital. He was also consultant orthopædic surgeon to the Lancashire County Council. During the 1914–18 war he was surgeon to the Military Orthopædic Hospital at Alder Hey and acted as inspector of orthopædic hospitals in Ireland. In 1919 he proceeded to his M.CH. degree and in 1926 he took his F.R.C.S.E.

McMurray as a surgeon a colleague writes: "He a superb artist. Rapid and precise, he often used y 'Don't mess about; go in, do what you want , and get out again.' As he got older he operated and less, and he made a point of saying that the for operating grew less as the surgeon grew older. ed, he was essentially conservative: he made no r change in method or practice, and in the last ty years he never used screws or nails or plates. examination of patients, whether in hospital or ulting-room, was brief and to the point. He wasted ime, gave his opinion confidently and succinctly, cheered the patient with some short, snappy sentence 'Go home and use it.' 'We will fix it for you,' You're a credit to us.' He could be as brusque and utspoken as Hugh Owen Thomas, as charming and as Robert Jones. At heart he was sensitive, disliking ence and pomposity, full of contempt for fashions eatment. He had a imp of mischief which popped from time to time, and he enjoyed good-natured er."

r many years before his appointment to the chair 940 McMurray had been lecturer at the university, many surgeons, in the Dominions as well as in ll remember his teaching with gratitude ; for, like Robert Jones, he had the wing young men to him and moulding . He trained scores of orthopædic surgeons, shep- ded them afterwards, and secured posts for many. "boys" are scattered all over the globe, and they rned to him whenever they came back to England. his disciples he gave the things that cannot be learnt m books or even from personal experience. He ested formality and scorned academic teaching. The dent was the apprentice whose natural place was h the patients in clinics and in wards. One of them alls his friendly warnings: "You have read that in ook" he would say reprovingly. "Seal it laddie"; d "Don't touch it laddie" were other characteristic ngs which have become traditional. He never ght to impress students but only to enlighten them. re than anything he delighted in leading them up the garden path, for he knew that then they would never forget the point at issue. Probably the deepest and most moving joy of his professional career came when his old students, at the dinner they gave in his honour, told him how much they owed to him over the quarter century which ended with his retirement from his chair last year.

During the late war, besides doing invaluable work for the Emergency Medical Service as orthopædic consultant in the North, he undertook the organisation of special courses of instruction in traumatic surgery. His gift of leadership and his constant anxiety to help the younger men was also apparent when, early in the war, he became president of the British Orthopædic Association. A fellow member writes: "Many, I think, must have been as impressed as I was by the masterly way in which he summed up a discussion, so that the younger members of the audience should receive a maximum of sound and useful information." Very many will miss Professor McMurray at next year's Liverpool meeting of the British Medical Association, of which he was president elect.

R. W.-J. writes: "The suddenness with which the alert vitality and boyish good humour of T. P. McMurray has been lost is still difficult to believe. Only in recent months he was still teaching postgraduate students from Australia, Canada, South Africa, and many other parts of the world. His teaching was forceful and dogmatic: and in so far as Liverpool traditions were concerned almost intolerant. Only last week, when the Hugh Owen Thomas lecture was delivered in Liverpool, he welcomed back to the fold 'a lost sheep,' who reaffirmed principles taught by the founder of British orthopædic surgery. But the memory that is preserved by former students is that of a quick-witted, good-humoured kindliness warmed by an emotion amounting almost to sentimentality which McMurray himself would never have admitted. Young surgeons throughout the world will long remember his clinical skill and astonishing dexterity, his stimulating teaching, and above all his capacity for kindness and deep affection."

Outside Liverpool McMurray also inspired respect and affection, and N. C. adds: "His influence has been profound, and not least upon those who, like myself, were critical of some of the minor details of practice which he maintained. It was, however, upon fundamental ideas that he succeeded, and he never ceased to teach the dominant doctrine of Thomas and the first principle of orthopædics, physiological rest. In emphasising conservatism, he nevertheless contributed to the advancement of surgical practice. *Characteristically he took* to himself little credit for the operations that go by his name. He preferred to acknowledge Lorenz as the originator of the osteotomy, which, as used by McMurray, is probably the best method of treatment for the un-united femoral neck fracture. The other variant for osteoarthritis of the hip was of particular value in correcting the element of deformity, but McMurray did not believe that it provided the ideal solution. His teaching was direct and practical. His own literary work was not voluminous, but he often contributed to scientific discussions and always with something worth hearing. His writings on the surgery of the hip and knee joints, on the problems of slowly uniting fractures, and on rehabilitation *are characteristic. He wrote one of the best little* textbooks on orthopædic surgery. McMurray was an apostle of orthodoxy based upon recognition of the importance to orthopædics of the biological processes of growth and repair."

For his retirement McMurray had bought Ystrad Cottage at Denbigh, where he enjoyed welcoming his friends. "He carefully spelt the word Ystrad for you, and when you arrived, before you were allowed in the house, he would say 'Come and see the garden.' He would formally introduce you to the roses, and if it was the fruit season he would be concerned lest you had not brought a large enough basket to be filled with apples."

Professor McMurray's first wife, formerly Miss Dorothy Hill, died in 1936. In 1944 he married Miss Winefred Evershed, who survives him. He also leaves by his first marriage a daughter and a son who is practising orthopædics in South Africa.

Notes and News

MODIFIED RAPTURE

Mass Observation have surveyed the National Health Service in an engaging book.[1] "Do we really like it now we've got it?" is the theme; and doctors, before they open their lips to reply, should note that the answer was sought from patients as well. The doctors get their say, though, in a chapter contrasting the points of view of Dr. D and Dr. Y. "Dr. D is tall, thin, has a slight stoop and wears spectacles; he dresses carefully but conservatively in a dark suit and tie and an Anthony Eden hat." His partner, Dr. Y, is sturdy and slightly rotund. "He wears expensive well-cut suits and looks successful." Both doctors find flaws in the service, but their attitude to flaws is different. Readers will enjoy equating themselves with one if not the other. Then there is a very good chapter on a doctor's day, through which Mass Observation's investigator accompanied Dr. D, even though it entailed 14 hours of active service and a night call to top it off.

Patients too will find themselves in these pages—commenting on the service, summing up the doctors, pronouncing upon health. Their praise for what is good in the N.H.S. might be described as British praise, tempered with caustic. "Most people can find something they don't like about the new scheme," the report says; "but most of them approve it as a whole. And in the last resort, when all the vexations and all the irritations have been aired, this woman's comment remains unanswerable: 'I like it that you haven't got to pay.'" She was one of those who used to hesitate to call the doctor to her children because she had not always the money ready to pay him.

As for Ronald Searle's wildly droll drawings—the Naldrett Press should make us all their debtors by publishing them as Christmas cards for doctors. But why does no artist ever look to see what a stethoscope is like?

BRITISH MEDICAL STUDENTS' ASSOCIATION

The 8th annual meeting of this association was held in Edinburgh on Nov. 11–13. Among the subjects discussed was student health—a field in which the resources have been improved during the past year. The association has undertaken, together with the National Union of Students and other interested bodies, to investigate the possibility of arranging special facilities for tuberculous students whereby they may continue their studies as a form of occupational therapy under the supervision of a university and at the discretion of the physician in charge of the case. The work of the association on behalf of ex-Servicemen has been widely appreciated. Several anomalies in the administration of grants have been corrected, and the Ministry of Education has agreed to make a special concession in favour of medical students, and to continue some measure of financial support to the newly qualified ex-Service houseman who is supporting a family. The meeting appointed a grants secretary, who will be responsible not only for matters concerning ex-Service grants but also for advising students in receipt of other awards. It was noted that facilities for showing films are still inadequate at many schools. There is at present no adequate medical-film catalogue, and the association has set up a film-viewing panel to review medical films from the student's viewpoint. Very successful clinical conferences have been held at Cardiff, Manchester, Sheffield, and Glasgow; and it was decided to encourage the holding of conferences for preclinical students, thus stimulating the interest of students at all stages in the work of hospitals in other parts of the country.

P. L. C. Diggory, of University College Hospital, was elected president, and Jane Stanley Evans, of Cardiff, secretary, for 1949–50.

PUTTING THE PATIENT AT HIS EASE

Information leaflets for patients entering hospital are not easy to write. Some are fulsome yet convey little real concern for the patient's comfort. Some are cold and formal, looking to the patient like a string of discouraging rules. A leaflet from Tindal General Hospital, Aylesbury, neatly avoids these clashing rocks. It is plain, friendly, straightforward, and packed with useful facts.

"It is hoped," it begins sensibly, "that your stay in this hospital will be as comfortable as possible." The correct postal address of the hospital, its telephone numbers, the address of the hospital management committee, the names of the medical superintendent, the matron, and the trative officer follow. Then the patient is told the his ward, the sister in charge of it, the physician under whose care he will be (and he is told whether him Dr. or Mr.), and the house doctor who will day-to-day care. He is advised to ask the sister house doctor about medical or nursing problems, almoner about such things as certificates, transport, valescent homes. He is told what are visiting times, friends can get visiting cards, what to do about his clothing, and ration-book, when meals are served, and are the smoking and wireless hours. The times and plac religious services are given. The postal arrangement explained, the library service described, the visits of the dresser and chiropodist noted. He is invited to sha occupational therapy, to coöperate about teaching, and write and give nis comments when he gets home.

There is perhaps one small flaw in the admirable docum A letter, he is told, will in any case be sent to his doctor; if, at the time of discharge, he wants to know more about illness, he is "to approach the house doctor, who will d best to explain"; and if he wants further advice he sh ask the physician or surgeon under whose care he has b The morale of the patient seems here to be maintained at expense of that of the houseman—who, poor fellow evidently not got the hang of the case. Would it not b reassuring for all parties if the patient could be told th houseman would in any case explain his illness to him; that if he wanted further particulars the physician or su would always willingly answer questions?

RESCUE FROM DROWNING

A new type of life-saving gear for rescuing the drow consists of a long double-loop formed by a circular buoy cord divided in the centre with a sliding hitch forming divisions—one for the casualty, and the other for the resc The rescuer passes one loop over the shoulders to the che the casualty, presses the hitch close up, and then sw away with the other loop around his own chest an shoulders. In this way, it is claimed, the rescuer is left his arms and legs free. The equipment, designed by Cap Ernest Adams, is obtainable, under the name 'Life-L from Messrs. Siebe, Gorman & Co. Ltd., Neptune W Tolworth.

SUBSIDIA MEDICA

This new quarterly journal[1] of which the first issue app in September, is published under the direction of Aus specialists in pharmacology and related sciences. The aim is to provide information about new drugs, inclu their chemical structure, actions, and uses, side-effects, contra-indications, dosage, forms available, manufactu names, and official regulations concerned with their su and use in Austria. Reviews will be a prominent feat and mercurial diuretics are dealt with in this first num New apparatus and technical procedures are also descri The format is convenient and the typography excellent.

MEDICAL PROGRAMMES ON TELEVISION

In a television programme on Nov. 21, Dr. R. D. Lawr discussed the diagnosis and treatment of diabetes and P C. H. Best, F.R.S., was seen in a specially filmed interview. programme was one of a series designed to introduc layman to medical procedures. The first, on H Chemicals, was introduced by Sir Alexander Fle F.R.S.; and a programme on surgery is to be presented month.

These are not the first features of medical interest wh have been shown to Britain's growing television audi There have, for instance, been programmes on blo transfusion and mass radiography; these had rather obvi "propaganda" implications, and the response, particula to the latter, was considerable. Medical students and phy therapy students and staff took part in a production physiotherapy. The television microscope enables mi organisms to be televised direct, without the interventio film. Like other programmes, the Under the Micro series was not formally educative, but the field was cover a way which presupposed an intelligent audience; for programme the phase-contrast microscope was employ These programmes have been given in the evening—the p viewing period. Medical features of a more directly practi nature are included in the women's programmes in the on. Here there have been discussions and demon- as on feet, with particular reference to posture; on diet; on the treatment and prevention of burns and ; and on the care of a patient in bed. A number of films have been televised, such as those on mental which are being shown at present; and the work of the r and physiotherapist have been illustrated. It is hoped, ertain difficulties can be overcome, to include mother- emonstrations, and, as a further extension of the policy pagating positive-health ideals and helping to dispel include in the children's hour a feature on dentistry. , there has unfortunately not emerged a medical mality" on television comparable to the Radio Doctor, en neither was there a Radio Doctor in the Savoy Hill

---

[1] Meet Yourself at the Doctor's. London: The Naldrett Press. 1949. Pp. 70. 3s. 6d.

[1] *Subsidia Medica*. Published quarterly by the Verlag Hollinck, Vienna 3, Steingasse 25. Pp. 52. 6 Austrian sh

television programme must, of course, be not only but "entertaining." There are difficulties as well as unities in the medium, and it is encouraging that the rs at Alexandra Palace have not hesitated to show ative programmes, such as that on diabetes. The television authorities are always pleased to receive tions from doctors.

"HIS FIGHTING CHANCE"

s is a ten-minute sound film made for the Ministry of by the Crown Film Unit, and obtainable in 16 and from the Central Film Library. Largely made up of ial from last year's *Polio Diagnosis and Management*, lm is designed for showing in public cinemas; and oosevelt has recorded part of the commentary. Dealing with hospital care and reablement, it shows a baby young man at the beginning of their illness and at s later stages. It might usefully have explained some- of what happens to nerves and muscles in this illness; is nevertheless well made and conveys the importance ping up the patient's morale.

HOW TO EAT AND DRINK

o and wine are appropriately discussed at Christmas. ook[1] on these absorbing topics, Nell Heaton and André offer sound information, pleasant reading, and elegant tation, and awake a bitter-sweet nostalgia. André we know as the doyen of the wine trade in London, ent of the Food and Wine Society, and author of many s on wine, its production and uses. In this volume ites a concise and authoritative series of essays on wines spirituous liquors, setting out all that a hostess or sseur needs to know. Nell Heaton has captured the t in the high-class Mrs. Beeton-in-the-original type of and, as usual, manages to arouse an interest that rises e and beyond rationed foods. In addition she shows ty taste in quotation and introduces each month with ginal, brief, rhythmic piece of prose.

JEWELLERY AS A HANDICRAFT

CCUPATIONAL therapy so often ends up with an object h nobody wants—a rug which is (unintentionally) a little , a set of table-mats in unwelcome colours, a lot of g belts, or a set of paintings remarkable rather for their peutic effect on the patient than their æsthetic charm for amily. There is much to be said for teaching him, instead, ake simple ornaments of inexpensive materials which his and daughters can praise, and even wear for a time, ut being committed to a long association. Last year Worshipful Company of Goldsmiths arranged a conference[2] ch simple jewellery-making was discussed as a diversion people and convalescents. Mr. Claude Geoffroy- ume, who received a grant from the company to enable to demonstrate the craft to occupational therapists, has published an attractively illustrated book,[3] listing the s and equipment needed and giving directions for the ing of various little ornaments. It is written for the her rather than the student, and no tyro could expect to t up jewellery-making from this book without the help of structor, anyhow in the initial stages; or, indeed, without per equipment, for though the tools are described as le they are quite numerous and not all the sort which found in the family tool-chest. The book shows a design for a bench to be used on a bed; and with this, and a visiting instructor to guide him, any neat-handed person, man or woman, should be able to decorate his family to some tune. If he can ally himself to the hospital dramatic society and provide the ornaments for their costume pieces so much the better.

University of Cambridge

The degrees of M.B., B.CHIR. have been conferred by proxy on E. K. Westlake.

Dr. J. R. Robinson has been appointed assistant director of research in experimental medicine, and Mr. C. L. Smith, PH.D., physicist with special reference to the applications of high-voltage apparatus to radiotherapeutics.

University of London

Dr. E. W. Walls has been appointed to the S. A. Courtauld chair of anatomy at the Middlesex Hospital. The title of reader in anatomy has been conferred on Dr. Ruth Bowden in respect of her post at the Royal Free Hospital.

The degree of D.SC. has been conferred on Prof. K. J. Franklin.

The governing body of the British Postgraduate Medical Federation have appointed Brigadier D. C. Bowie, F.R.C.S.E., regional adviser in postgraduate medical education for the North West Metropolitan hospital region from Feb. 1, 1950.

The following have been recognised as teachers of the university:

T. A. B. Harris, anæsthetics, W. S. McConnell, anæsthetics, E. H. Rink, anæsthetics, T. H. Hills, radiology, Ralph Kauntze, medicine, R. S. Lawrie, surgery, T. L. T. Lewis, obstetrics and gynæcology, R. C. MacKeith, children's diseases, J. W. Mansie, dental surgery, T. A. Munro, mental diseases, all at Guy's Hospital; F. S. Cooksey, physical medicine, King's College Hospital; G. J. Cunningham, pathology, St. Bartholomew's Hospital; H. F. Anderson, surgery, D. C. Shields, physical medicine, St. George's Hospital; H. J. Wallace, dermatology, W. D. Wylie, anæsthetics, St. Thomas's Hospital; Henry McIlwain, biochemistry, Institute of Psychiatry; J. A. Fraser Roberts, hygiene and public health (medical genetics), R. F. Tredre, hygiene and public health (tropical hygiene), London School of Hygiene.

Royal College of Physicians

Prof. W. H. Wynn will deliver the Fitzpatrick lectures on Tuesday and Thursday, Dec. 6 and 8, at 5 P.M., at the college, Pall Mall East, S.W.1. Continuing the survey of Pestilence of War which he began last year, he will deal with the 6th to the 15th century in his first lecture, and the 16th to 19th century in his second.

Royal College of Obstetricians and Gynæcologists

At a recent examination for the diploma in obstetrics the following were successful:

Maksymilian Allerhand, Janet W. Anderson, Jerzy Arendt, Margaret A. Barber, G. T. D. Barr, P. R. Birks, Grace F. M. Braid, E. R. Broadberry, F. B. Bromfield, A. M. Buchanan, J. S. Caldwell, I. C. Campbell, J. E. Carrick, Helen A. Cawson, A. R. Cini, Patrick Coffey, M. I. Cookson, Janette G. Cowie, Mary Creevey, Margery N. Cummins, E. C. Davies, Margaret S. Dawe, A. M. Dawson, Binapani Dei, Christabel M. Dickie, E. M. Edwards, R. L. Edwards, M. W. Eddings, S. E. Ellison, James Elstub, R. N. M. Eminson, S. C. Farman, Margaret M. Ferguson, M. B. Flangan, Ammud Freier, William Gavin, G. S. Hargrave, R. T. T. Harrison, R. D. C. Hart, Brenda M. Hilton, Catherine M. Hoyle, B. W. Hughes, E. N. Hugh-Jones, R. C. Humphreys, Barrymore Humphries, Mary H. Hutcheon, Manjula Khaserao Jadhav, John James, R. J. Jameson, Alexander Jamieson, R. D. Johnstone, Barbara Jones, Artin Karnik Kantarjian, Thomas Kelly, H. A. Kelsey, Colette D. G. Le Doux, M. P. Lewis, Alistair Macarthur, I. M. G. Mackay, E. A. McColl, A. C. McDougall, I. D. Mackichan, C. A. Martin, Kazimierz Antoni Makos, G. C. Mathers, Stanley Mercer, T. J. M. Monteith, A. C. Malvaney, Amnah Sabri Murad, D. R. Murley, A. G. Murray, E. M. O'Dwyer, J. P. O'Dwyer, Mary G. O'Hare, R. A. O'Shea, R. L. Osmont, Margaret G. Oyston, R. A. O'G. Pearson, Alexander Persey, M. J. Peto, Sonia A. Purdie, Irene Rajaratnam, G. F. E. Ramsden, G. H. Rees, G. T. Salter, R. S. Saxton, R. T. Sears, T. B. Sherry, Mary A. Institute of Psychiatry

On Thursday, Dec. 1, Prof. W. E. Le Gros Clark, F.R.S., will lecture on the Visual System, and on Thursday, Dec. 8, on the So-called Rhinencephalon. Both lectures will take place at 4.30 P.M. at the Maudsley Hospital, Denmark Hill, London, S.E.5.

Bolton Royal Infirmary

On Thursday, Dec. 1, at 3.15 P.M., Dr. Harold Balme, medical officer in charge of rehabilitation at the Ministry of Health, will open the extensions to the department of physical medicine and rehabilitation at this hospital.

National Health Service Tribunal

The address of the clerk to this tribunal is now R. B. Cooke, Solicitor, 2, John Adam Street, Adelphi, London, W.C.2 (TEMple Bar 6055).

Research Board for the Correlation of Medical Science and Physical Education

The William Hyde Award (£300) for 1948, for work in connexion with physical medicine, has been given to Dr. J. M. Tanner, lecturer in physiology at St. Thomas's Hospital.

West of England and Wales Society of Dermatology

The inaugural meeting of this society was held at Bristol on Oct. 28 when Dr. Clifford Evans took the chair. It was decided to hold three clinical meetings each year—one will will be at Bristol in October, one in Wales in January, and one in Gloucester, Plymouth, or Exeter in April. Further information may be had from Dr. Robert Warin, the hon. secretary, 18, Mortimer Road, Clifton, Bristol, 8.

British Commonwealth and Empire Nurses War Memorial Fund

This fund was inaugurated by the *Nursing Mirror* in 1946 to furnish a memorial chapel in Westminster Abbey and to found postgraduate travelling scholarships for nurses and midwives. Over £70,000 has been subscribed already. When the appeal for the fund is complete permanent arrangements for administration of the scholarship fund will be made, but as several scholarships have been given outright the council has decided to make an interim award in 1950 of eight scholarships, each of £350. Further particulars may be had from the scholarships secretary of the fund, Dorset House, Stamford Street, London, S.E.1.

Registrars' Groups

At a meeting of registrars from six hospitals of the North East Metropolitan region, on Nov. 3, it was decided to form a registrars' group, and a provisional committee was elected. All registrars in this region are invited to attend a general meeting at Mile End Hospital, Bancroft Road, London, E.1, on Thursday, Dec. 8, at 8 P.M., when it is proposed to form a permanent committee.

In the Leeds region the committee of the newly formed group is made up of representatives from seven sub-regions. Further information may be had from the group's hon. secretary, Dr. P. R. R. Clarke, County Hospital, York.

Institute of Medical Laboratory Technology

At the annual meeting of this institute in Oxford on July 29, the following exemptions from institute examinations were approved.

Exemption from the final examination for associateship may be granted to those with a science degree (or associateship of the Royal Institute of Chemistry) in approved subjects, where the candidate has had not less than one year's experience in approved pathological laboratories. The above may qualify for fellowship by thesis after a further three years' experience.

Exemption from the intermediate examination may be granted to those having not less than 15 years' experience in approved pathological laboratories prior to July 29, 1949.

Copies of the institute's memorandum and articles of association may be obtained (price 1s. 2½d.) from the registered office, 76, Brewer Street, London, W.1.

London School of Hygiene and Tropical Medicine

Prof. Andrew Topping has been appointed whole-time dean of the school. He will take up his duties in the middle of February, 1950.

Dr. Topping, who is 58 years of age, graduated M.B. at the University of Aberdeen in 1914 and served with the R.A.M.C. in Gallipoli and Mesopotamia during the first world war. For some years he was senior medical o[illegible] and on his return to England he became r[illegible] Rochdale. After a period of service in t[illegible] service, he was deputy medical officer of [illegible]ity Council and lecturer in public health at Charing Cross Hospital medical school. After the second world war he became deputy chief of the relief services of UNRRA and later director of health of the European division. Dr. Topping is at present professor of social and preventive medicine in Manchester University. In 1944 he published, with Sir Archibald Gray, for the Ministry of Health, a *Survey of the Hospital Services in London and the South-East Counties.* He was elected F.R.C.P. in 1946.

The Royal Society of Medicine is to publish a full account of the symposium on psychosurgery by United States speakers, which was held by the psychiatry section of the society on Sept. 12 and 13, and was reported briefly in these columns (Sept. 24, p. 562). Application for copies, price 7s. 6d. each, should be made to the society's hon. editors, 1, Wimpole Street, London, W.1.

Births, Marriages, and Deaths

BIRTHS

BAIRD.—On Nov. 10, at Guildford, the wife of Dr. J. T. Ba a son.

DONALD.—On Nov. 16, at Inverness, the wife of Dr. W. A. Donald—a daughter.

MARRIAGES

HARRISON—LAMB.—On Nov. 18, in Auckland, New Ze William Rhodes Harrison, M.R.C.S., to Elisabeth Allison

DEATHS

CLUTTON.—On Nov. 19, at Crowland, Frank Husband Cl M.R.C.S., aged 78.

HARDING.—On Nov. 13, Robert Dennis Harding, B.A., D.M. M.R.C.P., D.T.M. & H.

McMURRAY.—On Nov. 16, in London, Thomas Porter McMur C.B.E., M.B., M.CH. R.U.I., F.R.C.S.E., aged 61.

THOMSON.—On Nov. 16, Andrew George Anderson Thom M.A., M.B. Aberd.

Prof. Crighton Bramwell is returning on Dec. 8 from three-week tour in Italy where he is lecturing on behalf the British Council.

Mr. C. Price Thomas and Dr. Robert Machray have left Portugal where they are to give a series of lectures on beh of the British Council.

Dr. Darma Setiawan, former minister of health in republican government of Indonesia and now personal advi to the republican premier of Indonesia, is visiting this coun at the invitation of the British Council to study public hea and hygiene in Britain and in particular the National Heal Service.

"PLEURAL SHOCK"

ANDREW MORLAND
M.D. Lond., F.R.C.P.
CIAN AND PHYSICIAN I/C TUBERCULOSIS DEPARTMENT,
UNIVERSITY COLLEGE HOSPITAL, LONDON

E first clinical description of "pleural shock" was : by Roger in 1864. While he was washing out a lic empyema cavity with an antiseptic, the patient, ild of 8 years, fell back unconscious, with clonic actions of arms and legs, but recovered after an . He called the condition pleural epilepsy because s leading symptoms, and attributed it to reflex n from stimulation of nerve-fibres in the pleura.

nilar cases were described later. In some there were r paralyses sometimes amounting to hemiplegia. mon symptoms were dilatation of one or both pupils, eration and weakness of the pulse, and visual rbances producing in some cases blindness lasting ral days. Most of the patients recovered, some ring temporary paralysis or weakness of the groups uscles which had been most affected by the spasmodic ractions. Some died, but no cause of death was d at necropsy.

ie reflex theory of pleural epilepsy received a rude k in 1912 when Brandes reported a case in which he injected bismuth paste through a sinus to outline pleural cavity. The patient died twenty hours later, at the necropsy bismuth paste was found in the bral vessels and elsewhere in the circulation.

INCIDENCE

s might be expected, the advent of artificial pneumo-ax increased the number of pleural accidents. lanini (1894) originally introduced air through a lle without manometric control; on reviewing his erience (Forlanini 1912) he stated that cerebral air olism belonged to the early historical period of umothorax treatment and could be avoided with ainty by modern technique; nevertheless he orted 12 examples (none of them fatal) of "pleural mpsia" in 134 patients. His most striking case-ord is that of a girl, aged 22, with a shallow icult left artificial pneumothorax, in whom "eclamp-" occurred on three successive refills; on the first asion she had a left brachial monoplegia with of consciousness; on the second she had similar ptoms with added spastic contraction of the left and on the third she had a left-sided hemiplegia hout loss of consciousness. Air embolism was clearly cause of this and other accidents described by lanini. Saugmann (1911), who used a manometer, ing had 2 fatalities from embolism in 269 patients, lanini attributed the relative frequency of his own idents to the more volatile nature of the Latin races pared with the Scandinavian.

he danger of air embolism caused Murphy (1898) to icise the puncture method of inducing an artificial umothorax and to prefer open incision of the parietal ura.

EXPERIMENTAL

Attempts to produce experimentally the phenomena "pleural shock" have given variable results. Capps d Lewis (1907) applied stimulants to the pleura with tle effect, except in animals in which pleurisy had been eviously induced. In these animals two types of reflex, rdio-inhibitory and vasomotor, were described; these ere exaggerated in the upright position, as is the rotid reflex.

Cordier (1910) injected iodine into the pleural cavity ithout manometric control and produced "pleural hock"; this effect did not follow when the vagi had een cut. Croizier (1927) repeated Cordier's experiments, but with manometric control, and found that "shock" came on only when iodine was injected directly into the lung, and that section of the vagi made no difference. On the other hand, Wever (1914) reproduced the typical picture of "pleural epilepsy" or "shock" by injecting air or gas into the carotid arteries of rabbits and monkeys. He also showed that, even with experimentally induced air embolism, changes in the brain cannot always be detected without special methods of staining.

CAUSATION

As the result of clinical experience and experimental findings embolism came to be looked on as much more common than reflex shock as a cause of accidents following paracentesis, and it has long been generally accepted that embolism is much the most likely cause of many different symptoms, the nature of which depends on the site of the embolism. These symptoms include visual disturbances either from air in the retinal vessels or in those of the occipital cortex, jacksonian contractions followed by weakness of the muscles most affected, and unconsciousness followed by headache on recovery. The skin in various parts of the body may show evidence of vascular disturbance in the form of patchy cyanotic mottling described as marbling.

Though embolism is the most satisfactory explanation of the great majority of pleural accidents, a small group remains in which the patient becomes suddenly unconscious and pulseless, respiratory failure and death following rapidly. Some workers looked on these cases as true examples of pleural shock, but evidence soon accumulated showing that not only cerebral but also coronary air embolism may follow paracentesis. Among the more interesting papers on this subject are those of Van Allen et al. (1929), who injected air into the pulmonary veins of dogs and found that, with the head lowered, coronary embolism invariably occurred, whereas, with the head raised, cerebral embolism was the rule; in the horizontal position either might occur.

Kent and Blades (1942) performed similar experiments and showed that death occurred from ventricular fibrillation, and that cardiac arrest preceded respiratory arrest. Cameron (1945) described a case in which the attempted induction of artificial pneumothorax produced sudden unconsciousness, cyanosis, tachycardia, and sweating; there was no evidence of cerebral air embolism, and the case would probably have been put down to "pleural shock" had the electrocardiogram not shown the presence of heart-block followed by evidence of coronary occlusion doubtless due to bubbles of air in the coronary vessels.

From the foregoing evidence it is clear that air embolism is the most likely explanation of the rare serious or fatal accident during pleural puncture. Sudden death, without sign or symptom of cerebral embolism, does not necessarily mean shock, since we now know that, with a patient in the horizontal position, air may occlude the coronary vessels. The passage of air through the chest wall is not essential for the production of air embolism, for it has been known to occur during the aspiration of fluid.

The only two cases of air embolism I have encountered were similar in type, both occurring during attempts to find a shallow pleural space. No satisfactory manometer reading was obtained, and no air was given, but the patients were breathing deeply, thus producing a low intrathoracic pressure. Both patients experienced "muzziness" in the head, associated with involuntary movements of one hand (the lower one). The symptoms passed off in a few minutes, leaving a headache which lasted a few hours.

Puncture of a healthy area of lung is unlikely to cause air embolism. I have even known a patient have weekly refills of 1000 ml. from an enthusiastic but inexperienced practitioner for a year with typical intrapulmonary pressure readings and no radiological evidence of air in the pleural cavity, and no ill effects resulted. This favourable experience was possibly due to the fact that the lung was perfectly healthy, the hæmoptysis for which the pneumothorax was attempted being due to a dry bronchiectasis on the other side. When lung tissue is indurated by chronic inflammation, the veins are held open and cannot contract when mechanically injured; in such circumstances a needle may well make a communication between airway and vein, and deep respiration may suck sufficient air into the vessel to cause embolism.

Needless to say, all cases of syncope during paracentesis are not due to air embolism; there are people, sometimes healthy young soldiers, who lose consciousness when they are given a hypodermic inoculation. In the near moribund, too, syncope, sometimes fatal, may follow various minor interventions, including pleural puncture. There are also rare cases, designated as status lymphaticus, in which some trivial operation causes death. None of these groups can properly be described as pleural shock.

Textbooks of medicine agree in advocating proper anæsthetisation of the pleura for the prevention of "pleural shock." Common humanity is also stated to dictate this procedure before a refill. Now I rarely use a local anæsthetic once an artificial pneumothorax has been properly established, since I find that the great majority of patients feel less pain when a fine sharp needle is inserted quickly than they do with the several prods necessary to anæsthetise skin, chest wall, and pleura.

The pleura is violently stimulated without local anæsthesia in the treatment of recurrent spontaneous pneumothorax by the method extensively used by Brock (1948), in which 0·5 ml. of a 10% solution of silver nitrate is injected into the pleural cavity, this procedure being followed immediately by aspiration of as much air as possible. So severe is the chemical stimulation of the pleura that it is usual to give a hypodermic injection of morphine shortly before the silver nitrate; even with this precaution some patients experience cramping pain, which may be so severe as to inhibit respiration for a moment. "Pleural shock" does not occur with this method, though the stimulation of the pleura must be many times greater than that produced by puncture.

CASE-RECORDS

Serious accidents in paracentesis are fortunately rare, and I have only been able to collect 5 cases during the past twenty-five years, an incidence of about 1 in 10,000 punctures of the pleura.

Case 1.—A man, aged 26, attended as an outpatient for aspiration of thick greenish fluid complicating his artificial pneumothorax and for a refill with air. Two needles were used, the upper connected with the pneumothorax apparatus so that pressure was kept constant. The fluid was aspirated with a 20 ml. syringe. The patient sat on a couch; at the end of the aspiration the needle was removed, and the patient leant back so that a few more syringefuls of fluid could be removed. He suddenly became faint and then immediately lost consciousness, with his pupils dilated, his pulse impalpable, and appeared to be dead. A syringe was filled with adrenaline with a view to injection into his heart, but the patient suddenly revived and was even the least shocked person present.

This case was looked on at the time as one of pleural shock. Coronary embolism might have given similar symptoms but was unlikely because (1) the lung was so far collapsed that it did not appear possible for the needle to have reached it, and (2) the patient being in a sitting position, any air entering the circulation would have been more likely to produce symptoms of cerebral embolism. It is noteworthy that the pleural walls were rigid from chronic inflammation, and the aspiration of a little fluid after removal of the air needle may have caused an unduly low negative pressure.

Case 2.—A woman, aged 25, had had a left pneumothorax induced in 1932 and abandoned in because of fluid. In May, 1938, the fluid was found creamy green pus containing tubercle bacilli but no organisms. Pleural irrigation with physiological saline was started, the first two irrigations being given in and the rest at the artificial pneumothorax clinic. pressures were kept low—e.g., −8, −9. The first six passed off without incident, but on the seventh, towards end of the operation, the patient fell back unconscious widely dilated pupils. A few more breaths were taken, neither pulse nor heart sounds were detected. Attempts start the heart, including cardiac massage, were unavailing.

Necropsy Findings.—At necropsy eighteen hours later heart showed moderate enlargement from dilatation of cavities and hypertrophy of the right ventricle. The right was normal, but the left lung was completely collapsed had enormously thickened pleura; 3 oz. of saline solution found in the pleural cavity. Measurements showed that aspirating needle was not long enough to have reached visceral pleura. The coronary and cerebral vessels showed evidence of embolism. The verdict was pleural shock.

Case 3.—A woman, aged 24, three months pregnant, acute lobar pneumonia in the left lower lobe. This responded to sulphapyridine, but an empyema had dev by the eighth day. For the purpose of diagnosis I asp the chest and withdrew 10 ml. of thin purulent fluid, contained numerous pus cells but no organisms. At th peutic aspiration five days later, with the pleura anæsthe the aspirating needle was inserted without difficulty the patient sitting up in bed. After only 10 ml. of fluid been aspirated, the patient fell back unconscious; in a m of seconds her breathing stopped, her pulse could not be and her pupils were widely dilated and did not react to li Her teeth were clenched; otherwise she appeared dead. recovered in two or three minutes.

An interesting feature of this case is that preci similar symptoms developed some six months l immediately after parturition (Dr. C. B. Thom personal communication).

Case 4.—A man, aged 38, had been admitted to Unive College Hospital with three weeks' history of pain in the lower chest (made worse by coughing and breathing), bre lessness on exertion, fever, and sweating on exertion. Th were physical and radiological signs of a right pleural effus The white-cell count was 13,600 per c.mm. (polymorphs 85 The pleural fluid was turbid, containing scanty cells (p morphs 47%, lymphocytes 29%) but no organisms. Cult proved sterile; 13 oz. of fluid was removed. Two days l 30 oz. of greenish-yellow turbid fluid was aspirated witho refill with air. The patient sat up in bed during the treatm Two days later 40 oz. of similar fluid was aspirated, and patient suddenly felt ill, appeared shocked during aspira and had a pulse typical of fibrillation. Some air was the allowed into the pleural cavity together with penicillin 500 units. Next day the pulse was still irregular, and elec cardiography confirmed that auricular fibrillation was pre This condition persisted for about twenty-four hours, which the pulse and the electrocardiogram became no Aspirations were continued without incident for three more, by which time the fluid had become thick and drainage was done.

Case 5.—A man, aged 52, had had a left pneumonectomy R. S. Pilcher) for oat-celled carcinoma; the tumour prob invaded the pericardium. Three days later 26 oz. of blo stained fluid was aspirated from the pleural cavity. Towa the end of this procedure the patient became shocked cyanosed and was found to have auricular fibrillation. Th rhythm became normal after two days and was unaffect by the further aspirations. The patient was discharged fa well but died from cerebral metastases eleven months aft operation.

DISCUSSION

The present series of 5 cases is obviously too small have any statistical significance apart from illustrat the rarity of such accidents. All the cases, however, sh following points: (1) the accidents took place during th aspiration of fluid, a procedure invariably preceded local anæsthesia; and (2) some degree of infection, or in case 5 irritation of the pleura, was present.

lysis of these cæsarean sections shows an important ion :

f incision	No. of cases	Maternal deaths	Infant deaths
d	8	2 (25%)	2 (25%)
segment	60	14 (23%)	31 (52%)
segment	76	7 (9·2%)	22 (29%)

e the introduction of sulphonamides in 1931 there been 61 lower-segment cæsarean sections after orceps in my hospital with 6 deaths (10%). In ten years, when blood-transfusion has been freely le, there have been 33 with 1 death. Penicillin n available for only three years so it is impossible r its effect, but I think we can say that nowadays uld expect a mortality of about 5%. No doubt herapy and antibiotics will reduce the mortality ryotomy after failed forceps, but I would not a reduction to much below 10%. for the deaths out equally shared between sepsis and trauma. otomy in these cases never has been, and never e, so safe as lower-segment cæsarean section. head is above the pelvic brim even though the s dead, cæsarean section is less damaging to the r, less liable to introduce infection, and more ing of hitherto hidden injuries to the uterus. etal mortality is appalling, but it is the antecedent f forceps, and not the operation, that kills the

incidence of failed forceps is dwindling every year h I think it will receive a fillip from the National a Service Act). Less and less experience in these will be acquired by any one operator ; so I wish to sise that nowadays the safest way is by cæsarean n, though I would not have it thought that I am ating cæsarean section for all failed forceps cases. ean section should be used in those patients with cted labour who would need it if there was no ion of infection. Among 307 cases of failed forceps d 57 cæsarean sections—about 1 in 5.

SUSPECT CASES

se here my own record of operations for I have careful private notes of all my cases. I have acted my last 500 cæsarean sections as they ide with the sulphonamide era ; but my record is d date, for there are six and a half years missing in bstetric life. Much better results would be achieved days. Of the 500 cæsarean sections 260 were gh the upper segment and 240 through the . Until about 1937 the lower-segment operation voided unless the woman was in labour, and many y cases were repeat operations on women who had dy had an upper-segment incision. 401 operations on clean cases, with 5 deaths ; 74 were on suspect , with 3 deaths ; and 25 were on failed forceps , with 3 deaths. The suspect cases are listed in e I. I have excluded all the women who were less twenty-four hours in labour with membranes ured, unless they had had outside operative interce such as vaginal plugging, or had other evidences fection.

here were 74 operations with 3 maternal deaths—). Exactly 50 of these operations were through the er segment with 2 deaths, both of which occurred he first 10. In 1921 the maternal mortality in this up was 9·4%. Infant deaths numbered 11 (15%)— gh figure, but a study of the table will show that ne of them were unavoidable.

Table I contains no reference to the number of times se patients had been examined vaginally before ration. The reason is that this number conveys thing. A single vaginal examination may convey ngerous organisms to the uterus. To set a certain mber of vaginal examinations as the limit after which u will not do cæsarean section seems to me folly.

TABLE II—SUMMARY OF 500 CASES OF CÆSAREAN SECTION

Type of case	Upper-segment section							Lower-segment section						
	Mother			Child				Mother			Child			
	Total	Lived	Died	Lived	Congenital malformation	Stillborn	Died	Total	Lived	Died	Lived	Congenital malformation	Stillborn	Died
Clean	232	229	4	196	6	11	19	169	168	1	158	5	2	4
Suspect	24	23	1	21	0	3	0	50	48	2	42	1	1	6
Failed forceps	4	4	0	2	0	2	0	21	18	3	14	1	5	1

Since we usually have no knowledge of the technique used in the examinations we should look on every woman who has been examined once as potentially septic, and the woman who has been examined ten times is still only potentially septic, though we should not on that account refuse her cæsarean section. An operator's cæsarean-section statistics will benefit from his refusal to operate on suspect cases, but his patients will suffer for it. A summary of the 500 cases is given in table II.

Penicillin and blood-transfusion will improve the results still further. I have concentrated on the results to the mother. My infant mortality is high. Many of the upper-segment operations were done for placenta prævia, and the mortality is made higher by the fact that there were 13 congenitally malformed babies in the 500. Fifteen years ago enteritis was a serious problem, whereas now it is hardly ever a significant cause of infant deaths.

TECHNIQUE IN INFECTED CASES

In all these infected and potentially infected cases we can discard the old operations of eventration of the uterus, and of fundal and upper-segment incisions. The evidence is overwhelming that the lower segment operation is safer. In many of our earlier cases a vertical lower-segment incision was used, and a drain was put down to the site of incision. Both of these have been discarded, and we now rely on transperitoneal section through a curved lower-segment transverse incision, subsequently sewn in two layers with continuous catgut, the bladder being replaced with a continuous catgut stitch, and the abdominal incision closed without drainage. Before the visceral peritoneum is incised, the general abdominal cavity is packed off with soft wet gauzes. To pack dry gauze into the peritoneum is like packing dry gauze into an eye.

I have never understood the efforts that have been made to devise a technique for extraperitoneal cæsarean section. It seems to me that they are based on lack of appreciation of the pathology of peritonitis. Peritoneum is miraculous in its ability to deal with infection. We have only to consider ruptured digestive ulcers, and more particularly war-wounds of the abdomen with soiling of the peritoneal sac, to have this fact brought home to us. Once the source of infection is cut off the peritonitis resolves rapidly, because the peritoneum can now prevent that infection from travelling through it to the susceptible subperitoneal tissue, which is a loose open network full of blood-vessels and lymphatics but devoid of intrinsic defence against infection. Patients die of subperitonitis, not of peritonitis. If infective liquor amnii is to be spilt, rather let it be spilt in the peritoneal sac than dispersed in the subperitoneal layers. For this reason the separation of the bladder should

Textbooks of medicine agree in advocating pr
anæsthetisation of the pleura for the prevention
"pleural shock." Common humanity is also state
dictate this procedure before a refill. Now I rarely u
local anæsthetic once an artificial pneumothorax
been properly established, since I find that the g
majority of patients feel less pain when a fine s
needle is inserted quickly than they do with the sev
prods necessary to anæsthetise skin, chest wall, and ple

The pleura is violently stimulated without
anæsthesia in the treatment of recurrent spontan
pneumothorax by the method extensively used
Brock (1948), in which 0·5 ml. of a 10% solution of s
nitrate is injected into the pleural cavity, this proce
being followed immediately by aspiration of as muc
as possible. So severe is the chemical stimulation
pleura that it is usual to give a hypodermic injecti
morphine shortly before the silver nitrate; even
this precaution some patients experience cramping
which may be so severe as to inhibit respiration
moment. "Pleural shock" does not occur with
method, though the stimulation of the pleura must
many times greater than that produced by puncture

CASE-RECORDS

Serious accidents in paracentesis are fortunately
and I have only been able to collect 5 cases during th
twenty-five years, an incidence of about 1 in
punctures of the pleura.

Case 1.—A man, aged 26, attended as an outpatie
aspiration of thick greenish fluid complicating his a
pneumothorax and for a refill with air. Two needle
used, the upper connected with the pneumothorax app
so that pressure was kept constant. The fluid was asp
with a 20 ml. syringe. The patient sat on a couch; at t
of the aspiration the needle was removed, and the p
leant back so that a few more syringefuls of fluid could
removed. He suddenly became faint and then immediatel
lost consciousness, with his pupils dilated, his pulse imp
pable, and appeared to be dead. A syringe was filled
adrenaline with a view to injection into his heart, b
patient suddenly revived and was even the least s
person present.

This case ~~was~~ looked on at the time as one of
shock. Coronary embolism might have given
symptoms but was unlikely because (1) the lung
far collapsed that it did not appear possible f
needle to have reached it, and the circulation
sitting position, any air entering ymptoms of c
have been more likely to produce sy pleural wal
embolism. It is noteworthy that th nd the aspira
rigid from chronic inflammation, air needle ma
a little fluid after removal of the ssure.

ttendant (case 3) were infected during the terminal of the illness, and at the necropsy, of case 5. was probably admitted to the hospital during the tion period of Q fever, and died of pneumonia after le illness lasting eleven days. The pathologists e post-mortem attendant may have been infected dling organs from case 5, or more probably by g droplets resulting from splashing or cutting such as the lung. It is of interest in this connexion post-mortem attendants are listed amongst the ses of Q fever described by Beck et al. (1949). ossible danger of infection at post-mortem exami- of patients dying of atypical or virus pneumonia be borne in mind.

estigation of case 5's household, in a coastal town th-east England, showed that his wife (case 6) lso infected; and efforts to find their source of on have revealed that cattle, farmers, and dairy- s in that district have serological evidence of on and that *R. burneti* is present in raw milk from of the farms in the area. The cows show no signs ess. The epidemiological relationship of cases 7 to the others (1–5) at the Royal Cancer Hospital is ot clear. Probably they were infected from some source, but this is still under investigation.

ISOLATION OF A RICKETTSIA

en possible, specimens of serum from the patients acute and convalescent phases were examined by mplement-fixation test, using the Henzerling strain *burneti*; detailed results are given in Harman's Isolation of the rickettsia was also attempted, whole blood or blood-clot from cases 1, 2, and 7. mens were taken on the eighth, ninth, and third the disease, respectively. Cases 1 and 7 were then ebrile, but case 2 had been afebrile for three days. lation into guineapigs of blood from cases 2 and not lead to the development of fever or antibodies, *burneti* was isolated from the blood of case 1. Isolation is described below.

od from case 1 which had been stored in an electric ator at −60°C for five days was thawed and bacterio- l cultures were made. The blood was sterile. The next 1 ml. of blood was inoculated intraperitoneally into eapigs (1 and 2) weighing 250–300 g. Temperatures taken morning and evening and remained within the al limits for our stock until the morning of the twenty- d day, when guineapig 1 had a temperature of 104°F. on this had risen to 106°F and the animal was killed ether. The spleen was deep red in colour, very soft and e, and twice natural size, although the animal had been st before inspection. No other abnormality was found. n, whole blood, and spleen were stored at −60°C after lation of bacteriological media. Guineapig 2 remained le, showed no rise in antibodies, and, when subsequently nged with the homologous strain, had an afebrile illness production of specific antibodies. The cultures of guinea- were sterile after forty-eight hours' incubation, and ml. of the blood was inoculated intraperitoneally into apigs 3 and 4, and 0·75 ml. of 10% spleen suspension ritoneally into guineapigs 5 and 6. Guineapigs 3 4 had a three-day febrile illness from the seventh to day and recovered. They were later shown to have oped complement-fixing antibodies for a known strain *burneti* (Henzerling). Guineapig 5 developed fever with mperature of 104·8°F on the sixth day and was killed. eapig 6 remained afebrile but produced complement- g antibodies. Similar results were obtained when spleen blood of guineapig 5 were inoculated into further eapigs.

he blood of case 1 was not inoculated into eggs, but the en suspension of guineapig 1 was inoculated into the k-sac of 5 eight-day embryos, the youngest available at t time, which were then incubated at 36°C. On the fifth 2 of the embryos were dead and 3 sluggish. The yolk-sacs e removed and smears made. The yolk-sacs of 3 living *b*, and *c*) and 1 dead (*d*) embryo were free of bacteria, but the yolk-sac of the other dead embryo was contaminated with bacteria and was discarded. No definite rickettsiæ were seen in yolk-sac smears stained with Macchiavello or Giemsa stains. A pooled 20% suspension of yolk-sac of eggs *a*, *b*, and *d* was inoculated into yolk-sacs of 3 six-day embryos (eggs *f*, *g*, and *h*). The eggs were dead on the fourth day and yolk-sacs were removed. Organisms similar to *R. burneti* were found in smears from all yolk-sacs. 0·2 ml. of yolk-sac egg *f* was inoculated intraperitoneally into two 500 g. guineapigs (23 and 24), and though there was no febrile response both developed complement-fixing antibodies. In confirmation of this two 300 g. guineapigs (26 and 27) were each inoculated with 0·4 ml. of yolk-sac egg *f*, and 1·0 ml. of yolk-sac egg *g* (both bacteriologically sterile). Six days after inoculation both guineapigs had fever, that of guineapig 26 lasting five days and that of guineapig 27 two days. Both had a rising titre of complement-fixing antibodies, while an uninoculated guineapig in the same cage was not ill and did not develop antibodies.

The relation of this strain, and others isolated from raw milk, to the American (Nine Mile) and the Italian (Henzerling) strains of *R. burneti* is being investigated.

SUMMARY

A strain of *Rickettsia burneti*, the causative agent of Q fever, has been isolated from 1 of a group of 7 serologically proven cases of Q fever associated with an outbreak at the Royal Cancer Hospital.

Epidemiological investigations have established the existence of an endemic focus of the disease in south-east England, and further investigations are being carried out to estimate the prevalence of the disease in man and animals in other parts of the country.

Attention is drawn to the need for care in removing serum from the blood-clot of cases of atypical pneumonia and in handling the organs of fatal cases of pneumonia.

Thanks are due to Miss B. Lewis, resident medical officer at the Royal Cancer Hospital, for much help in collecting specimens, and to Prof. R. A. Willis and Dr. J. W. Whittick and Dr. A. C. Christie, of the pathological department, for much information about cases. Dr. C. E. Etheridge, Dr. T. A. R. Callender, Dr. Thomas Glynn, and Mr. F. W. Whitehouse, sanitary inspector, gave much willing and appreciated coöperation in the epidemiological investigations of cases 5 and 6. We are particularly grateful to Dr. Herald R. Cox, of the Lederle Laboratories, U.S.A., for providing a supply of *R. burneti* antigen for the complement-fixation tests. We should also like to acknowledge with thanks the technical assistance of Mr. J. R. McDonald.

"... It will be remembered that some portion of Battersea Park was devoted last year to rather problematic statuary of different kinds. I would suggest in order to provide a fitting emblem of that universal amity which the Government have been so successful in establishing, the right hon. Gentleman commission someone, preferably Mr. Henry Moore, to provide a statuary group of the Minister of Health embracing Lord Horder. That would have two advantages. It would attract all the innumerable friends and admirers of the Minister of Health, and it would attract all the innumerable friends and admirers of Lord Horder. If, moreover, the sculptor could recall to some extent the famous statue of Laocoon, and subtly suggest the idea of the Minister of Health struggling with a serpent—or conversely Lord Horder struggling with a serpent—the cup of public enjoyment would be filled to overflowing."—Mr. WILSON HARRIS in the debate on the second reading of the Festival of Britain Bill, *Hansard*, Nov. 23, column 423.

be not more than is necessary. Deliberately to open wide areas of subperitoneal tissue because the liquor amnii may contain infection is to put infection under a membrane which would much prefer to have that infection on its surface.

SUMMARY

Where it is indicated cæsarean section should not be refused because of the presence or suspected presence of infection. Other methods of delivery are more dangerous.

The mortality of cæsarean section in infected cases with penicillin, sulphonamides, and blood-transfusion is less than 5%.

The mortality of embryotomy after failed forceps has been 20%; though with penicillin, sulphonamides, and blood-transfusion it may be less.

Q FEVER IN GREAT BRITAIN

ISOLATION OF RICKETTSIA BURNETI FROM AN INDIGENOUS CASE

F. O. MacCallum M.D. Toronto
B. P. Marmion M.D. Lond.
OF THE VIRUS REFERENCE LABORATORY, CENTRAL PUBLIC HEALTH LABORATORY, COLINDALE, LONDON

M. G. P. Stoker
M.D. Camb.
LECTURER IN PATHOLOGY, UNIVERSITY OF CAMBRIDGE

Q FEVER was first described by Derrick (1937) in Queensland, Australia; and the ætiological agent, now known as *Rickettsia burneti*, was isolated by him and identified as a rickettsia by Burnet and Freeman (1937). At about the same time, a similar organism was isolated by Davis and Cox (1938) from wood ticks, *Dermacentor andersoni*, caught at Nine Mile Creek, Missoula, Montana, U.S.A.; it was named *R. diaporica* because it passed certain bacteria-retaining filters. The two rickettsiæ were later shown to be closely related if not identical. More recently, American workers have suggested that the properties of these organisms are sufficiently different from those of other rickettsiæ to warrant a separate generic name, and they are described as *Coxiella burneti*.

In recent years Q fever has been identified in Greece, Italy, Algiers, Morocco, Turkey, Iraq, Switzerland, France, Germany, and Panama, as well as in the U.S.A. and Australia. Investigations of the epidemiology of the disease in these countries show that the animal reservoirs of the disease and its mode of spread vary considerably according to local geographical and biological conditions. Nevertheless, a brief review of the findings in Australian, Italian, and Californian outbreaks will indicate some of the possibilities to be considered in investigating a case or an outbreak of Q fever.

PREVIOUS OUTBREAKS

In the seven years following the discovery of Q fever in Australia, Derrick and his colleagues found 176 cases of the disease (Derrick 1944). All the patients, with one exception, lived in the coastal area of south-east Queensland—129 of them in Brisbane and 47 in the surrounding countryside. Most of the Brisbane patients worked at the meat-packing plant where the original cases described by Derrick had occurred, and it was hoped that an analysis of their jobs in the meat works would indicate precisely the source of their infection. On the contrary, it was found that workers anywhere in the plant, including secretarial and mechanical staff, were liable to infection. This fact, together with the low infectivity of cattle tissues, was against infection by handling of, or splashing from, cattle organs. The occupational association with cattle was striking however; for in addition to the cases at the meat works, 37 of the 47 country patients lived or worked on dairy farms or in contact with stock. A serological survey of area showed that some were infected; and a natural reservoirs of the disease in bush their parasites—resulted in the isolation of R. from the bandicoot, *Isoodon torosus*, and its —the tick, *Hæmaphysalis humerosa*.

This suggested that the infection might be in nature by a tick-bandicoot-tick cycle, but it to explain the human infections, because *H.* reluctant to feed on man and is only an parasite of cattle. Moreover, a history of tick- very rarely obtained from cases of Q fever. (1944) suggested, however, that the infection of and abattoir workers might be due to the inhalati dust containing infectious, dried, tick excreta fro hides of the cattle. Though the ticks (*Hæmaph bispinosa* and *Boophilus annulatus microplus*) comm found on the cattle could be artificially infected, were not shown to be infected in nature.

The theory of infection of man by inhalation of dust—whether contaminated by tick excreta or secretions or in some other way—has received able epidemiological support from outbreaks of Q fever amongst Allied troops in where a relationship was found between dusty hay in bedding or dust in barns, &c., and outb of the disease (Robbins et al. 1946, Commission on A Respiratory Diseases 1946). This theory is reinforce the epidemiological association of Q fever with pack straw in a crate of American machinery received Swiss firm (Wegmann 1948), and the isolation of *R. bu* from the dust of sheep-pens in a north Califo outbreak (DeLay et al. 1949).

In Los Angeles county, south California, whe fever is endemic, intensive studies are being carried Beck et al. (1949) have analysed the epidemiology of cases of Q fever and concluded that infection was ciated almost entirely with either direct occupa exposure to cattle or residence close to dairy farm with drinking raw milk infected with *R. burneti.* north California, on the other hand, infection appea be due to occupational exposure to sheep and rather than to contact with cattle or consumptio infected raw milk.

Epidemiological data from these and various labor outbreaks indicate that the incubation period is 19 days, with a range of 14–26 days, and that case-to spread of the disease is rare. The hypothesis migh formed, then, that Q fever is primarily an infectio arthropods and animals which occasionally spread man owing to the inhalation of infected dust or consumption of infected milk and milk products. An reservoirs of the disease have varied in different coun and possibly in Great Britain the epidemiology will in some particular from the outbreaks already desc

Q fever has only recently been recognised in Britain. Stoker (1949) reported 2 cases diagnosed serological examination (complement fixation) in R personnel. Since late 1948, serological investigation 237 patients variously diagnosed as atypical or vi pneumonia, "influenza," or pyrexia of unknown orig has revealed 4 cases—the 2 mentioned above and the oth others, one in a radio mechanic in Bristol and the in an agricultural engineer at Banbury, Oxfordshire. should be mentioned that the series is rather selecti being composed mostly of patients living in or n London.

EPIDEMIOLOGY OF PRESENT OUTBREAK

The cases described in an accompanying paper b Harman have been the subject of an extensive epidem logical investigation, details of which will be publi later. At present it seems that the nurse (case 2), t two pathologists (cases 1 and 4) and the post-mortem ttendant (case 3) were infected during the terminal of the illness, and at the necropsy, of case 5. was probably admitted to the hospital during the tion period of Q fever, and died of pneumonia after le illness lasting eleven days. The pathologists e post-mortem attendant may have been infected dling organs from case 5, or more probably by g droplets resulting from splashing or cutting such as the lung. It is of interest in this connexion post-mortem attendants are listed amongst the ases of Q fever described by Beck et al. (1949). ossible danger of infection at post-mortem exami- of patients dying of atypical or virus pneumonia l be borne in mind.

estigation of case 5's household, in a coastal town th-east England, showed that his wife (case 6) lso infected; and efforts to find their source of ion have revealed that cattle, farmers, and dairy- rs in that district have serological evidence of ion and that *R. burneti* is present in raw milk from of the farms in the area. The cows show no signs less. The epidemiological relationship of cases 7 to the others (1–5) at the Royal Cancer Hospital is ot clear. Probably they were infected from some source, but this is still under investigation.

ISOLATION OF A RICKETTSIA

en possible, specimens of serum from the patients acute and convalescent phases were examined by mplement-fixation test, using the Henzerling strain *burneti*; detailed results are given in Harman's . Isolation of the rickettsia was also attempted, whole blood or blood-clot from cases 1, 2, and 7. mens were taken on the eighth, ninth, and third f the disease, respectively. Cases 1 and 7 were then ebrile, but case 2 had been afebrile for three days. lation into guineapigs of blood from cases 2 and not lead to the development of fever or antibodies, *R. burneti* was isolated from the blood of case 1. isolation is described below.

od from case 1 which had been stored in an electric erator at −60°C for five days was thawed and bacterio- l cultures were made. The blood was sterile. The next 1 ml. of blood was inoculated intraperitoneally into ineapigs (1 and 2) weighing 250–300 g. Temperatures taken morning and evening and remained within the al limits for our stock until the morning of the twenty- d day, when guineapig 1 had a temperature of 104°F. oon this had risen to 106°F and the animal was killed ether. The spleen was deep red in colour, very soft and le, and twice natural size, although the animal had been ut before inspection. No other abnormality was found. n, whole blood, and spleen were stored at −60°C after lation of bacteriological media. Guineapig 2 remained ile, showed no rise in antibodies, and, when subsequently nged with the homologous strain, had an afebrile illness roduction of specific antibodies. The cultures of guinea- 1 were sterile after forty-eight hours' incubation, and ml. of the blood was inoculated intraperitoneally into eapigs 3 and 4, and 0·75 ml. of 10% spleen suspension ritoneally into guineapigs 5 and 6. Guineapigs 3 4 had a three-day febrile illness from the seventh to h day and recovered. They were later shown to have loped complement-fixing antibodies for a known strain *R. burneti* (Henzerling). Guineapig 5 developed fever with mperature of 104·8°F on the sixth day and was killed. neapig 6 remained afebrile but produced complement- g antibodies. Similar results were obtained when spleen l blood of guineapig 5 were inoculated into further neapigs.

he blood of case 1 was not inoculated into eggs, but the en suspension of guineapig 1 was inoculated into the k-sac of 5 eight-day embryos, the youngest available at at time, which were then incubated at 36°C. On the fifth y 2 of the embryos were dead and 3 sluggish. The yolk-sacs re removed and smears made. The yolk-sacs of 3 living , *b*, and *c*) and 1 dead (*d*) embryo were free of bacteria, but the yolk-sac of the other dead embryo was contaminated with bacteria and was discarded. No definite rickettsiæ were seen in yolk-sac smears stained with Macchiavello or Giemsa stains. A pooled 20% suspension of yolk-sac of eggs *a*, *b*, and *d* was inoculated into yolk-sacs of 3 six-day embryos (eggs *f*, *g*, and *h*). The eggs were dead on the fourth day and yolk-sacs were removed. Organisms similar to *R. burneti* were found in smears from all yolk-sacs. 0·2 ml. of yolk-sac egg *f* was inoculated intraperitoneally into two 500 g. guineapigs (23 and 24), and though there was no febrile response both developed complement-fixing antibodies. In confirmation of this two 300 g. guineapigs (26 and 27) were each inoculated with 0·4 ml. of yolk-sac egg *f*, and 1·0 ml. of yolk-sac egg *g* (both bacteriologically sterile). Six days after inoculation both guineapigs had fever, that of guineapig 26 lasting five days and that of guineapig 27 two days. Both had a rising titre of complement-fixing antibodies, while an uninoculated guineapig in the same cage was not ill and did not develop antibodies.

The relation of this strain, and others isolated from raw milk, to the American (Nine Mile) and the Italian (Henzerling) strains of *R. burneti* is being investigated.

Q FEVER IN GREAT BRITAIN

CLINICAL ACCOUNT OF EIGHT CASES

J. B. HARMAN
M.D. Camb., F.R.C.P.
PHYSICIAN, ST. THOMAS'S HOSPITAL, LONDON; ASSISTANT PHYSICIAN, ROYAL CANCER HOSPITAL

LAST July, two members of the staff of the Royal Cancer Hospital fell ill with symptoms and signs which strongly suggested Q fever. The diagnosis was confirmed by serological tests and by isolating *Rickettsia burneti* from one of them, and a search revealed six further cases. The epidemiology and isolation of the organism are discussed by MacCallum et al. in an accompanying paper.

This is the first time that Q fever has been detected in the active state in this country; but the disease may prove to be not uncommon here.

Nearly a thousand proved cases have been published (Huebner et al. 1949, Beck et al. 1949); and it is now known that hundreds of cases arose in Italy and the Balkans during the late war, though these were called "Balkan Grippe" by the Germans (Imhäuser 1943) and atypical pneumonia by the British (Turner 1945). This experience is large enough for a clear clinical picture to be drawn, especially as all cases are remarkably similar except in severity.

CLINICAL FEATURES

The fever starts suddenly, and it is often possible to time its beginning to the hour. At first the symptoms may be mild, so that the patient is not driven to bed for several days. The temperature is high, 104°F being quite common. It sometimes falls to normal more than once a day; and these swings are accompanied by rigors and drenching sweats. In view of the high temperature the pulse-rate is remarkably slow; it often remains at 70 per minute. When the attack is fully developed prostration is even more severe than might be expected from the height of the fever. Delirium is quite common, and typhoid state and coma have been reported. Muscle and back aches are early symptoms, but these are soon overshadowed by headache, which is continuous behind the eyes or at the back of the head. Patients are wary of changing position and try to stifle coughing lest this aggravate the headache; they may prefer to be in a shaded room, but meningeal rigidity is absent.

Within a week a tickling unproductive cough begins, but it rarely develops further, though sputum and even small hæmoptyses have been described. In the original Australian cases (Derrick 1937) no chest signs were noticed, but they are now known to be constant though perhaps not prominent, in any moderately severe case. These signs consist in a small patch of persistent tissue-paper crepitations and high-pitched bronchial breath-sounds, usually at the base. In a recent American series (Beck et al. 1949) more obvious signs have been found, especially in older people, indicative of frank lobar consolidation, and pleuritic friction and fluid. The radiological signs are clearer, and since they may persist for weeks they have been used as a method of surveying infected persons during an outbreak. These suggest lobular partial consolidations, usually at the base though any lobe may be affected; collapse and pleural effusion may be seen.

Certain striking absences in the symptomatology should be noted. Apart from the anorexia and nausea of fever, gastro-intestinal symptoms are rare. There is no skin rash such as characterises many other rickettsial infections. There is no coryza as is common in acute respiratory disease due to viruses. Complications are hardly ever seen.

The course is variable; usually the disease persists for a week; but mild and subclinical infections are relatively numerous. Occasionally fever remains high for a few weeks, or even a month; termination is by
Relapse of fever has been noticed (Commission on Respiratory Diseases 1946); and 4 cases have recorded in which a low continued fever was
to a frank attack of Q fever—in 1 case as long
years before (Beck et al. 1949). Postfebrile
and aching and weakness in the legs may be
weeks or months, especially by older people.
death-rate in clinically ill cases appears to be in
neighbourhood of 1 in 500; fatalities are mostly con
to people over fifty years of age suffering from
other, chronic, disease.

Although the clinical manifestations are very const
they do not easily serve to distinguish Q fever
short-term fevers. In fact Q fever has usually dr
attention to itself by its epidemic constitution. It
first observed as a fever peculiar to slaughterhou
and was next seen among other kinds of cattle
it became an "occupational" fever. The M
cases did not show special contact with cattle,
physician could fail to recognise a disease
the explosive outbreaks that were seen there.
outstanding features were: the explosive
high attack-rate, restriction to military units
certain quarters, and absence of an associated
in upper-respiratory infections. Subsequent expe
has confirmed the remarkable absence of any case-to-c
spread.

TREATMENT

The sulphonamides, penicillin, and probably strep
mycin, are useless. Chloramphenicol is very effect
against other rickettsial diseases such as typhus, scru
typhus, and Rocky Mountain spotted fever; but th
are no published records of its use in Q fever. 'Au
mycin' has a very powerful suppressive action on exp
mental infections of eggs and guineapigs with
rickettsiæ of typhus, scrub-typhus, Rocky Mount
spotted fever, and Q fever (Wong and Cox 1948). Ag
typhus and spotted fever in man it has had only a lim
trial; but 19 cases of Q fever have been treated (Len
et al. 1948). The results were promising, though 1 not
failure was seen and in others cure was delayed.

CASE-RECORDS

Case 1.—A pathologist, aged 29, who made the post-mor
examination of case 5, had malaise from July 11 to 13.
the 14th he had pain in the buttocks and frontal head
relieved by aspirin; the temperature in the evening
103°F. On the 16th he was admitted to hospital with fever and lethargy, having vomited after breakfast.

Frontal headache was very severe and he insisted on his room being darkened. There was no neck rigidity. Intermittent fever, rising to 105°F, persisted for seven days, but the pulse-rate remained between 80 and 110 per min. (see fig. 1). He had several rigors daily and drenching sweats. By day he was irritable and by night slightly delirious. The total white blood-cell count remained around 7000 per c.mm.

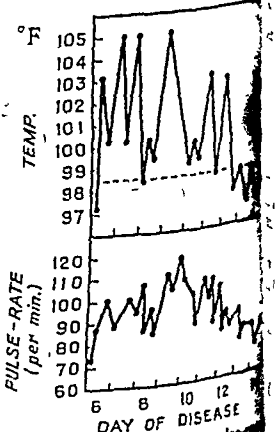

Fig. 1—Temperature and pul
in case 1.

On the 17th a tickling cough started, with "rawness" of the trachea. On the 20th there was a patch of tubular breath-sounds at the base of the right lung, and
radiography showed consolidation of this area. He develop
a furuncle in the ear and a small ulcer inside the cheek.

On the 21st, at 8 P.M., he was given chloramphen
3·5 g., followed by 0·25 g. every three hours for the

y-six hours (total 6·25 g.). On the morning of the 22nd emperature rose to 102°F, but thereafter it was normal; ever had lasted twelve days. He continued to be miserable photophobic for a further twenty-four hours, during which he had dryness of the mouth and sudden attacks of go, possibly due to the drug. He was discharged on 24 and returned to work ten days later, feeling well. X-ray changes cleared between Sept. 1 and Oct. 5.

e titre of complement-fixing antibodies to *R. burneti* less than 1/10 on July 21 and rose to 1/640 by Aug. 9. *rneti* was isolated from the blood.

se 2.—On the morning of July 10, a nurse, aged 30, had nursed case 5 and laid out the body, suddenly n to have severe frontal and occipital headache. This somewhat relieved by aspirin, but she had to take so that she vomited. She continued to work for four days, n the fourth day had aches and pains all over the body. day (July 14) she went to bed with a temperature 4°F, and pulse-rate 120 per min.; she was perspiring sely and had a rigor lasting three minutes. There was ophobia but no neck rigidity; she had to remain still for of making the headache worse.

the 15th a small patch of crepitations and faint tubular hing was detected posteriorly at the right base, but tero-anterior radiogram showed nothing abnormal. The white-cell count was 9200 per c.mm. A lumbar puncture done because it was suspected that the patient and olleagues were fearful of meningitis. The cerebrospinal was chemically and cytologically normal; the pressure not measured.

e fever fell by lysis in the next three days, having lasted days. The patient was discharged on the 19th and was at work a week later.

e titre of complement-fixing antibodies for *R. burneti* /10 on July 20 and rose to 1/320 by Aug. 9.

th case 1 and case 2 had the typical symptoms of ver and were clinically diagnosed as such. Case 1 moderately severe.

se 3.—A necropsy-room attendant, aged 51, who had ed at the post-mortem examination of case 5, became ally ill about July 9. He felt weak and had very severe che: "I tried everything but it was no good." He came very hot about twice a day and could not sleep for sness. He had always been "chesty," and his cough ne worse after about five days. Sulphonamides and illin had no effect.

the 16th he was admitted to St. Helier Hospital under are of Dr. C. P. Petch. He was described as an obese oric man with chronic bronchitis and emphysema; were râles at both bases. For six days he ran a nued fever of 102–103°F; the pulse-rate varied from 108 per min. (fig. 2). He was drowsy most of the and complained of no particular symptoms apart being "downright ill." Total white-cell counts of 6900 300 per c.mm. were recorded during the fever.

sputum was purulent and intermittently streaked with . X-ray examination of his chest, on admission, showed y consolidation in the right upper lobe. Another film ly 30 showed a small effusion at the lower end of the right ue fissure and bronchopneumonia in both lungs. The changes cleared between Aug. 16 and Oct. 13.

July 22 he felt much better; his temperature fell to and was normal the next day. He got up, but between 29 and Aug. 1 he had three sharp rises of temperature leuritic pain in the front of the right side of the chest. ion was thought to be heard here, and, more certainly, e left base at the end of the first week in August. Râles nued in his chest throughout his stay in hospital and were present in October.

nvalescence was slow. He did not feel quite well when turned to work at the beginning of October. In the le of October he was still complaining that his legs , and he felt that it was too much trouble to walk about. as not sleeping as well as usual. He has not been out of and since the first world war.

e titre of complement-fixing antibodies for *R. burneti* /640 on Sept. 1.

hen first seen this patient was thought to have a lung tion secondary to chronic bronchitis. The diagnosis soon changed to atypical pneumonia, and aureo- n would have been given on July 22 had not his temperature started to fall. Looking back on the case, the usual characters of moderately severe Q fever can be distinguished, though veiled by chronic bronchitis. Relapse is uncommon in Q fever though it may be commoner in older people than our first experience in young soldiers led us to believe. It is not possible to say whether the recurrence of fever at the end of July was due to Q fever or to bronchitis.

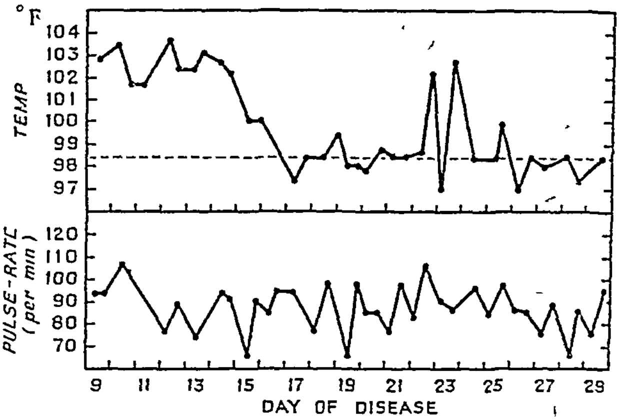

Fig. 2—Temperature and pulse-rate in case 3.

Case 4.—A pathologist, aged 50, who watched the post-mortem examination of case 5, gives this retrospective account: "On about July 1 I began to have pain in the lower abdomen, mainly on the right side. It was continuous and aching and spread into the groin and right testicle. I had borborygmi; my bowels were slightly irregular; and I do not think I had any fever. These symptoms continued with a gradual crescendo until I went to bed on July 13 with a temperature of 102°F. By that time the pain in the abdomen and testicle was quite prominent and distressing. I had no cough and no more headache than would be expected with the fever. My urine was normal and the white-cell count 6500 per c.mm. On July 14 Dr. F. Avery Jones saw me. He found that my chest was normal and suggested that I had some vague intestinal infection. He put me on phthalysulphathiazole. On the 16th I was well and on the 17th out of bed; and on the 18th I was back at work."

Thus fever had lasted 1–2 days. The patient is an Australian, but has lived in England since 1945 except for a holiday in Norway in 1948.

The titre of complement-fixing antibodies for *R. burneti* was 1/80 to 1/60 on Sept. 1.

This illness is quite unlike Q fever, in which all observers agree that abdominal symptoms are notably absent. It started only a week after the patient attended the post-mortem examination of case 5—which is too short an incubation period. Nevertheless he must have been infected in England unless his antibodies remained high for over four years after an unrecognised infection in Australia. The fever which finally sent him to bed on July 13 occurred at a time consistent with infection at the post-mortem examination of case 5. Probably he was suffering from some intestinal infection, complicated at the end by a very mild attack of Q fever.

Case 5.—A man, aged 78, was admitted to the Royal Cancer Hospital in May, under the care of Mr. R. W. Raven. He complained of dysphagia, which turned out to be due to bulbar palsy; when he swallowed barium it flowed into the bronchi.

Nearly three weeks after admission—on June 14—his temperature suddenly rose to 102°F (fig. 3). Fever continued and was unaffected by sulphonamides or penicillin. He had signs of pneumonia and developed auricular fibrillation. He regurgitated food, became incontinent, and rapidly sank into coma, dying eleven days after the onset.

Post-mortem examination on June 25 confirmed the cerebral degeneration. The spleen was slightly enlarged, soft, and mushy; there was pronounced reactive hyperæmia.

In the lungs the right lower lobe was completely consolidated with lobar pneumonia; there was red hepatisation in the upper part and grey in the lower. The left lung was congested but otherwise normal. All bronchi were congested, those on the right being filled with mucopus. The trachea was slightly congested and contained much mucopus. Histologically the pneumonia showed unusual features. It was diffuse and yet unlike either classical lobar pneumonia or confluent bronchopneumonia. In the early stages the reaction was notably œdematous. In the fully developed lesion there were many mononuclear cells in the exudate, and the interstitial connective-tissue was widened by inflammatory changes. There was a relative scarcity of neutrophil polymorphs and fibrin. This picture resembles that of a fatal case of Q fever described by Lillie et al. (1941). The absence of food particles and of suppuration excludes the possibility of inhalation pneumonia, and the reaction is unlike that of lipoid pneumonia.

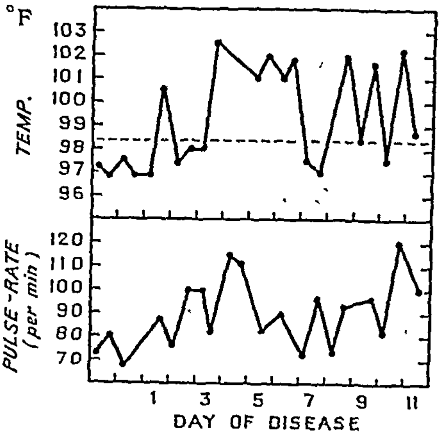

Fig. 3.—Temperature and pulse-rate in case 5.

Preliminary attempts to find rickettsiæ by a modified Giemsa method show minute pink coccoid bodies which may be of significance. A fuller description will appear elsewhere.

Bronchopneumonia was expected, and nothing unusual was suspected when it developed. Q fever did not break out in the hospital until over two weeks after this patient's death. Retrospectively, however, it is presumed that he had Q fever, on the following grounds: (1) the histological changes in the lung; (2) the serological evidence of infection in his wife (case 6), who had never visited the Royal Cancer Hospital but, like the patient himself, is known to have been in contact with an endemic focus at their home on the south-east coast; and (3) the link afforded by this patient between this focus and the hospital cases. Detailed epidemiological evidence will be presented in a further publication.

Case 6.—In this patient, the wife of case 5, there is no reliable history of recent fever. A complement-fixation test for *R. burneti* antibodies showed full fixation at 1/320 and 50% fixation at 1/640.

Case 7.—The patient, a physicist, aged 40, suddenly felt weak and feverish at 11 A.M. on Sept. 7. He carried on but spent a restless night. The next day he tried to work but was admitted to hospital. He felt hot and "swimmy," with slight aching in bones and joints. There was no constant headache, but "the top of my head lifts off if I cough." He ran a fever of 100–103°F for three days, after which the temperature fell by lysis. The fever had lasted altogether five days. He had rigors and drenching sweats though his fever at no time was very high. The pulse-rate was constantly 70–80 per min.

Slightly tubular breathing and faint tissue-paper crepitations were heard at the left lung base on Sept. 8. X-ray examination showed no abnormality. On Sept. 10 the total white-cell count was 10,400 per c.mm.

He returned to work on Oct. 3 but did not feel fit until two weeks later; meanwhile he felt "woolly" in the head, could not concentrate, got palpitations and went hot with exercise, and his legs felt too dead to move.

The titre of complement-fixing antibodies for *R. burneti* was less than 1/5 on Sept. 9, but had risen to 1/40 to 1/80 by Oct. 7.

Case 8.—This patient, aged 29, is the wife of case 7. On Sept. 9 she suddenly had rigors and fever. She could not sleep that night and had big sweats. There was pain at the bottom of the spine and "a colossal throbbing" in the back of the head. The worst day was Sept. 11. The temperature was 104°F on the 12th, when she was still having sweats. On the 13th some fine crepitations were heard at both bases. She continued like this until the 17th when she started to get up; she was fully up by the 21st but only "crawling ...ay" and feeling ill. The fever had lasted probably nine days. By Oct. 18 there were no signs in the the radiographic appearance was normal. The complained, however, of headache, a rattling depression.

The titre of complement-fixing *antibodies* for *R.* was less than 1/10 on Sept. 12, and rose to 1/80 on the

Both cases 7 and 8 were moderately severe and in convalescence. A *clinical diagnosis of Q* was though no connexion could be traced with the other ca They would have excited no particular comment if had not been on the look-out for more cases.

DISCUSSION

Now that Q fever has appeared in England, it well be asked what importance it has for the practi physician. This *question cannot be answered* until frequency here has been judged by serological surv of likely cases. The most promising field is among the sho term fevers passing under vague titles such as " or among longer fevers such as "atypical pn *monia." No explosive outbreaks or fevers* peculiar handlers of cattle or sheep, or of their products, have noticed in this country; but serological tests may show that infection of this group has in fact taken Relapsing and chronic cases would be particu *important to the physician because, if* undiagnos they would *cause considerable difficulty* and anxie Yet the diagnosis of Q fever can easily be confirmed refuted, because the complement-fixation test becom positive 7–12 days after the onset of fever.

SUMMARY

The clinical features of Q fever are described. Eight cases arising in England are reported.

I wish to express my thanks to Dr. E. G. Lewis for her with the cases, and to Dr. J. W. Whittick for his note on histological changes in case 5.

QUEEN MARY'S HOSPITAL FOR CHILDREN, CARSHALTO
SURREY

The cerebral palsy unit at Queen Mary's Hospital Children, Carshalton, was the first unit in the Brit Isles set up specifically for the treatment of children wit this condition.[1] Since other units have been, or are bein established in this country, an account of some of o experiences may be of value.

At first, children up to the age of 16 years w accepted; but, though the results were encouraging became evident that the earlier the child was treated better was the result obtained. Later we concentrated children under the age of 5 years, but again it became apparent that the youngest age-groups trea gave the more promising results; so now we try to the children under the age of 6 months. Unfortunately it is commonly taught that cerebral palsy is not rec le until the child is aged 2 years or even more. xperience has taught us that it can be recognised before that, and when all such children are recog- and treated in infancy it should be possible to nt much of the deformity now associated with al palsy. We have therefore concentrated here on gns that should lead one to suspect the disorder in s.

---

[1] Collis, E. *Lancet*, 1947, ii, 230.

NATURE OF CEREBRAL PALSY

ebral palsy is often regarded as an orthopædic tion, largely because the children are not dealt with deformities have become established. It should be d that cerebral palsy is primarily a neurological tion in that damage has been done to the cerebral , the basal ganglia, or the cerebellum, and conse- ly the normal motor paths—the upper motor nes—are disorganised. There is initially no abnor- y of the muscle-fibres—the muscles can function lly if normal stimuli are sent to them. This view of athological changes must be constantly borne in if we are to adopt the proper methods of diagnosis reatment. In order to diagnose cerebral palsy in its st stages, therefore, we have constantly to compare actions of a normal baby with those of a baby with al palsy.

ormal baby's movements in the first month or two voluntary. In due course their place is taken by tary movements. The normal baby's brain con- y receives external and internal stimuli which help uild up a mental picture of motor action and hence te movement to effect the particular action shown in picture; and the movement produced supplies r stimuli. A baby who does not receive these li, owing to the cutting off of the motor paths, t make a complete mental picture and consequently t attempt the complete appropriate movements. this baby does receive stimuli he tries to make ovements by damaged or other paths; so the ments are abnormal. Once one can get the baby ild up a mental picture of the movement required, an show him what the movement should be, he ompensate with the motor paths he has which will e him to perform the motor acts more or less ally though perhaps imperfectly.

ÆTIOLOGY

phyxia.—Evans[2] found a history of asphyxia in cases of cerebral palsy. In most of our cases too was a history of blue asphyxia at birth; in a few was a history of asphyxia pallida. There may be a history of difficult labour, but not infrequently abour was precipitate or premature. A history of ical injury at birth was uncommon.

esus Factor.—We thought at one time that cases o this factor might be treatable, but in the very few we have seen the child was so mentally deficient make the cerebral palsy untreatable.

DIAGNOSIS OF SPASTIC CEREBRAL PALSY

uscles Affected.—In cerebral palsy we are apt to k that it is only the muscles of the limbs that are ted; but, since cerebral damage is the prime cause he palsy, it follows that, unless the damage is very h restricted, the greater part of the whole muscular em is involved. Among the muscles affected are e concerned with swallowing, the muscles of the eye other muscles of the head and neck, the muscles of iration, and those of the upper and lower limbs. The gue is often slow-moving and restricted in spastic ebral palsy, whereas in athetoid cerebral palsy it is gling and irregular in movement and uncontrolled. allowing is difficult in both types of cerebral palsy, baby dribbling from the corner of the mouth. The eye movements are restricted, with the result that the child does not direct its eyes towards objects held away from the midline; and interference with the ocular muscles may produce squint.

Hearing.—The child may be deaf, either completely or to certain tones, but in an infant this is very difficult to ascertain and is not likely to be of much help in diagnosis.

Sucking.—Since sucking is one of the first instinctive actions of the baby, any difficulty in feeding should be investigated, because it may be one of the first signs of cerebral palsy. Dribbling from the mouth after the first few months should suggest cerebral damage, but it should not be forgotten that dribbling is common in mentally defective children.

Smiling.—One of the first actions of a baby is to smile, which he should begin to do at the age of 4–6 weeks, and smiling should be well developed by the age of 2 or 3 months. If the baby does not smile or is slow to smile, cerebral palsy should be suspected. Mentally defective babies, on the other hand, generally smile very easily.

Development.—In comparing the development of a normal baby with that of one with cerebral palsy we are indebted in our statements about the normal baby very largely to Aldrich[3] among others, but independently one of us (E. C.) has been making observations on the same subject for many years. Aldrich points out that, when a baby aged 3 months is picked up, his head may come up with him without dropping back; many babies at that age can balance their heads on their shoulders. When a baby aged 3 months with cerebral palsy is picked up, the head will probably drop back. At 4 months a normal baby begins to learn control of his arms and legs and to grasp things, whereas the baby with cerebral palsy gives no evidence that he is learning control. At 6 months a normal baby may be trying to sit up and, when sat up, stretches out his arms; from that age onwards he starts trying to move round, first learning to kick his legs and slowly trying to crawl round his cot, eventually trying to pull himself up by the sides of the cot until he can stand a little holding on, and next trying to walk. A baby of 6 months with cerebral palsy cannot do these things if the lesion is severe; if it is less severe, movement is limited and delayed in development, particularly movement of the legs. The mother is naturally the person who first observes these movements or the lack of them; therefore she should be closely questioned about them.

Aversion of Head while Prone.—After the age of 6 months a normal baby tries to see what is going on round him, he tries to crane his neck to see things, and he tries to roll over, whereas a baby with cerebral palsy lies helpless and cannot crane his neck, roll over, or, if prone, avert his head. Such a child may be suffocated owing to this inability to turn his head while prone.

Grasp.—As pointed out above, grasp at first is a reflex action; if one puts a finger into each fist of a baby aged less than 3 months one can lift him because of the reflex action. When a little older the baby will let go if lifted in this way. A baby with cerebral palsy can still be lifted by the clenched fists some weeks or months after the age of 3 months, not only because the clenching of the fists is a reflex action, but also because he cannot let go, owing to lack of voluntary control of the muscles.

Flexion of Knees on Lifting.—If one holds up a normal baby aged 6–12 months by grasping him under the armpits, he tends to flex the knees and hips, whereas a baby with cerebral palsy, when so lifted, keeps the legs straight, possibly crossed, and perhaps with the toes pointing downwards.

Abduction of Legs.—It is easy to abduct the legs of a normal recumbent infant of 6 months, but it may be difficult to abduct, in the same conditions, those of a baby with cerebral palsy. Even when the palsied baby congested but otherwise normal. All bronchi were congested, those on the right being filled with mucopus. The trachea was slightly congested and contained much mucopus. Histologically the pneumonia showed unusual features. It was diffuse and yet unlike either classical lobar pneumonia or confluent bronchopneumonia. In the early stages the reaction was notably œdematous. In the fully developed lesion there were many mononuclear cells in the exudate, and the interstitial connective-tissue was widened by inflammatory changes. There was a relative scarcity of neutrophil polymorphs and fibrin. This picture resembles that of a fatal case of Q fever described by Lillie et al. (1941). The absence of food particles and of suppuration excludes the possibility of inhalation pneumonia, and the reaction is unlike that of lipoid pneumonia.

[3] Aldrich, C. A. Rochester Child Health Progress Bulletins. Rochester, Minn., 1949.

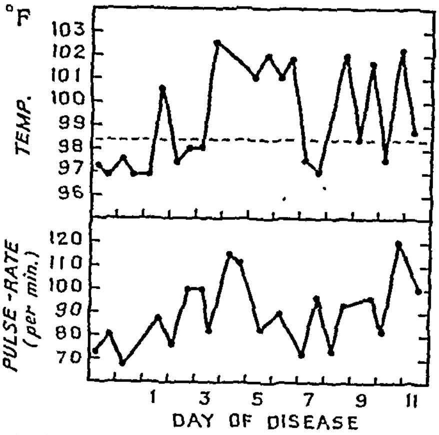

Fig. 3.—Temperature and pulse-rate in case 5.

Preliminary attempts to find rickettsiæ by a modified Giemsa method show minute pink coccoid bodies which may be of significance. A fuller description will appear elsewhere.

Bronchopneumonia was expected, and nothing unusual was suspected when it developed. Q fever did not break out in the hospital until over two weeks after this patient's death. Retrospectively, however, it is presumed that he had Q fever, on the following grounds: (1) the histological changes in the lung; (2) the serological evidence of infection in his wife (case 6), who had never visited the Royal Cancer Hospital but, like the patient himself, is known to have been in contact with an endemic focus at their home on the south-east coast; and (3) the link afforded by this patient between this focus and the hospital cases. Detailed epidemiological evidence will be presented in a further publication.

Case 6.—In this patient, the wife of case 5, there is no reliable history of recent fever. A complement-fixation test for *R. burneti* antibodies showed full fixation at 1/320 and 50% fixation at 1/640.

Case 7.—The patient, a physicist, aged 40, suddenly felt weak and feverish at 11 A.M. on Sept. 7. He carried on but spent a restless night. The next day he tried to work but was admitted to hospital. He felt hot and "swimmy," with slight aching in bones and joints. There was no constant headache, but "the top of my head lifts off if I cough." He ran a fever of 100–103°F for three days, after which the temperature fell by lysis. The fever had lasted altogether five days. He had rigors and drenching sweats though his fever at no time was very high. The pulse-rate was constantly 70–80 per min.

Slightly tubular breathing and faint tissue-paper crepitations were heard at the left lung base on Sept. 8. X-ray examination showed no abnormality. On Sept. 10 the total white-cell count was 10,400 per c.mm.

He returned to work on Oct. 3 but did not feel fit until two weeks later; meanwhile he felt "woolly" in the head, could not concentrate, got palpitations and went hot with exercise, and his legs felt too dead to move.

The titre of complement-fixing antibodies for *R. burneti* was less than 1/5 on Sept. 9, but had risen to 1/40 to 1/80 by Oct. 7.

Case 8.—This patient, aged 29, is the wife of case 7. On Sept. 9 she suddenly had rigors and fever. She could not sleep that night and had big sweats. There was pain at the bottom of the spine and "a colossal throbbing" in the back of the head. The worst day was Sept. 11. The temperature was 104°F on the 12th, when she was still having sweats. On the 13th some fine crepitations were heard at both bases. She continued like this until the 17th when she started to get up; she was fully up by the 21st but only "crawling round" and feeling ill. The fever had lasted probably nine days. By Oct. 18 there were no signs in the the radiographic appearance was normal. The complained, however, of headache, a rattling depression.

The titre of complement-fixing antibodies for *R.* was less than 1/10 on Sept. 12, *and rose to 1/80 on the*

Both cases 7 and 8 were moderately severe and in convalescence. A clinical diagnosis of Q was though no connexion could be traced with the other They would have excited no particular comment if had not been on the look-out for more cases.

DISCUSSION

Now that Q fever has appeared in England, it well be asked what importance it has for the prac physician. This question cannot be answered until frequency here has been judged by serological sur of likely cases. The most promising field is among the term fevers passing under vague titles such as " or among longer fevers such as "atypical monia." No explosive outbreaks or fevers pecul handlers of cattle or sheep, or of their products, have noticed in this country; but serological tests ma show that infection of this group has in fact taken Relapsing and chronic cases would be partic important to the physician because, if undiag they would cause considerable difficulty and an Yet the diagnosis of Q fever can easily be confirmed refuted, because the complement-fixation test beco positive 7–12 days after the onset of fever.

SUMMARY

The clinical features of Q fever are described.

Eight cases arising in England are reported.

I wish to express my thanks to Dr. E. G. Lewis for her with the cases, and to Dr. J. W. Whittick for his note on histological changes in case 5.

CHIEF CEREBRAL PALSY THERAPIST

QUEEN MARY'S HOSPITAL FOR CHILDREN, CARSHAL
SURREY

The cerebral palsy unit at Queen Mary's Hospital Children, Carshalton, was the first unit in the Bri Isles set up specifically for the treatment of children w this condition.[1] Since other units have been, or are bei established in this country, an account of some of experiences may be of value.

At first, children up to the age of 16 years accepted; but, though the results were encouragin became evident that the earlier the child was treated better was the result obtained. Later we concentrat children under the age of 5 years, but again it became apparent that the youngest age-groups tr gave the more promising results; so now we try to the children under the age of 6 months. Unfortuna it is commonly taught that cerebral palsy is not re e until the child is aged 2 years or even more. xperience has taught us that it can be recognised efore that, and when all such children are recog- and treated-in infancy it should be possible to at much of the deformity now associated with al palsy. We have therefore concentrated here on ns that should lead one to suspect the disorder in s.

---

[1] Collis, E. *Lancet*, 1947, ii, 239.

NATURE OF CEREBRAL PALSY

ebral palsy is often regarded as an orthopædic ion, largely because the children are not dealt with leformities have become established. It should be d that cerebral palsy is primarily a neurological ion in that damage has been done to the cerebral , the basal ganglia, or the cerebellum, and conse- y the normal motor paths—the upper motor nes—are disorganised. There is initially no abnor- of-the muscle-fibres—the muscles can function lly if normal stimuli are sent to them. This view of athological changes must be constantly borne in if we are to adopt the proper methods of diagnosis eatment. In order to diagnose cerebral palsy in its t stages, therefore, we have constantly to compare ctions of a normal baby with those of a baby with al palsy.

ormal baby's movements in the first month or two voluntary. In due course their place is taken by ary movements. The normal baby's brain con- y receives external and internal stimuli which help uild up a mental picture of motor action and hence e movement to effect the particular action shown in picture; and the movement produced supplies r stimuli. A baby who does not receive these i, owing to the cutting off of the motor paths, t make a complete mental picture and consequently t attempt the complete appropriate movements. this baby does receive stimuli he tries to make novements by damaged or other paths; so the nents are abnormal. Once one can get the baby ld up a mental picture of the movement required, an show him what the movement should be, he ompensate with the motor paths he has which will him to perform the motor acts more or less lly though perhaps imperfectly.

ÆTIOLOGY

hyxia.—Evans[2] found a history of asphyxia in cases of cerebral palsy. In most of our cases too was a history of blue asphyxia at birth; in a few was a history of asphyxia pallida. There may be history of difficult labour, but not infrequently bour was precipitate or premature. A history of cal injury at birth was uncommon.

sus Factor.—We thought at one time that cases this factor might be treatable, but in the very few we have seen the child was so mentally deficient make the cerebral palsy untreatable.

DIAGNOSIS OF SPASTIC CEREBRAL PALSY

scles Affected.—In cerebral palsy we are apt to that it is only the muscles of the limbs that are ted; but, since cerebral damage is the prime cause e palsy, it follows that, unless the damage is very restricted, the greater part of the whole muscular m is involved. Among the muscles affected are concerned with swallowing, the muscles of the eye other muscles of the head and neck, the muscles of iration, and those of the upper and lower limbs. The ue is often slow-moving and restricted in spastic bral palsy, whereas in athetoid cerebral palsy it is gling and irregular in movement and uncontrolled. llowing is difficult in both types of cerebral palsy, baby dribbling from the corner of the mouth. The eye movements are restricted, with the result that the child does not direct its eyes towards objects held away from the midline; and interference with the ocular muscles may produce squint.

Hearing.—The child may be deaf, either completely or to certain tones, but in an infant this is very difficult to ascertain and is not likely to be of much help in diagnosis.

Sucking.—Since sucking is one of the first instinctive actions of the baby, any difficulty in feeding should be investigated, because it may be one of the first signs of cerebral palsy. Dribbling from the mouth after the first few months should suggest cerebral damage, but it should not be forgotten that dribbling is common in mentally defective children.

Smiling.—One of the first actions of a baby is to smile, which he should begin to do at the age of 4–6 weeks, and smiling should be well developed by the age of 2 or 3 months. If the baby does not smile or is slow to smile, cerebral palsy should be suspected. Mentally defective babies, on the other hand, generally smile very easily.

Development.—In comparing the development of a normal baby with that of one with cerebral palsy we are indebted in our statements about the normal baby very largely to Aldrich[3] among others, but independently one of us (E. C.) has been making observations on the same subject for many years. Aldrich points out that, when a baby aged 3 months is picked up, his head may come up with him without dropping back; many babies at that age can balance their heads on their shoulders. When a baby aged 3 months with cerebral palsy is picked up, the head will probably drop back. At 4 months a normal baby begins to learn control of his arms and legs and to grasp things, whereas the baby with cerebral palsy gives no evidence that he is learning control. At 6 months a normal baby may be trying to sit up and, when sat up, stretches out his arms; from that age onwards he starts trying to move round, first learning to kick his legs and slowly trying to crawl round his cot, eventually trying to pull himself up by the sides of the cot until he can stand a little holding on, and next trying to walk. A baby of 6 months with cerebral palsy cannot do these things if the lesion is severe; if it is less severe, movement is limited and delayed in development, particularly movement of the legs. The mother is naturally the person who first observes these movements or the lack of them; therefore she should be closely questioned about them.

Aversion of Head while Prone.—After the age of 6 months a normal baby tries to see what is going on round him, he tries to crane his neck to see things, and he tries to roll over, whereas a baby with cerebral palsy lies helpless and cannot crane his neck, roll over, or, if prone, avert his head. Such a child may be suffocated owing to this inability to turn his head while prone.

Grasp.—As pointed out above, grasp at first is a reflex action; if one puts a finger into each fist of a baby aged less than 3 months one can lift him because of the reflex action. When a little older the baby will let go if lifted in this way. A baby with cerebral palsy can still be lifted by the clenched fists some weeks or months after the age of 3 months, not only because the clenching of the fists is a reflex action, but also because he cannot let go, owing to lack of voluntary control of the muscles.

Flexion of Knees on Lifting.—If one holds up a normal baby aged 6–12 months by grasping him under the armpits, he tends to flex the knees and hips, whereas a baby with cerebral palsy, when so lifted, keeps the legs straight, possibly crossed, and perhaps with the toes pointing downwards.

Abduction of Legs.—It is easy to abduct the legs of a normal recumbent infant of 6 months, but it may be difficult to abduct, in the same conditions, those of a baby with cerebral palsy. Even when the palsied baby is held upside down by his legs, abduction of his thighs is still limited.

---

[2] Evans, P. R. *Arch. Dis. Childh.* 1948, 23, 213.

[3] Aldrich, C. A. Rochester Child Health Progress Bulletins. Rochester, Minn., 1949.

Inversion.—When a normal baby is held upside down by the legs, his arms drop and his head reflexly extends, whereas if a baby with cerebral palsy is so held, his arms do not drop, or possibly only one drops, and his head does not extend.

Stretch Reflex.—If a forearm of a baby aged more than 3 months is passively flexed on the upper arm and then sharply extended it moves freely, whereas in cerebral palsy the forearm seems to resist extension. If a leg is flexed on the thigh and sharply extended, a similar resistance is obtained in cerebral palsy of the spastic type. This stretch reflex persists and can be elicited even when the child has been trained to use his limbs normally; we do not yet know whether it eventually disappears.

Retention of Fœtal Characteristics.—A normal baby aged 6–12 months, if sat up, has a straight back, but a baby of that age with cerebral palsy tends to retain the fœtal position with a curved back, and this may persist until the child is 3 or 4 years old or even later.

DIAGNOSIS OF ATHETOID CEREBRAL PALSY

In the athetoid type of cerebral palsy the signs are somewhat different. Since there is no spasticity, some of the signs described above are absent, but instead there are athetoid movements when the child tries to do anything. In the tension athetoid type muscular tension may be mistaken for spasticity but it is not continuous; if one watches carefully, the tension relaxes, and the limbs can then be moved easily. The wriggling irregular movements of the tongue, which have already been mentioned, may prevent the child from swallowing properly, sucking, or speaking, and thus cause dribbling from the corner of his mouth. Similar lack of control of other muscles prevents aversion of the head in the prone position. Abduction of the legs is easy, unless there is tension; the stretch reflex is not present; but the head is not extended when the child is inverted.

The variation of these signs in the athetoid makes diagnosis more difficult in athetoids than in spastics. In our experience athetoids do not show spasticity, and spastics do not show athetoid movements, but other workers do not agree that this division is always so clear-cut.

SOME OTHER TESTS

Other infantile reflexes besides those already mentioned can be tested.

Moro or Startle Reflex.—The infant's reaction to a sudden loud noise or other stimulus is noted. A normal baby quickly abducts its arms and legs and then bows them, but this gets less as the baby grows and becomes restricted to a body jerk at the age of 6 months or so, whereas in cerebral palsy the reaction persists undiminished owing to lack of muscular control. This sign is not of such practical use as those described above, because some conditions—e.g., deafness—prevent any reaction.

Neck-righting Reflex.—When the head is turned, the body normally turns as well. In cerebral palsy this reflex may be present, but equally it may be absent.

Tonic Neck Reflex.—There are two types of this: asymmetrical, in which, when the face is turned to one side, the opposite arm adducts and flexes; and symmetrical, in which, when the head is bent, the arms come forward. These are reflexes in the infant and are modified when voluntary movement is established. In cerebral palsy, especially the spastic type, they tend to persist.

Creeping Reflex.—When a normal infant under the age of 6 months, who has not yet reached the crawling stage, is placed prone and the sole of one of his feet is gently pushed, he usually draws up that leg, and sometimes the opposite arm, and projects his body When a child reaches the crawling stage, this gradually disappears, being superseded by movements. In spastic cerebral palsy this reflex persist for some time after it should have been m

Our experience with these tests is that, interesting, they do not give such practical diagnosis as those we have described.

DIFFERENTIAL DIAGNOSIS

Where there is damage to the motor areas or mo paths there is motor disability, and though, stri speaking, the term "cerebral palsy" should co any motor disability due to cerebral damage, it is u to describe a particular variety of motor disabilities, s in diagnosing the condition we have to distinguish t variety from others. Broadly speaking, the ch conditions from which it has to be distinguished mental deficiency with consequent motor disability, a amyotonia congenita.

Mental Deficiency.—Amentia causes motor disab but in mentally deficient infants, though spasticity seem to be present the child smiles, the tongue ments are free, the limbs are relaxed at times, and is free voluntary movement. Such an infant may unable to sit up, but when he is lying down he does convey the impression of fixity characteristic of spa cerebral palsy, or the wriggling jerky movements athetoid cerebral palsy. About 25% of children w cerebral palsy are mentally deficient, but in these ca the mental defect is added to the physical palsy, practical purposes we may take it that mental defe only associated with the spastic type of cerebral p

We do not wish to convey the impression that diagn in these cases is easy. In our cerebral palsy unit at Q Mary's Hospital for Children we admit every child f probationary period of up to three months, becau an infant whose physical movements are so limited in an older child who cannot speak, it is often extr difficult to assess the mental condition, but the gr our experience the easier are we finding it to do so.

Amyotonia congenita should not cause much diffic It is relatively rare and the disability is a loss of p rather than spasticity or athetosis. The voluntary m ments are present but weak; the reflexes are dimini or absent; and such movements as these children make are characterised more by the flexibility o body than by rigidity. In very young infants the nosis might be difficult at first, but if they are kept observation for a short time any doubt should be reso

TREATMENT

The importance of the early recognition of ce palsy is that, when the condition is recognised ear results of treatment are superior to those obtained the disorder is only recognised at a later age. The ment must be individual and be related to the e cause of the condition. The treatment of spasticity be different from that of athetosis, and the treatm of the ataxic type different from either.

CONCLUSIONS

The treatment of cerebral palsy is most succes when it is started in early infancy.

It is usually possible to diagnose cerebral palsy be the child is six months old.

The points to look for are: absence or very development of control of the facial and throat mus shown by lack of smiling; difficulty in swallow dribbling; slow stiff movements of the tongue; movements of the eye, and squint; deafness; clench of the fingers with apparent inability to open the irregular movements of the arms; inability of the ch to alter its position when lying down; and lack of l movements of the lower limbs. At the age of 6–12 ths the affected child does not attempt to crawl or imb up in his cot, and the normal flexing of the s is absent. As the child gets older this picture of r disability becomes clearer, until at the age of urs it is so clear that few people cannot recognise it. 25% only of cases of spastic cerebral palsy mental iency is added to the physical disability.

A SUGGESTED METHOD FOR THE IRATION OF CERTAIN ANTIBIOTICS

eming and Smith (1947) have described the estima- of penicillin in serum using a culture medium posed of serum water, glucose, and an indicator, ol red; where growth occurs the sugar is fermented, indicator turns from red to yellow, and the serum ins are precipitated. A similar technique for the ation of streptomycin was used by May et al.). Experiments with these two antibiotics show at that the end-point in such titrations of streptomycin ch sharper than in those of penicillin. This is to be cted from the work of Abraham and Duthie (1946) showed that an acid agent such as penicillin is more e in a relatively acid medium whereas the reverse e of a base, such as streptomycin; when the organ- grows and acid is formed, penicillin will become and streptomycin less effective, with the result the end-point with penicillin is poorly defined but of streptomycin is sharp. 'Aureomycin,' a base, is ception to this rule (Paine et al. 1948), possibly se of its more rapid destruction in alkaline solution. the titration of penicillin is to depend on the change lour of an indicator, it is clearly desirable that when th takes place the reaction should become more line, and it seemed possible that the addition of urea e medium might give the required result if a sensitive nism producing urease could be found to release onia from the urea. Fortunately the Oxford staphy- ccus proved to be suitable, and it has been used in all tests to be described.

periment showed that concentrations of urea of 5% or more in broth acidified to pH 6·5–6·8 yielded gh ammonia after overnight incubation to give a tion of pH 8·3 or more, thus traversing the range of ol red, and in practice 0·5% urea has been used. a tends to break down in the autoclave, but steaming es only a minor rise in pH—which might, however, influence slightly the result of an accurate titration of a standard solution. The size of the inoculum is of greater significance, since on it depends the amount of urease carried over from the parent culture; in practice 0·1 ml. of overnight broth culture has been added to 10 ml. of urea broth, giving a final concentration of 1 in 200 after mixing in equal volume with the dilutions of penicillin in water or saline. These minor disadvantages disappear for practical purposes in the usual titration where the concentration in serum or body fluid is matched against a standard; it should be noted, however, that undiluted serum is alkaline enough to affect the reaction of the broth, and its reaction should therefore be adjusted where low concentrations of penicillin are to be expected.

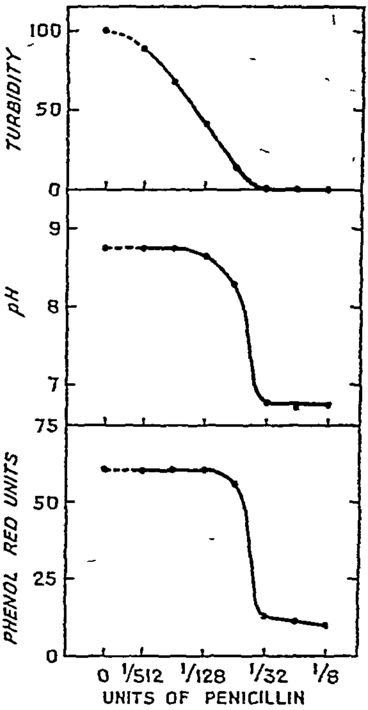

Fig. 1—Staphylococcus medium with increasing amounts of penicillin.

The table shows the results of titrations of penicillin and aureomycin solutions in serum water containing glucose and phenol red, in nutrient broth, and in acidified broth containing 0·5% urea and phenol red. The stated concentrations of the drugs fall by one-third from tube to tube but are otherwise only nominal, especially in the case of aureomycin, since accurately standardised solutions were not available. The readings were based on colour change and protein precipitation in the serum-water series, on turbidity in the broth tubes, and on colour change in the urea-broth series. It will be obvious that the end-point with both drugs is much sharper in the urea-broth series than in the others; we would suggest that the interval showing the greatest change should mark the end-point, giving readings in this case of $^1/_{27}$ unit of penicillin and 0·8 µg. of aureomycin. It may be of interest that after another day's incubation the end-point with aureomycin was clear-cut at 2·7 µg. in the urea-broth series but unreadable in the others.

RESULTS OF TITRATION OF PENICILLIN AND AUREOMYCIN IN VARIOUS CULTURE MEDIA

Culture medium	Penicillin (units per ml.)								
	$^1/_8$	$^1/_{12}$	$^1/_{18}$	$^1/_{27}$	$^1/_{40}$	$^1/_{60}$	$^1/_{90}$	$^1/_{135}$	0
ose serum water * ..	–	–	±	+	++	++	+++	Not done	++++
th	–	–	–	–	±	+	++		++++
a broth	–	–	–	±	+++	++++	++++		++++

Culture medium	Aureomycin (µg. per ml.)								
	4	2·7	1·8	1·2	0·8	0·53	0·35	0·23	0
cose serum water ..	Trace	Trace	±	±	+	+	++	++	++++
oth	–	–	±	+	+	++	++	+++	++++
a broth	–	–	–	–	+	+++	++++	++++	++++

* Glucose broth gives a sharper end-point than serum water with the Oxford staphylococcus as test organism.

This suggests that the acidity of the medium is of value in maintaining the activity of the drug, although the shift in the end-point underlines the importance of the size of the inoculum and the length of incubation in titrating bacteriostatic agents such as aureomycin or 'Chloromycetin.' The latter drug, incidentally, being neither acid nor base, can be titrated with apparently similar results in either medium.

Fig. 1 shows three curves obtained from a titration of penicillin in the presence of urea, the concentration being halved in successive tubes. Turbidities, expressed as a percentage of the control, were measured by a photo-electric absorptiometer at a wave-length of 650 mμ and pH values were obtained by means of the glass electrode. Estimations of the colour change of phenol red were made as follows: the medium was centrifuged at 4800 r.p.m. for 5–10 minutes in an angle centrifuge; to 3 ml. of the clear supernatant was added 1 ml. of phenol-red solution (saturated aqueous phenol red diluted 1 in 10), and the colour was determined in arbitrary "red units" by means of a photo-electric absorptiometer using Ilford Filter no. 606 (Spectrum Yellow). The turbidity curve approaches a straight line, starting at $^1/_{32}$ unit and increasing to $^1/_{512}$ unit where growth is almost as heavy as in the control. The other two curves show that the change in reaction, due to the production of ammonia, occurs mainly between $^1/_{32}$ and $^1/_{64}$ unit and ceases at pH 7·75.

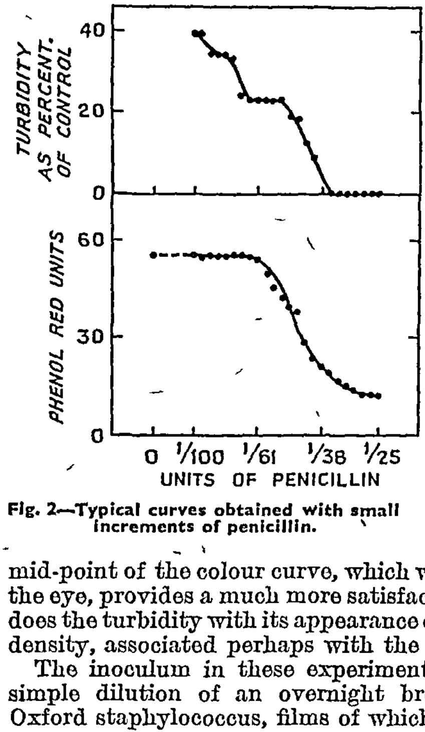

Fig. 2—Typical curves obtained with small increments of penicillin.

Fig. 2 illustrates a more elaborate titration with a fall in the concentration of the drug of about 6% from tube to tube. The mid-point of the colour curve, which was clearly visible to the eye, provides a much more satisfactory end-point than does the turbidity with its appearance of steps of increasing density, associated perhaps with the change in reaction.

The inoculum in these experiments was obtained by simple dilution of an overnight broth culture of the Oxford staphylococcus, films of which show considerable clumping—enough probably to account for minor variations which have been seen in duplicated titrations. Where a high degree of accuracy is required, it would be necessary to find a sensitive strain less apt to form clumps and to remove such clumps as might be present. Not all strains of staphylococcus produce urease freely, the Oxford staphylococcus being unusually active in this respect. The hæmolytic streptococcus which is commonly used as test organism in the serum water and glucose medium does not appear to break down urea. The growth phase of the parent culture, the period of incubation, the size of the inoculum, the percentage of urea, and the primary reaction of the medium would also need consideration.

DISCUSSION

Mitchison et al. (1949) have drawn attention to the inaccuracies liable to occur in the routine use of the micro-method described by May et al. (1947) for the titration of streptomycin in serum. Venepuncture, however, in skilful hands, though more nuisance to the operator, is little more distressing to the patient than a finger-prick, and the larger volume of serum more accurate measurement by graduated pi test-tubes. Further, with a sharp end-point such obtained with a glucose medium and streptom with urea broth and penicillin or aureomycin, differences between successive tubes in the con titration of the standard solution might be con reduced and thus remove one source of error.

SUMMARY

A method is described for the accurate titratio antibiotics, such as penicillin and aureomycin, which more active in acid than alkaline solution.

ADDENDUM.—Experience has shown that serum, from its slight buffering action, interferes to some e with either the production or the activity of urease therefore advisable to use 20% serum water in making dilutions of the standard solution and of serum under te

RETICULOCYTE RESPONSE TO LIVE THERAPY IN PERNICIOUS ANÆMIA

J. KOHÁRI-KUCHÁRIK
M.D. Budapest
LECTURER IN MEDICINE, UNIVERSITY OF BUDAPES

IN pernicious anæmia one of the first signs of incre production of red cells after liver therapy is a increase in the number of reticulocytes in the circula blood. The degree of this reticulocyte response crisis, is inversely proportional to the *initial* red count—i.e., the lower the initial red-cell count greater is the reticulocyte response. Many workers tried to find a formula for this relationship; the known is that of Riddle (1930).

Though the clinical value of such formulæ has been disputed, especially by Murphy (1936), they to be still accepted. Failure to reach the expected re locyte peak is often regarded as a warning either of inaccuracy of the diagnosis or of the unreliabilit the liver preparation used. I have therefore exa anew the published reports which seem to support reliability of these formulæ, and investigated personal cases.

INVESTIGATION

Of 75 patients admitted with a diagnosis of pernic anæmia 47 afforded sufficient hæmatological data, suc daily red-cell and reticulocyte counts for at least a m

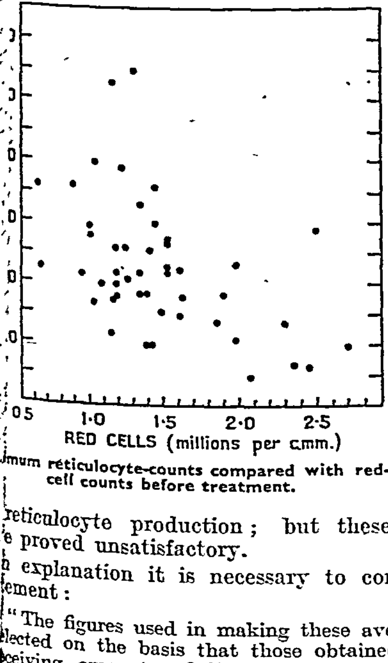
ther selection was made. The diagnosis was estab-l on blood-counts, bone-marrow biopsy, histamine-tory achlorhydria, and, last but not least, the icial effect of liver therapy. After a single large (20 ml.) of liver extract ('Exhepar' Certa, or ipolon' Bayer) red-cell and reticulocyte counts made daily. The results are summarised in table I compared with those of Minot et al. (1928), Murphy i), and Zerfas (1931) in table II.

DISCUSSION

ree-quarters of our results do not correspond to standards of Riddle (1930). When the results are ed as in the accompanying figure, there is no ablance either to a parabolic or to a hyperbolic curve. Several attempts have been made to correct Riddle's and other formulæ by considering the duration of the reticulocyte response. One proposal was to multiply the number of days by the observed reticulocyte-count, thus expressing the "volume" reticulocyte production; but these modifications e proved unsatisfactory.



mum reticulocyte-counts compared with red-cell counts before treatment.

n explanation it is necessary to consider Riddle's ement:

> "The figures used in making these average values are lected on the basis that those obtained from patients ceiving amounts of liver inadequate to produce an fective response, and those from patients in whom some hibiting factor obviously prevented a typical response, ere not used in compiling these statistics."

Riddle's use of the term "maximal response" implies, highest results only were taken into account, which quite permissible so long as this meaning of "maximal sponse" is kept in mind. There is good reason to ppose that even Riddle did not intend that his formula ould show what reticulocyte response is to be looked r in the average case encountered in practice; his rmula seems to have slipped into the textbooks as a sult of a misunderstanding of the meaning of "maxi-al" value, which was intended to represent the optimal apacity of the bone-marrow in *certain* cases. This aximal response cannot be expected in clinical practice. or instance, in cases with an initial red-cell count between 1,200,000 and 1,400,000 per c.mm. the following reticulocyte maxima were found: 10%, 12%, 18%. 20%, 22%, 22% (twice), and 26%; only two cases reached the predicted standard of 32% and 39%, their maxima being 52% and 55%. Though American liver preparations stimulate higher reticulocyte responses per unit dose, the range of variation reported with them is similar to that obtained in Europe. In table II data from the Eli Lilly laboratory (Zerfas 1931) are compared with our findings, and it can be seen that there is no substantial difference in reticulocyte response between patients with an initial red-cell count less than 1,000,000 per c.mm. and those with 1·2, 1·4, or 1·6 million per c.mm., so that the reticulocyte response plotted against the initial red-cell count will not give any curve.

Our biological experience teaches us that body functions are all subject to variation. Reticulocytes are the new red cells produced from pro-erythroblasts or megaloblasts on the administration of certain hæmopoietic factors stored in the liver. The anatomical extent of the bone-marrow and the rate of cell maturation cannot be accurately predicted, and are subject to wide variation. Therefore the reticulocyte response cannot be determined by the red-cell count before the administration of liver, because the initial red-cell count bears no relation to the quantity and quality of the bone-marrow. If there were any such relation, the magnitude of reticulocyte response would be a mere question of dilution. For instance, if everybody's bone-marrow always contained an equal number of pro-erythroblasts or, in pernicious anæmia, promegaloblasts—say 5 billion (10^{12}) altogether—and if the number of fresh reticulocytes which are released at once into the circulation were, say, 50% of the promegaloblasts, then the reticulocyte-count in the peripheral blood, stated as a percentage of the red cells, would depend only on the number of red cells. On the figures postulated above, $2^1/_2$ billion reticulocytes should be related to various numbers of total red cells. This is certainly not the case.

SUMMARY

The maximum reticulocyte response to liver therapy in pernicious anæmia is subject to biological variations, but there is no significant difference in the response when the initial red-cell count is under 1 million or 1·2, 1·4, or 1·6 million per c.mm., so no strict formula can be devised which will forecast the response from the initial red-cell count. To avoid errors in diagnosis or in the assessment of liver extracts it is recommended that the customary average, rather than the maximum, reticulocyte response should be taken as the standard. With an initial red-cell count of below 1·6 million per c.mm. this seems to be about 20–30% with European, and 30–40% with American liver extracts.

ERYTHEMA MULTIFORME EXUDATIVUM

(THE STEVENS-JOHNSON SYNDROME)

ELLIS DRESNER
M.B. Durh.
MEDICAL REGISTRAR, POSTGRADUATE MEDICAL SCHOOL OF LONDON

Von Hebra, in 1860, isolated from other erythemata a malignant type of erythema multiforme characterised by erythemato-vesicular, bullous, or purpuric skin lesions, involvement of orificial membranes, and constitutional disturbances (von Hebra 1866). To this syndrome other clinicians early added bullous lesions in the mouth and oropharynx, ophthalmia ("herpes iris conjunctivæ," Fuchs 1876), and visceral and joint manifestations (Bazin 1862, Quinquaud 1882, Kaposi 1893, von Düring 1896, Osler 1895). Subsequent descriptions of the syndrome have appeared under different names, such as "ectodermose erosive pluriorificialis" (Rendu 1916), "eruptive fever with stomatitis and ophthalmia," ("Stevens-Johnson syndrome," Stevens and Johnson 1922), "dermato-stomatitis," (Baader 1925), and "mucosal respiratory syndrome" (Stanyon and Warner 1945).

Of recent years many cases of this syndrome have been reported, mostly from America but also from Scandinavia (Ustvedt 1948) and from this country (Dowling 1940, Sneddon 1947, Murray 1947, Nellen 1947, Johnstone 1947, Neale 1948). The published reports have been reviewed by Keil (1940), Lever (1944), and Soll (1947).

The following case, typical of erythema multiforme exudativum, is of interest because of the extraordinary severity followed by complete recovery, and the negative results of bacteriological investigations.

CASE-RECORD

A butcher's assistant, aged 27, was admitted to hospital on May 22, 1948. Fifteen days before admission he developed a sore throat with fever and sweating. He stayed in bed for three days, and during that time took 7 g. of sulphadiazine prescribed by his doctor. On the fourth day he returned to work feeling improved. Six days later he developed small "blisters" on the lips, tongue, and mouth, with malaise, frontal headache, and anorexia. During the next twenty-four hours purplish spots developed on the face, forearms, hands, and feet, and spread to the neck, shoulders, and thighs, and some became vesicular. The mouth was then very painful, and two days after the onset of the rash the patient complained of painful swelling of the right elbow. During the day before admission he became increasingly prostrated, with generalised abdominal discomfort, nausea and retching, and difficulty in swallowing. There was a dry cough, and the left knee and ankle became swollen and painful. Micturition was unaffected, and the bowels were slightly loose.

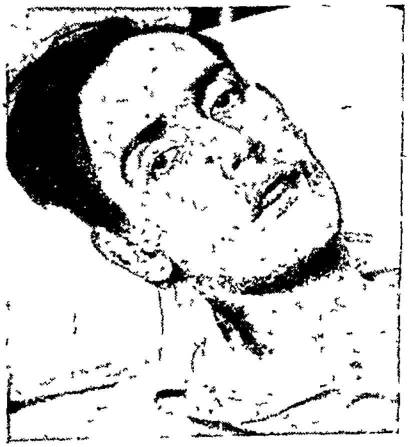

Fig. 1—Distribution of lesions on face.

On the day before admission a small nephew sleeping in the same room was admitted to an infectious diseases hospital with mild scarlatina, and three days later his brother-in-law, also living in the same house, developed a "septic sore throat"; but no bacteriological investigations were made.

Past History.—Apart from measles in infancy there had been no previous illness. By reason of his occupation the patient had been liable to minor sepsis of the hands and fingers, and had had an infection of the right fourth about four weeks previously, which healed in a few without specific treatment.

On examination the patient was a slim pale youn desperately ill and prostrate. Temperature 98·4°F, rate 128, respirations 20 per min. He had well fœtor oris and a recently healed paronychia on th fourth digit. Scattered over his face, neck, shoulder and legs were circular purplish-red circumscribed surrounded by a narrow zone of erythema (figs. 1 They were mainly on the extensor surfaces of the a the flexor surfaces of the legs, and were especially m on the buttocks. The trunk was clear, apart from tw in the right groin and on the scrotum. The vesicle from a few millimetres to more than a centimetre in d the larger ones lying over bony prominences, such elbows, metacarpophalangeal joints, and malleoli were not umbilicated and contained a thin sanguineo On the mucosa of the lips, palate, mouth, and phary numerous cherry-red macules on which were super small vesicles. Many were eroded. The lips were and bleeding, the tongue was coated, and there was a gingivitis. The pharynx and tonsils were injected, tonsillar glands were enlarged and tender. There other lymphadenopathy, and nothing abnormal was f examination of the cardiovascular, respiratory, and

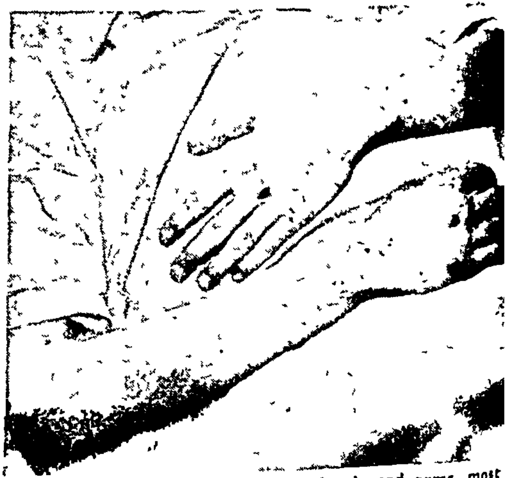

Fig. 2—Hæmorrhagic vesicles on hands and arms, most over joints.

nervous systems. The blood-pressure was 125/95 m The ocular fundi were normal. The abdomen was s the liver and spleen were impalpable. Effusions were in the left knee and ankle joints; and, though there swelling of the right elbow, movements there were r and painful. The other joints were normal.

Investigations.—The urine contained much protein otherwise normal. A blood-count showed red cells 6, per c.mm., Hb 118% (Sahli), white cells 21,000 per (neutrophils 72%, lymphocytes 14%, monocytes The bleeding-time and clotting-time were normal. C fragility was not increased (Hess test negative). Radi of the chest was normal.

Treatment and Progress (fig. 3).—Parenteral penicil given from the day of admission and was contin thirty-five days. Soluble sulphathiazole was also give muscularly from the second day, but was discontinue streptomycin therapy was begun. No new skin appeared, but some of the vesicles became pustular. oropharyngeal lesions became eroded, and small formed on them. Despite dysphagia the patient took by mouth, and these were supplemented by saline s given per rectum. Dysuria was complained of duri first week, but there was no urethral discharge.

May 25.—Streptomycin therapy was begun with a of 0·5 g. four-hourly. The skin lesions were drying, b sloughs were spreading and becoming confluent, and was profuse salivation. The mouth gave rise to consid anxiety in spite of constant attention. Joint ef were unchanged.

May 28.—The patient's condition had deteriorated. temperature was 101°F, with increased prostration

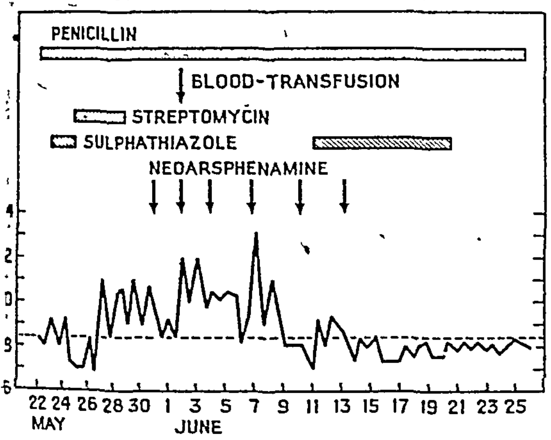

Fig. 3—Temperature chart and treatment.

ius. His mouth and throat now presented an alarming re, since the entire buccal mucosa, palate, and fauces concealed by a thick greyish-white adherent membrane, here was constant oozing of blood from the fissured lips. day this false membrane began to separate, leaving a bleeding surface, and the patient complained of severe ing retrosternal pain on swallowing. The joint effusions resolving. Streptomycin was discontinued, a total of having been given. During the next four days the erature continued elevated and irregular, with a disproonately high pulse-rate. Large sloughs separated from nouth, gums, and pharynx, with slight loss of tissue, and etrosternal pain continued. Large doses of nicotinamide, lavine, and ascorbic acid were administered.

ay 31.—Neoarsphenamine 0·15 g. was given intravenously lternate days. The patient had now developed râles at lung bases and a loose cough with increasing amounts tery sputum. Small amounts of fresh blood and melæna, traces of mucous and necrotic tissue, were passed per m, and his hæmoglobin level had fallen.

ne 2.—A transfusion of fresh blood was given, after h there was no more bleeding per rectum, but at this hæmorrhages and exudates were first noted in both r fundi.

ne 6.—All cutaneous lesions had crusted and fallen off, the condition of the mouth had much improved. The nt was taking solids by mouth but still salivated usly, and the amount of sputum was about 20 oz. daily.

ne 11.—There was definite consolidation of the right r lobe. Separation of sloughs from the mouth was now plete, leaving the oral mucosa friable and hyperæmic. hathiazole was given by mouth in gradually reduced s for the next ten days, by which time the consolidation resolved.

une 13.—The patient was afebrile, in spite of a severe ngitis lasting five days early in convalescence.

uly 22.—He was discharged, the only residua of the ss being deeply pigmented coppery spots at the sites of the larger skin lesions, and loss of the uvula, which had sloughed completely. These pigmented spots were still present when he was seen six months later, and some had central depressions covered by fine scars (fig. 4), but he was otherwise well and free from symptoms.

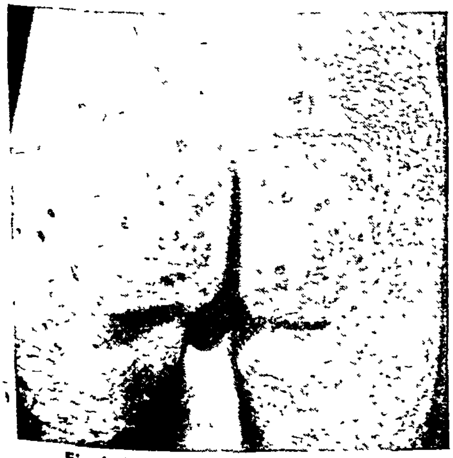

Fig. 4—Residual pigmentation and scars.

Laboratory Investigations.—The highest white-cell count after admission was 21,000 per c.mm. on June 1 (polymorphs 89%, eosinophils 1%, lymphocytes 7%, monocytes 3%); the eosinophils never rose above 2%. The heavy albuminuria noted on admission persisted until the patient was afebrile. Occasional red and white cells were noted a few times. The urine was sterile throughout.

Repeated attempts at culturing organisms from the blood, vesicle fluid, throat, and an excised skin lesion were negative or grew only contaminants. During the stage of pulmonary consolidation *Strep. pneumoniæ* and a penicillin-resistant *Staph. aureus* were found in the sputum. The blood Wassermann and Kahn reactions were negative, as also were serum agglutinations against the typhoid, paratyphoid, abortus, and salmonella groups, and the Paul-Bunnell and Weil-Felix reactions. The Strauss reaction and complement-fixation and conglutination tests for *Pf. mallei* were negative, and injection of vesicle fluid into a guineapig gave negative results. The blood-antistreptolysin titre was 60 units per ml. at the height of the illness.

Virus-neutralisation tests against herpes virus were done on the serum on two occasions: at the middle of the illness and early in convalescence. On both occasions there was a positive titre at 1/16, which was considered not significant.

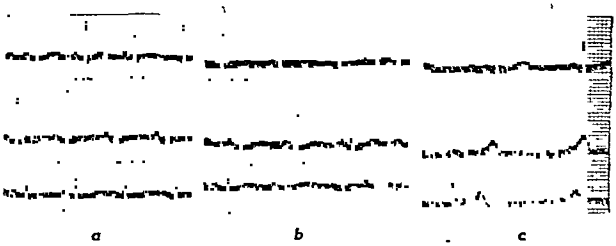

Fig. 5—Electrocardiograms (standard leads): *a*, June 9, 1948; *b*, June 17, 1948; *c*, July 20, 1948.

Histological examination of an excised cutaneous vesicle showed a non-specific inflammation, and no organisms or inclusion-bodies were seen.

Electrocardiograms (fig. 5): on June 9 the T wave was flat in all limb leads and chest leads; on the 17th the T wave was still iso-electric in leads II and III; and on June 30 the T wave was upright in all leads and of normal voltage.

DISCUSSION

To those unfamiliar with it this condition is puzzling and, as in the present case, leads to extensive laboratory investigations to establish a diagnosis. The differential diagnosis is discussed by Fletcher and Harris (1945).

The sudden onset of fever, sore throat, and exudative lesions of the skin and mouth, with progressive involvement of many orificial surfaces, and the extension to viscera, is characteristic of the severe type of erythema multiforme exudativum of Hebra. Of the features presented here the pseudomembranous oropharyngitis was perhaps the most striking. In contrast to the exanthem, it is the most constant feature of this disease, and Schwartz and Brainerd (1946) are of the opinion that the mouth lesion is so characteristic as to be patnognomonic. Though the exanthem varies in its morphology, the severe types of erythema multiforme exudativum are almost invariably associated with a vesiculo-bullous eruption, often hæmorrhagic, of the type seen in the present case, leaving residual pigmentation on healing. Cases with mucosal lesions and constitutional symptoms only and without a rash have been reported (Wentz and Seiple 1947, Grossman 1946). In the present case the eyes were not affected as they so often are (the so-called Stevens-Johnson syndrome), often with disastrous sequelæ. An unusual feature was the electrocardiographic changes suggesting a transient pericarditis (fig. 5). Electrocardiographic abnormalities are rarely reported in erythema multiforme exudativum. Changes of a non-specific nature were noted by Patz (1947) and Edgar and Syverton (1938), but pericarditis has not previously been reported.

The cause of this interesting condition is still obscure. The nature of the disease, with its abrupt febrile onset and self-limiting course, suggests an infection, but attempts to isolate a causal organism are always unsuccessful. The offending organism might be a virus, and known virus infections often accompany or immediately precede the disease; these include herpes simplex (Forman and Whitwell 1934), mumps (Edgar and Syverton 1938, Kove 1945), and primary atypical pneumonia (Stanyon and Warner 1945, Commission on Acute Respiratory Diseases 1946, Finland et al. 1948). Nevertheless, all virus studies and attempts to find a transmissible agent have been uniformly negative.

The possibility that erythema multiforme exudativum is a toxic drug reaction bears consideration, and there are an increasing number of cases in which drugs, and especially the newer chemotherapeutic agents, are incriminated, such as sulphonamides, phenobarbitone, phenolphthalein, 'Diasone,' phenytoin sodium, 'Tridione,' and even penicillin. In only one case has the drug-sensitivity hypothesis been fully substantiated. In Straus's (1948) case a severe attack of erythema multiforme exudativum with a bullous skin-rash, stomatitis, genital lesions, and purulent keratoconjunctivitis developed after the administration of 2 g. of sulphathiazole for chancroid. The patient recovered and, when he was well, sulphonamide sensitivity was tested by a passive transfer test in which 0·05 ml. of serum from a patient undergoing sulphadiazine therapy was injected intradermally. Two days later there was a severe recurrence of the illness exactly similar to the first attack, and the patient again recovered. Shortly afterwards he was given a test dose of 0·4 g. of sulphadiazine by mouth, and two days later he had a third attack of bullous erythema multiforme with ophthalmia and stomatitis as before. There is no doubt that in this case an illness indistinguishable from erythema multiforme exudativum was thrice provoked by sulphonamides.

Attention has recently been directed to the view that this syndrome is a hypersensitivity reaction, occurring in previously sensitised tissues. The sensitising allergens are probably multiple: bacterial, virus, food proteins, and drugs, the drugs acting as haptens and combining with serum-protein to form antigen. If this explanation is correct, erythema multiforme exudativum falls into the anaphylactoid group of diseases which includes the Henoch-Schoenlein group of vascular purpuras and erythema nodosum, with both of which it has features in common.

There are two possible factors in the ætiology of the present case. The patient had a febrile illness with sore throat about a week before the onset of the disease, and two contacts developed streptococcal infections. Treatment was with sulphadiazine, and either this, or the infection for which it was given, may have precipitated the illness. However, sulphonamides were repeated soon after admission and again in full doses later in the illness, without any exacerbation of his condition or recrudescence of the eruption, and can thus be excluded, leaving streptococcal infection as the probable allergen, though the eruption may have been provoked by sulphadiazine in a patient sensitised to a co-existing streptococcal infection (Doxiadis and McLean 1948).

There is no evidence that the antibiotics exhibited had any direct effect on the course of the disease, though they probably contributed to the ultimate recovery by the control of secondary infection.

SUMMARY

A case of severe erythema multiforme exudativum (Hebra) is presented, and the ætiology of the disease is discussed briefly.

In the pathogenesis of this condition an response to bacteria, bacterial products, drugs, and sources of protein probably plays an important

I wish to thank Prof. E. P. Sharpey-Schafer for to publish this case, and Dr. Russell Fraser for help manuscript.

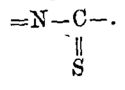
Preliminary Communication

TASTE SENSITIVITY TO PHENYLTHIOU IN GOITRE AND DIABETES

PHENYLTHIOUREA tastes bitter to some people not to others.[1] In European and American popula the distribution of taste thresholds has been found bimodal, about 30% of the individuals tested falling the relatively insensitive (non-taster) class. It is tho that non-tasters are homozygous for a single rece gene.[2] According to Harris and Kalmus,[3] tasters non-tasters with respect to phenylthiourea show same differential taste response to a large numbe other substances containing the grouping:



$$=\mathrm{N}-\underset{\underset{\mathrm{S}}{\|}}{\mathrm{C}}-.$$

Many of these substances are known to be goitrog and some probably occur naturally in common food

In view of these facts it seemed worth whil examine the reactions to phenylthiourea of pati suffering from different forms of thyroid disease. have studied 352 patients with thyroid disorder and controls we have data on 541 normal subjects. In vi of the findings of Terry and Segall[5] that the propor of non-tasters is higher among diabetics we have studied 103 diabetic patients.

The main findings are summarised in the accompany table. The patients with thyroid disorder were classi into two main groups: toxic diffuse goitre (prim thyrotoxicosis), and nodular goitre. In 71% of latter the nodular character of the goitre was by examination of the specimen obtained at operati 61% of the nodular goitres were non-toxic.

Group	Total no.	No. and % of non-tasters
rol subjects	541	169 (*31·2%*)
tic patients	103	31 (*30·1%*)
d diffuse goitre	218	67 (*30·7%*)
lar goitre	134	55 (*41·0%*)
Totals	996	322 (*32·3%*)

he taste sensitivity in all the controls, the diabetics, most of the thyroid patients was measured by the hod of Harris and Kalmus.[6] in which exact taste sholds are determined. Some of the thyroid patients) were classified according to their response to a le critical solution of phenylthiourea.

he proportion of non-tasters in the group of patients toxic diffuse goitre and in the group of diabetics es very well with the proportion found in the rols. There is, however, a somewhat higher incidence of non-tasters among the patients with nodular goitre: this is significantly different at the 5% probability level from the proportion found in the controls ($\chi^2=4{\cdot}65$ for one degree of freedom). There was a similar proportion of non-tasters among the cases of toxic and non-toxic nodular goitre.

The data suggest that non-tasters may be somewhat more susceptible to the development of nodular goitre than tasters, though the number of patients it has been possible to examine so far, and the level of significance in the differences observed, are hardly adequate for such a conclusion to be drawn firmly. The object of this note is to stimulate similar inquiries in other centres.

New Inventions

A SET OF CALLIPERS FOR ANATOMICAL MEASUREMENTS

HE callipers described here were designed and structed in the radiotherapy department of the al Northern Hospital, mainly to assist the radio-apist to plan treatment, but they should also be ul in gynæcology, obstetrics, and other branches of licine.

ig. 1 shows two pairs of callipers which are identical, ept in size; the larger pair reads from 0 to 60 cm. the smaller from 0 to 50 cm. Two sizes were structed because it is sometimes necessary to make of the greater depth between the tips and the pivot he larger pair. On the other hand, the smaller pair sometimes easier to manipulate. A scale of centi-res in 0·5 cm. stages is provided on three sides of one to enable a direct reading to be taken in any likely ition. The two arms, which are pivoted at the upper remity and may be locked with a thumbscrew, are nected by a link which slides an indicator along the le as the arms move and thus registers the distance ween the points. The callipers are operated by hold- the handle in the left hand and sliding the indicator h the right hand by the grips provided. As the arms n, the link retreats towards the pivot and allows the l depth of the callipers to be used for the greater measure-nts. The scales are not linear but are openly spaced the lower readings and close gradually towards the her readings. Thus all measurements may be made h about the same degree of accuracy. In other lipers the scale markings are often so small that low les are difficult to read.

ig. 2A shows a pair of callipers intended primarily locating the position of the cervix with reference to e skin surface, or for measurements from the rectum, but it also has other uses. There are two horizontal arms: one straight and fixed, and the other shaped and sliding on a vertical pillar above it. The fixed arm is of polished metal on which is engraved a scale of centimetres in 0·5 cm. stages. A small slide, which can be fixed with a set-screw, indicates the depth of insertion. Since this arm is inserted into the vagina it is made detachable for cleaning and sterilisation after use. The upper arm slides vertically along its supporting pillar, on both sides of which is a scale of centimetres reading from 0 to 23 cm. The instrument is held by the handle, and the fixed arm is inserted into the vagina until the extremity reaches the cervix. The upper arm is then lowered until its point touches the skin, when the vertical distance from the cervix to the skin can be read directly from the scale, which is full size. In a similar instrument, described by Jarvis,[1] the scale is considerably reduced and must therefore be less accurate, and the tip of the moving arm is not vertically above the tip of the straight vaginal rod except in one position.

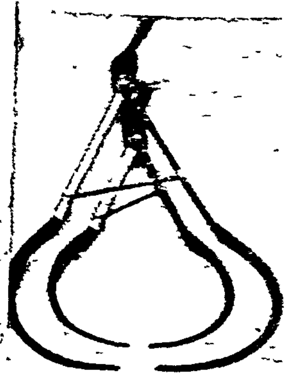

Fig. 1.

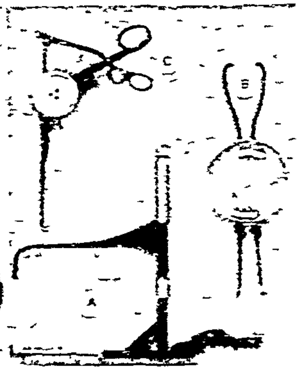

Fig. 2.

Fig. 2B shows a combination of inside and outside callipers designed for making transverse measurements in the mouth, though it has other purposes. This instrument is intended for smaller measurements than the three previous models, so the scale on the central dial gives a magnified reading (1·7/1 cm.). The range is 0–20 cm. for the outside callipers and 1·5–20 cm. for the inside callipers. The dial is rotated by a fine chain drive anchored to the two limbs of the callipers and passing round a central pulley. A spring-loaded pulley keeps the chain taut in all positions of the arms. The dial and mechanism are enclosed in a transparent case. The instrument can be operated with one hand.

Fig. 2C shows an instrument for making anterior-posterior measurements in the mouth. The callipers consist of two parallel members, one fixed and the other moving. The extremities have small extensions at right angles to the arms so that the operator can easily observe the position of the tips. The moving member slides along the underside of the fixed one and is operated by a scissors motion. A rack cut in the sliding member works a gear-wheel which rotates a dial bearing, on both sides, a scale with a magnified reading (2/1 cm.), the range being 0–10 cm. The scissors grip allows the instrument to be operated with one hand.

This set of instruments can be used to take all the body measurements for which callipers are normally required, and in each case the ease with which the scales can be read while in position on the patient has been the first consideration.

All the legs of the callipers except the vaginal rod shown in fig. 2A are made of 'Tufnol,' which is light and strong and can be sterilised in 'Dettol' without harm.

Reviews of Books

Modern Practice in Ophthalmology

H. B. STALLARD, M.B.E., M.A., M.D., F.R.C.S., surgeon, Moorfields, Westminster and Central Eye Hospital; eye surgeon, St. Bartholomew's Hospital, London. London: Butterworth. 1949. Pp. 525. 65*s*.

THIS is the work of 14 different authors, giving their views on modern ophthalmic practice for the information of the general practitioner. The routine groundwork has been well covered and the information is standard ophthalmic teaching. It seems doubtful how much the family doctor will want to know of optics and the theory of refraction, and a good deal of this section might have been omitted in favour of a longer discussion on contact lenses and an exact summing up, based on some hundreds of cases, of the extent to which patients who have bought these lenses have subsequently worn them.

Dr. S. P. Meadows's section on medical ophthalmology is outstanding for its lucidity and learning, while Mr. John Foster on methods of examination, and the editor himself on surgical topics, make excellent reading. In a new edition Mr. Bruce Hamilton might make it clear what anæsthetic he uses for probing the lacrimal passages in the adult; at present the reader is left to presume that cocaine drops are used, and these would certainly be inadequate. The writer on retinal detachment should warn the practitioner that his duty towards a patient with suspected or diagnosed retinal detachment is to send him to bed until a specialist's advice can be obtained. There are many good colour illustrations, but also some which are old and should be improved. The book contains a great deal of useful information and presents modern ophthalmology from many different aspects.

The New York Academy of Medicine

Its First Hundred Years. PHILIP VAN INGEN, M.D. New York: Columbia University Press. 1949. Pp. 543. 55*s*.

EVEN though, as Dr. Van Ingen explains, he was equipped with "a two-machine Soundscriber," which enabled him to dictate while the previous day's dictation was being typed, the task of compiling this history from at least 12,000 pages of minutes of meetings of the academy and of its committees—in the early years often in almost illegible handwriting—proved formidable. The result of his labours cannot fail to be interesting; yet in a way it is also disappointing. His book is not so much a history of the academy as a vast collection of material from which such a history might be written. To adhere to a strictly chronological sequence, from session to session and from president to president, makes for a disconnected story. For each session the list of appointments to office, of resignations, and of deaths must be given, the financial position and the work of the various committees reviewed, scientific communications appraised, new ventures and developments described, disputes and accusations put on record. A considered and continuous account of the steady rise in ethical standards would have been fascinating, for the academy was founded in an America which had not yet shed its roughness and rawness. The fellows first appointed seem to have regarded it mainly as an association likely to strengthen their hands in the bitter struggle for daily bread against charlatans of all sorts. Its committee on admissions seems never to have asked itself "Is there any reason why this man should be elected?" but always "Is there any reason why he should not be elected?" Collection of dues—the tax, as it was called—was a matter of great difficulty, and so many were in arrears that a professional collector had to be employed. Charges of advertising or of fee-splitting were brought even against men who were prominent in the affairs of the academy. As late as 1879 the president, Dr. Barker, was accused of falsely claiming to be a graduate of medicine of Paris, thus rendering himself liable to prosecution for perjury. The president's defence was that he had lost the diploma; but he called friends to witness that it had once been in his possession, and the committee of ethics unanimously voted that the charge was unsustained—even though the Faculty of Medicine of Paris stated that his name was not on their lists.

The change from all these unhappy beginnings to high position, secure and honoured, which the now holds is the fascinating theme of this book, though it is by the simultaneous consideration of aspects of development.

Diagnostic Tests for Infants and Children

H. BEHRENDT, M.D. New York and London: Publishers. 1949. Pp. 529. 57*s*.

Dr. Behrendt is to be congratulated on his industry in bringing together in one volume the for diagnosis of disease in infancy and childhood. book should interest the clinician who is anxious to his clinical findings by biochemical tests and to the way in which the various morbid processe produced. The material is comprehensive anc arranged and each test is dealt with under subhe —such as pædiatric considerations, procedure interpretation. In some sections the pædiatri siderations are very brief and might well be in in the interpretations, which are well done an the reader a good idea of the value of the tes the significance of departures from normal. The are described in detail; in some instances (in te the estimation of inorganic phosphorus for more than one method is given, but Dr. Behrend not state his own preferences. Besides tests f diagnosis of digestive, renal, hepatic, and en functions, there are chapters (some written by authors) on the inorganic constituents of the and on the tests used in the study of vitamin nu immunology, psychology, hearing, and sight. simple side-room tests are omitted. There is a v list of references at the end of each chapter, and th will be a useful addition to every pædiatric re library.

Year Book of Medicine, 1949 (Chicago: Y Publishers. London: H. K. Lewis. 1949. Pp. 831. 31s The editors, led by Dr. Paul B. Beeson, this year cove advances in the medical care of infections, the ch blood and blood-forming organs, and the kidney, th and blood-vessels, and the digestive system. The and value of volumes in this series are well known, one carries on a sound tradition.

May and Worth's Diseases of the Eye (London: Baillière, Tindall, and Cox. 1949. Pp. 548. —Ever since May and Worth first appeared in 190 been intended as a textbook for students and genera tioners. This aim has been maintained by Mr. Mon Hine, F.R.C.S., in producing the new edition, and he his job admirably. In a volume of handy size and ea type both student and practitioner will find the a any question in ophthalmic practice with which th be confronted; indeed as value for money it is har how this little volume could be bettered. It does no that some of the ophthalmic operations described h somewhat superseded, for the reader of this book will know nothing but the bare outlines of such procedu figures are good, though no. 100 shows a lacrima pointing in a strange direction if it is to pass d nasolacrimal duct.

Illustrations of Surgical Treatment, Instr and Appliances (3rd ed. Edinburgh: E. & S. Livi 1949. Pp. 391. 25s.).—After a short chapter on int infusion, Mr. Eric L. Farquharson, F.R.C.S., introd main feature of this book—ingenious methods of fractures, well illustrated. Recent methods have be porated, and the whole section is most comprehen useful. No less than 120 pages of illustrations of instruments follow. These may be of value to exa candidates (if they are still expected to name the instruments) but are of little use to the practical ma with fractures along the lines given in the main pa book. The main chapters are so delightful that mo would willingly sacrifice these illustrations in fa more text.

Messrs. H. K. Lewis are the English publi *Blakiston's New Gould Medical Dictionary* (see *Lancet*, p. 702.). The price is 45*s*. on ordinary paper and 55s. paper.

penicillin nonad tulle

In all branches of surgery, Penicillin Nonad Tulle has been welcomed as an effective bacteriostatic dressing for operation wounds, including those of eyes, ears and nose, and those of skin grafting.

This non-adherent, sterilized gauze dressing of wide mesh is impregnated with an emulsifying base containing 1,000 units of penicillin per gramme, equivalent to 160 units of penicillin per square inch of tulle.

Dressings of Penicillin Nonad Tulle are easily and painlessly removed without destroying the granulation and epithelial tissues in process of formation.

PENICILLIN NONAD TULLE

In tins, containing 10 pieces each 4" × 4", or a strip dressing 4" × 2 yds.

Menopausal Syndrome

Estigyn enables the symptoms of the menopause, due to decline in the œstrogen secretion of the ovary, to be effectively treated by specific replacement therapy.

Estigyn is a highly potent œstrogen derived from natural sources and is active orally. In addition it is non-toxic in therapeutic doses. The improvement in subjective symptoms and the restoration to normal outlook is, in many cases, gratifyingly rapid while at the same time the possible onset of pruritus vulvæ or kraurosis vulvæ is prevented.

Treatment of Pernicious Anæmia

IE general practitioner may well be confused by chopping and changing of opinion on the treat- t of pernicious anæmia. A bewildering array of arations faces him, many with names that bear relation to their use and give no indication of nature; and, to make things worse, he may on his desk literature from a pharmaceutical pressing the advantages of a preparation that he condemned in editorial columns.

hy do names for liver and similar preparations ernicious anæmia vary so aggravatingly? There is no sense in it. Insulin is always labelled sulin," followed by the brand or registered name s manufacturer, and carries a clear indication of strength of the contained solution: but liver acts are given such names as Campolon, Pare- ps, Plexan, Examen, Anahæmin, and Pernæmon e—names that in no way suggest that the first e are dilute whole-liver extracts; whereas the three are concentrated or highly refined. There exist one American brand which is informa- ly labelled: "X brand solution of liver extract. *.S.P.* units per c.c." In the U.S.A., moreover, rent liver extracts are available in strengths ing from about 3 to 15 *U.S.P.* units per ml.: the of the 15-unit solution needed for inducing ission in a relapsed case of pernicious anæmia is it 2 ml., and about 1 ml. fortnightly is enough maintenance. This seems simple enough, but rtunately these convincing-looking "units" are e arbitrary and their only value is to indicate the tion. If firm A makes one solution of 5 *U.S.P.* s per ml., and one of 15 units per ml., it is a onable assumption that if 6 ml. of the former s a good response, 2 ml. of the latter will do as l; but it certainly cannot be assumed that liver tact of 15 units per ml. made by firm B will duce an equally good response with a dose of d.—you have to try and see. The reasons for the ence of an internationally, or even nationally, ted unit of liver-extract activity have often been ussed, and the main one is that as test object no l substitute has yet been found for the pernicious- mia patient in relapse. Estimation of the content olic acid and of vitamin B_{12} has proved unreliable. l no other method, chemical or biological, has so stood up to proper tests. If such a test is found, will be a great help.

Meanwhile six groups of preparation * are offered the doctor:

A. *Liver extracts for intramuscular injection.*—These e relatively inexpensive: the dose for the patient in apse is 12–20 ml., and 2–6 ml. weekly suffices for aintenance. Examples: Campolon (Bayer), Hepastab oots), Hepolon (Allen & Hanburys), Parenamps (Paines d Byrne), Plexan (Glaxo).

B. *Concentrated or refined liver extracts for intramuscular injection.*—These are relatively expensive, but have the great advantage of small-volume doses: 4–6 ml. for the relapsed case, and 0·5–1·0 ml. weekly for maintenance. Examples: Anahæmin (B.D.H.), Examen (Glaxo), Hepastab Forte (Boots), Pernæmon Forte (Organon).

C. "*Proteolysed*" *liver preparations for oral use.*—These represent the most expensive way of treating pernicious anæmia (except for vitamin B_{12}), but they are useful for patients who dislike injections and cannot cope with preparations of group D. They are mostly used for maintenance, and DAVIDSON [1] thinks that they may be specially useful in those cases that are relatively resistant to treatment. The dose is $^1/_3$–1 oz. daily. Examples: Proteolysed liver *B.P.C.*, Hepamino (Evans), Proteolysed Liver (Paines and Byrne). The *B.P.* "Liquid extract of liver" is not a proteolysed preparation and is little used because it is unpleasant to take and has no special advantages.

D. *Desiccated-stomach preparations for oral use.*—These are somewhat expensive, but by some authorities (notably WILKINSON [2]) they have been particularly recommended for maintenance treatment of patients with neurological complications, and they have the advantage of providing a little addition to the protein ration. Dose $^1/_4$–1 oz. daily. Examples: Desiccated-stomach *B.P.C.*, Extomac (Bengers), Pepsac (Boots).

E. *Pure vitamin-B_{12} solution.*—This is the last-comer, and at the moment is very expensive. Vitamin B_{12} will definitely treat pernicious anæmia in relapse—but no better than the preparations in groups A and B. We are not yet certain about its value for maintenance.[3] It has, as yet, no place in the routine treatment of pernicious anæmia: but it may have, a year hence. Examples: Anacobin (B.D.H.), Cobione (Merck).

F. *Folic-acid preparations.*—These should *not* be used for the treatment of pernicious anæmia. The reason, which we have noticed before,[4] is that folic acid will not treat the neurological complications and may even accelerate their appearance; patients who have initially no disease of the central nervous system may develop it if kept on folic acid for long; a recent estimate [5] puts the risk at 80%. Administration of folic acid is the correct treatment for some megaloblastic anæmias—notably sprue—but not for pernicious anæmia. Examples: Folvite (Lederle), Plastules with Folic Acid (Wyeth).

The reason why folic acid is still used is, presumably, its convenience. When practitioners have little time they naturally prefer to prescribe a pill or capsule rather than give an intramuscular injection, and their patients also prefer it. But if the doctor cannot organise the time-consuming injections of groups A and B, he can use the preparations of groups C and D.

The position is then, that despite much agitation and promise of later advances, the treatment of pernicious anæmia, today, still rests on the proper use of liver and desiccated-stomach preparations.

Diagnosis and Treatment of Actinomycosis

THE striking success of the sulphonamides and antibiotics in actinomycosis has stimulated a new interest in this disease. WEED and his colleagues [6] at the Mayo Clinic, who have made a careful study of necropsy material and of current suspected cases, urge the importance of basing the diagnosis on a thorough bacteriological examination, which, when possible, should include identification of the causative actinomycete in culture. In their view errors are common when the diagnosis is based on clinical findings alone. Moreover, identification of the infecting species will guide the clinician in his choice of treatment.

6. Weed, L. A., Baggenstoss, A. H., Baugher, L. *Proc. Mayo Clin.* 1949, 24, 463.

About 90% of all cases of actinomycosis are caused by the anaerobic species *Actinomyces israeli* (syn. *A. bovis*), which, as LORD [7] showed in 1910 and many mycologists have since confirmed, is often present as a commensal in the healthy mouth, vegetating especially in tonsillar crypts, under the gum margins, and on carious teeth. In artificial culture the species is anaerobic or micro-aerophilic, of delicate habit, and incapable of producing spores or any resistant form. For this reason it cannot survive on natural substrata outside the animal body; so infection does not occur from external sources but is always "autogenous." The principal sites of the primary disease are the cervicofacial region, usually infected by direct extension from the mouth; the lungs, by aspiration infection; and the cæcal or appendicular region. Bacteriological examination is often necessary to establish the diagnosis of actinomycosis, but it is not always free from errors in interpretation, for the presence of actinomyces filaments or even "grains" in the sputum of a patient with a chronic pulmonary disorder does not necessarily indicate that the disease is pulmonary actinomycosis; the organism may have been vegetating in the mouth or even saprophytically in a bronchiectatic cavity. Last year KAY [8] isolated *A. israeli* from the sputum of 109 out of 240 hospital patients with chronic bronchopulmonary disorders, and from 65 of the 109 it was also isolated by bronchoscopic swabbing. Bronchiectasis with varying degrees of pneumonitis was present in 37 of the 65, in 8 others there was moderately severe chronic bronchitis, and the remaining 20 had aspiration pneumonia, lung abscess, or more extensive pulmonary suppuration. *A. israeli* is not uncommonly present, with other organisms, as a saprophyte in bronchiectatic and other chronic lung cavities, but it may play a more pathogenic rôle in some cases of chronic bronchitis, aspiration pneumonia, or local abscess, and these foci, from which more extensive disease may develop, should, when identified, be given prompt treatment. Material obtained by bronchoscopy, from draining sinuses, or from lung resection is far more satisfactory for diagnosis than sputum. SCHAIN and co-workers [9] isolated *A. israeli* from the bone-marrow and occasionally from the blood, cerebrospinal fluid, or liver tissue of four cases of Hodgkin's disease and three other conditions. None of the seven patients was suffering from actinomycosis, nor was *A. israeli* the cause of their clinical condition. In 8500 other specimens from various sources, including 1000 blood samples, they could not find this organism. It seems that, in the seven cases where it was found, *A. israeli*, probably from the mouth, had become a harmless parasite in the hyperplastic reticulo-endothelial tissue.

Aerobic actinomycetes belonging to the genus Nocardia are responsible for the remaining 10% of cases of actinomycosis, and the most important of these are the systemic infections, chiefly pulmonary, caused by the partly acid-fast *Nocardia asteroides* group. BENBOW and colleagues [10] referred to pulmonary and 2 peritoneal infections by this all of which were fatal, and KIRBY and MCNAU mentioned 32 cases, of which 28, all pulmonary tions, were fatal. Clinically, the pulmonary may resemble tuberculosis, but careful bacteriol examination, including inoculation into guinea should exclude tuberculous infection. *N. aste* is not sufficiently acid-fast to be detected by ordinary Ziehl-Neelsen staining method, but easily stained by Gram's method and is not diffic cultivate from morbid material.

The older forms of treatment of actinomycosis iodides, iodine, or thymol have been supersede the sulphonamides, penicillin, and streptomyci of which have been effective in particular cases general, *A. israeli* infections yield, at least tempor to treatment with the sulphonamides, of whic most useful seem to be sulphadiazine and 'Su triad'; but sulphonamide treatment must be prolo in some cases even for two years, to insure ag recurrence, for the early dramatic improvem often misleading. Penicillin is probably the effective agent in actinomycosis caused by *A. isr* but the initial dosage must be large enough to pr the development of penicillin-resistance in the par Streptomycin was used with apparent succes TORRENS and WOOD [13] and by PEMBERTON HUNTER,[14] in four cases of *A. israeli* infection, of which had previously been treated unsucces with sulphonamides and penicillin. There have few published reports on the treatment of *N. aste* infections with antibacterial drugs, but BE and colleagues,[10] among others, have found sulphonamides effective, and the Mayo Clinic wor point out that *N. asteroides* is sensitive to the sul amides but not to penicillin. In Paris, D'ESHOU and ZAFFRAN [15] report a case of pulmonary ac mycosis (*N. asteroides*) which recovered on strept cin after massive doses of penicillin had failed. writers emphasise the importance of surgical vention, when feasible, especially for the draina pus, without which chemotherapy may fail. R therapy, accessory chemotherapy, and the ge management of symptoms are important secon measures.

Does It Work?

IN 1947, at the request of the National Found for Infantile Paralysis, the therapeutic trials mittee of the American Medical Association fo a special subcommittee to investigate the val moist heat in poliomyelitis. In a preliminary rep this subcommittee has set out the principles t followed by those who undertake to test any therapeutic agent in poliomyelitis. The r illustrates how extraordinarily difficult and expe it may be to assess the value of treatment in

ase which. like poliomyelitis. has a complex ology, a variable course. and an uncertain termi- on. In planning clinical trials of a poliomyelitis edy many variables must be taken into account des the unpredictable course and outcome of the ase. These include differences in diagnostic criteria possible differences in the effects of various types he causative virus; the results of climate and graphical situation; the age-distribution of the ents; and the techniques used to measure the nt of paralysis, deformity, and disability caused he disease. To control these variables adequately subcommittee believes that at least 750. and erably 1500. poliomyelitis patients should be er observation for at least two years. This means the trial must be conducted on a regional or onal scale and that a large number of hospitals t collaborate in it. A hospital participating t agree to accept cases strictly in accordance predetermined diagnostic criteria, to classify n carefully according to the stage of the disease admission, to assign them to control and test ps in a completely random manner, to give tical physical and other treatment—apart from treatment to be studied—to each group, and to nge for the collection by experts of data on the ress and outcome of each case in a form which be analysed statistically.

hree main diagnostic criteria are suggested: acute onset of a febrile illness with headache. r, and a recognisable stiff neck. the fever in general to exceed 104°F and not to persist longer than days unless there are obvious complications to unt for it or bulbar palsy has developed: (2) if alysis is absent there should be, besides fever, a ed protein content and a cell-count of 50–100 c.mm. in the spinal fluid; and (3) the paralysis ent during the febrile period should be localised demonstrable—i.e., not merely a generalised scular weakness. With these criteria, and excluding ients seen later than 28 days from onset (the inning of fever), the patients should be classified three categories: (1) preparalytic cases seen ing the febrile illness: (2) paralytic cases seen ing the febrile state up to 7 days after onset; and paralytic cases seen 8–28 days from onset. For random assignment of patients to test and control ps the subcommittee has adapted a method ginally used in a British Empire Cancer Campaign estigation; this ensures that in every 20 consecu- e admissions 10 patients will be assigned to the group and 10 to the controls, and that one p can never exceed the other by more than patients. It is neither justifiable nor practicable. the subcommittee's view, to withold all treatment m controls. A basic treatment carefully designed avoid the use of any agent which would confuse augment the action of the treatment under trial st therefore be decided on and rigidly applied to test patients as well as controls. For the collection data on progress and outcome which can be mitted to statistical analysis, the subcommittee commends that every patient in the trial should examined and assessed by a team of experts who e prepared to make frequent visits to each hospital king part in the trial. This team should, they nsider, include an orthopædic surgeon, a specialist in physical medicine. a pædiatrician, and a neurologist. All its members should be clinically independent of the trial and familiar with the results of orthodox treatment. without, however, having any fixed ideas on or preferences for any particular form of therapy. They should not know at the time of examination whether a particular patient has been in the test or control group. The final interpretation of the data should be the joint work of the hospital clinicians. the team of experts. and a statistician.

Reports, all too frequent in the past, of "encouraging" results with a new treatment were often based on the hasty assessment of half a dozen patients and sometimes contributed more to "medical myth and mumpsimus" than to the science of medicine. The way of the assessor in a therapeutic trial is indeed hard and in most respects not immediately rewarding. Statisticians are never satisfied with small numbers and demand from those who undertake to collect data for them an impersonal attitude to patients and a mechanical kind of work which many doctors find insupportable over long periods. Yet the carefully controlled large-scale trial of a therapeutic innovation, tedious and expensive though it may be, seems the only satisfactory way of answering the question "Does it work?" In the long run the cost of such trials is probably more than offset by the saving they effect by preventing or ending the use of expensive treatments when something cheaper would be just as good.

Annotations.

HOSPITAL FINANCE

THE drawbacks in the present method of financing the hospital service, to which we drew attention last summer,[1] have lately been reviewed, from a regional angle, by the North West Metropolitan hospital board; and representations are being made to the Ministry along the lines of a report by the regional treasurer. This suggests that the existing methods of approving estimates submitted by management committees lead to: (1) overstatement of requirements, because each committee tends to provide for unforeseen contingencies: and (2) guidance or direction from the Ministry on matters of detail. Furthermore the time-table for submission of estimates, which is dictated by the Parliamentary time-table, gives regional boards insufficient time to examine the estimates as closely as they should; and indeed "these committees have not sufficient data on the current rate of spending to be of use to them in preparing their estimates for the board," and they have to proceed with these estimates at the same time as the previous year's accounts are being closed.

The suggested remedy is that management committees should submit forecasts of expenditure to the board, which would review these "on a broad basis" and pass them to the Ministry of Health in time for the Ministry to decide on the sum to be included in its estimate. Detailed estimates could then be prepared by management committees for submission to the board by, say, the middle of November, and the board would be allowed three months for their examination. This, says the report, would give time for any major alteration in the total requirements of the Ministry of Health for the hospital service to be adjusted in the Civil Estimates.

> "After Parliament has approved the estimates the amount allocated for the hospital service could be allocated by the Ministry over the regional boards and boards of governors, leaving the regional boards freedom in the utilising of their

---

[1] Leading article, *Lancet*, July 9, p. 61.

allocations in the best interests of their areas. Boards should also be allowed to provide in their estimates a contingency item to meet supplemental estimates which must occur in this service. Balances should be retained in the accounts of regional boards and would require review at the time of each budget. It may be argued that this is contrary to Governmental accountancy practice, but it should be remembered that the keeping of accounts by hospital authorities on an income and expenditure basis is also contrary to the practice in national finance."

Financial policy, it is admitted, should undoubtedly be a matter for the Ministry, but the need for instructions on detail is not apparent. "Regional freedom in finance within the limits of a broad Ministerial policy would obviate the need for the issue of instructions on comparatively minor matters."

In the field of capital finance the existing policy of allocating to regions an annual sum of which any part remaining unexpended at the end of the financial year is lost, encourages spending on works having a comparatively low priority; the boards should be allowed to carry forward unexpended capital allocations, and in this way essential major work could be undertaken with the knowledge that the necessary money will be there.

At the same meeting the board agreed to an interim scale of charges to medical and dental staff for board and lodging. This scale has been commended to management committees with a view to securing uniformity throughout the region; and later all four Metropolitan regions will try to agree on a uniform scale. Such a course would go far towards meeting the complaints of registrars who have found that between neighbouring hospitals the charges vary widely.[2]

PROGNOSIS IN CEREBRAL HÆMORRHAGE

WHEN a patient is examined shortly after a stroke it is usually difficult to assess either the immediate prognosis or the risk of further vascular accidents. Tennant and Harman[3] have tried to analyse factors which may influence the prognosis by studying 107 patients with cerebral vascular accidents admitted to the Wisconsin General Hospital. There were 5 cases of cerebral embolism, which are not considered further, 27 of cerebral thrombosis, and 75 of hæmorrhage. In the differential diagnosis of thrombosis and hæmorrhage the criteria suggested by Aring and Merritt[4] from a study of 245 fatal cases have been used, and though these are certainly not infallible they are a useful guide in differentiating the two conditions. The proportion of 75 cases of hæmorrhage to 27 of thrombosis is unusually high, probably because only the more serious cases were sent to hospital—22 of the 75 patients with hæmorrhage died but only 2 of the 27 with thrombosis.

Hæmorrhages from congenital aneurysms were excluded from the series, and only 12 of the patients considered had a hæmorrhage before the age of 40, the greatest number occurring during the sixth decade. The chance of a hæmorrhage proving fatal appeared to be greater if it occurred before 40 or after 60. In general, if the systolic blood-pressure was above 190 mm. and the diastolic above 140 mm. Hg, the risk of death seemed to be increased. The depth of coma did not appear to bear much relation to the outcome of the attack but the duration of coma was of considerable importance; none of the patients who recovered were in coma for longer than two hours, while in the 22 fatal cases coma always lasted for several hours. Another prognostic sign was the occurrence of abnormal respiratory rhythm, particularly Cheyne-Stokes respiration. All except 6 of the fatal cases had long periods of altered respiration, while only transitory abnormalities occurred in the patients who recovered. The series was scarcely large enough for estimation of the eventual outcome in patients survived the initial attack, but 10 had a second hæmorrhage, 4 a third, and 1 a fourth. The mo second attacks corresponded to that of the first.

Rose[5] studied the problem from a different ang estimating the time between the onset of an attack death in a series of 205 cases dying of cerebral h of Leeds General Infirmary. His series included 30 in hæmorrhage from intracranial aneurysms and no than 27 cases of apparent cerebral thrombosis in secondary hæmorrhage occurred about a week after initial attack, probably the result of alteration in nutrition of an arterial wall in relation to the ar softening; this group is of particular importance the use of anticoagulants is considered in the a cerebral thrombosis. No patient in this series wit primary hæmorrhage into the cerebral survived for longer than four days.

RALLY OF REGISTRARS

THE inaugural meeting of the registrars' group of British Medical Association was held in London Saturday, Nov. 26. Some months ago registrars up down the country, persuaded that in their difficult they must help themselves, began to band th together into regional groups; and from these lo bodies emerged a national committee which convinc the council of the B.M.A. that recognition should not withheld. Hitherto registrars from teaching hospita have tended to hold themselves apart from the movement; and at last Saturday's meeting the acrimonio debate on constitution, which occupied more th half the day, suggested that some now regret havi allowed their non-teaching colleagues to gain unquestion ascendancy. When the meeting turned to pol dissidence vanished; and the day ended with handso tributes to the antecedent organisation which, thou lacking any powerful backing, had already achiev notable results.

The new group is to press for representation on th various medical advisory committees; for the filling hospital establishments with the least possible dela and an assurance that no registrars in established pos will be dismissed until these establishments are defined for an undertaking that fully trained registrars unde notice of dismissal shall not be lost to the service unt establishments are known, and that at least two month notice of dismissal will be given; and for investigatio of methods of filtering off surplus registrars. A Ma chester delegate believed that only 1 in 5 of seni registrars would get a consultant post, and urged th the position of registrars should be clarified; for a present they had no idea what to do. He was alarme by the paucity of vacancies "with reasonable prospects in general practice, and reasoned that in any event man who had been doing specialist work for three four years would need reablement to fit him for gene practice. The meeting viewed with alarm the apparent uncontrolled growth in the number of registrar posts, an agreed that the establishment of consultants must b known before the desirable number of registrars coul be determined. Before the war, it was pointed out registrar appointments were largely confined to teachin hospitals. Now, however, such appointments had bee made to small and ill-equipped hospitals with no faciliti for training, while in the larger non-teaching hospital a consultant with 200 beds might have as many as nin registrars. Should there not, it was asked, be a exchange of registrars between the teaching and the non-teaching hospitals; for surely, now was the time to end the division between the two groups by aiming at a uniformly high standard. At present registrars were commonly doing the work of consultants; and aermore the fitness of some consultants to have strars was open to question.

he meeting also called for a clear expression of the ria for appointment to the various grades of registrar s. Quite junior posts were now being reserved for with higher qualifications and long experience who ld really be senior registrars or even consultants; this made the position of the young man in training difficult. The feeling seemed to be that appointts should be made by the regional board; but a ible modification suggested was that, while the strar should be in contract with the board, the ultant concerned should appoint him.

he insecurity of the registrar's tenure also engaged meeting's attention. Not only were many now er the shadow of dismissal at short notice but new ointments were being made for short terms; and an ance was cited where a senior registrar's post with ssured tenure of only six months had been advertised. speaker argued that registrars were all civil servants; he knew no other groups of civil servants approachmiddle life who were equally insecure.

he discussion of policy was notable for the restraint which registrars explained the grave straits in which y of them are placed. Flowing through the dission was the thought embodied in the first of the p's long-term aims—"that all registrar posts be gnised for training purposes for specialisation." he group can gain this end, it will have benefited not those it represents but the whole service.

PENICILLIN IN PERITONITIS

NE of the remarkable features of penicillin is that as maintained and in many respects even surpassed early promise. This is very different from the usual erience with a new drug or treatment which wins a h reputation at the outset. Moreover, penicillin's l of application is still widening. The early experintal work suggested that no benefit could be expected n penicillin in peritonitis of intestinal origin or ctions of the urinary tract because the infecting anisms were not susceptible, but later clinical reports[1] e shown that penicillin may after all play a useful t in the control of infection in prostatic surgery, there is experimental evidence that penicillin is ctive in peritonitis originating in the appendix.

othenberg and his fellow workers[2] conducted a ies of controlled experiments on dogs to compare effect of sulphonamides, streptomycin, and penicillin, administered in various ways, on the course and come of peritonitis produced by dividing the bloodsels of the appendix, ligaturing its base, and then shing it. All the control animals died, the average iod of survival being 39 hours. The commonest ecting organisms were *Bact. coli*, clostridia, *Strep. alis*, and *Staph. albus*, in that order of frequency. e first groups of treated animals were given sulphonides intravenously, intraperitoneally, or by both tes combined. Not one dog's life was saved by these gs, though the period of survival was doubled when combined route was used. Streptomycin given ramuscularly saved the life of one out of fifteen dogs, e survival period of the remainder being about the me as in the sulphonamide group. Ten dogs received eptomycin intraperitoneally and none of them was ved. In six of these dogs as much as 4 g. of streptoycin was instilled at a time and they all died within minutes of the first or second instillation, from resratory failure due to the toxic effect of the drug, the lood-level of which rose to 160 units per ml. Penicillin lone was effective. Given intramuscularly in large doses alf a million units daily for 6 days) it saved four out of five dogs, and the fifth survived for a week before dying of fulminating peritonitis reactivated by exploratory laparotomy. Smaller doses of ordinary commercial penicillin were a good deal less effective, but 100,000 units daily of penicillin containing 15–25% of penicillin X saved nine out of ten dogs. Given intraperitoneally even penicillin X was of little use.

These encouraging experimental results support a current clinical impression that penicillin is improving the outlook in peritonitis of appendiceal origin, but they are not easy to explain on the basis of bacteriology. In vitro penicillin is not usually potent against *Bact. coli* and *Strep. fæcalis*, for instance, two of the principal agents in enterogenic peritonitis, whereas *Bact. coli* is susceptible to streptomycin. Yet in these experiments penicillin succeeded and streptomycin failed. On the other hand, lately Yeager and his fellow workers[3] have reported that streptomycin increases the survival-rate in experimental appendiceal peritonitis in dogs from 20 to 60%, though they gave a smaller dose and started it later than Rothenberg et al. They also tried 'Aureomycin' and found it still more effective.

THE SCHOOL HEALTH SERVICE

SCHOOL medical inspection began with the Education Act of 1907, since when the scope of the school medical service has steadily expanded. The nurse joined the doctor in 1908; power to pay for certain forms of treatment (eyes, teeth, minor ailments, and tonsils and adenoids) was given to education authorities in 1918; and in recent years specialist clinics have been developed. In 1944 education authorities were made responsible for arranging the provision of comprehensive free treatment for all school-children and for the aftercare of children leaving hospital.

Sir Wilson Jameson's latest report on the Health of the School Child[4] testifies to the success of the work of the past forty years. Those who read Charles Booth[5] may recall his description of the children just before the school medical service began: "Puny, pale-faced, scantily clad, and badly shod, these small and feeble folk may be found sitting limp and still on the school benches in all the poor parts of London." Happily, times have changed; and it is a remarkable testimony to progress that Sir Wilson Jameson's report deals mainly "with provisions for raising the general level of child health rather than the detection and treatment of actual defects or disabilities of body or mind." The problems facing the school service are gradually changing. For example, now that nutritional disease detectable by clinical examination is disappearing how are we to assess nutritional state without using the costly procedures of the laboratory? No doubt wisely, the doctor is now asked to comment under the heading of "general condition" rather than "nutrition." In 1947 the number of categories was reduced from four to three (A=good, B=fair, and C=poor), and "what is wanted is the examining medical officer's general impression of the child's physical fitness." Secondly, how can the school service be brought into closer touch with the pædiatric world? Mention is made of the arrangements in the West Riding of Yorkshire whereby in 1947 and 1948 two whole-time pædiatricians were appointed to the school service with the title of child health officer, working both on the curative and preventive sides. This scheme, according to the county school medical officer, Dr. Fraser Brockington, "ensures that all the medical staff engaged on preventive children's work have a specialist as their professional head, to whom they can look for advice and guidance and who sustains their allocations in the best interests of their areas. Boards should also be allowed to provide in their estimates a contingency item to meet supplemental estimates which must occur in this service. Balances should be retained in the accounts of regional boards and would require review at the time of each budget. It may be argued that this is contrary to Governmental accountancy practice, but it should be remembered that the keeping of accounts by hospital authorities on an income and expenditure basis is also contrary to the practice in national finance."

Financial policy, it is admitted, should undoubtedly be a matter for the Ministry, but the need for instructions on detail is not apparent. "Regional freedom in finance within the limits of a broad Ministerial policy would obviate the need for the issue of instructions on comparatively minor matters."

In the field of capital finance the existing policy of allocating to regions an annual sum of which any part remaining unexpended at the end of the financial year is lost, encourages spending on works having a comparatively low priority; the boards should be allowed to carry forward unexpended capital allocations, and in this way essential major work could be undertaken with the knowledge that the necessary money will be there.

At the same meeting the board agreed to an interim scale of charges to medical and dental staff for board and lodging. This scale has been commended to management committees with a view to securing uniformity throughout the region; and later all four Metropolitan regions will try to agree on a uniform scale. Such a course would go far towards meeting the complaints of registrars who have found that between neighbouring hospitals the charges vary widely.[2]

PROGNOSIS IN CEREBRAL HÆMORRHAGE

When a patient is examined shortly after a stroke it is usually difficult to assess either the immediate prognosis or the risk of further vascular accidents. Tennant and Harman[3] have tried to analyse factors which may influence the prognosis by studying 107 patients with cerebral vascular accidents admitted to the Wisconsin General Hospital. There were 5 cases of cerebral embolism, which are not considered further, 27 of cerebral thrombosis, and 75 of hæmorrhage. In the differential diagnosis of thrombosis and hæmorrhage the criteria suggested by Aring and Merritt[4] from a study of 245 fatal cases have been used, and though these are certainly not infallible they are a useful guide in differentiating the two conditions. The proportion of 75 cases of hæmorrhage to 27 of thrombosis is unusually high, probably because only the more serious cases were sent to hospital—22 of the 75 patients with hæmorrhage died but only 2 of the 27 with thrombosis.

Hæmorrhages from congenital aneurysms were excluded from the series, and only 12 of the patients considered had a hæmorrhage before the age of 40, the greatest number occurring during the sixth decade. The chance of a hæmorrhage proving fatal appeared to be greater if it occurred before 40 or after 60. In general, if the systolic blood-pressure was above 190 mm. and the diastolic above 140 mm. Hg, the risk of death seemed to be increased. The depth of coma did not appear to bear much relation to the outcome of the attack but the duration of coma was of considerable importance; none of the patients who recovered were in coma for longer than two hours, while in the 22 fatal cases coma always lasted for several hours. Another prognostic sign was the occurrence of abnormal respiratory rhythm, particularly Cheyne-Stokes respiration. All except 6 of the fatal cases had long periods of altered respiration, while only transitory abnormalities occurred in the patients who recovered. The series was scarcely large enough for
estimation of the eventual outcome in patient
survived the initial attack, but 10 had a second
hæmorrhage, 4 a third, and 1 a fourth. The mort
second attacks corresponded to that of the first.

Rose[5] studied the problem from a different a
estimating the time between the onset of an atta
death in a series of 205 cases dying of cerebral hæm
of Leeds General Infirmary. His series included 3
in hæmorrhage from intracranial aneurysms and
than 27 cases of apparent cerebral thrombosis in
secondary hæmorrhage occurred about a week af
initial attack, probably the result of alteration
nutrition of an arterial wall in relation to the
softening; this group is of particular importance
the use of anticoagulants is considered in the pres
a cerebral thrombosis. No patient in this series
primary hæmorrhage into the cerebral hemis
survived for longer than four days.

RALLY OF REGISTRARS

THE AGED SICK

REVIEW OF 399 PATIENTS IN CHRONIC WARDS

J. M. GREENWOOD
M.D. Manc., D.P.H.
MEDICAL SUPERINTENDENT, WITHINGTON HOSPITAL,
MANCHESTER

or long ago Prof. A. P. Thomson[1] published a table survey of the type of patient treated in a large ningham hospital for the chronic sick. The survey have made at the Withington Hospital, Manchester, iot strictly comparable, because this is a general ital and most of the patients were admitted to the nic wards from the adjacent acute wards. The few ents who were admitted directly to the chronic ds were transferred to the acute wards if their lition required it, and in any case had access to full ay, pathology, and physiotherapy services.

this survey the patient's chance of rehabilitation been considered more particularly than in the ningham survey. Generally speaking, the longer the ent has been bedfast the less are his chances of very; and the best hope of recovery lies with those itted direct to a geriatric unit. But in practice y patients who have long been bedfast can be efited in health, and some can even recover the use heir legs. It is thus important that we should conr the treatment of the many thousands now in ital who were admitted before this new concept of care of the aged was developed.

he 399 patients reviewed here were housed in what formerly an annexe (belonging to the local authority) he general hospital; they are now the responsibility he hospital authorities. They had all been investigated, relegated to the chronic wards as incurable and ding nursing care only. When an active treatment was established in the hospital, it soon became lent that the bedfast hemiplegic patient could be le to walk out of hospital, that the bedfast doubly ntinent patient could be made continent and able eave his bed, that parkinsonism could be improved, t the patient with contracted legs could have his es straightened and learn to walk again, and that bedfast patient with nothing wrong except his age ld be restored to a different type of life. With this wledge and new outlook the rest of the patients in chronic wards were examined with a view to finding ich of them could be treated.

TABLE I

Patients	Manchester	Birmingham
.. ..	135 men 264 women	Men and women about equal in number
r sixty	85% of men 87% of women	92% of men 95% of women
lent more than year	90% of men 89% of women	62% of men 71% of women
nt more than ree years	51% of men 50% of women	26% of men 28% of women
lent more than ve years	26% of men 34% of women	.. ..

The summary of cases (table I) shows the difference tween the type of patient in the Manchester hospital d those in the Birmingham survey.

It should be borne in mind that most of the patients Birmingham were acutely ill on admission, while the anchester patients had been screened by admission to the acute wards before they were sent to the long-stay annexe.

NURSING NEEDS

On reviewing the 399 patients it was found that 25% of men and 31% of women were incontinent (compared with 25% of men and 44% of women in Birmingham). Though the proportion of incontinent patients was reasonably similar in the two sexes, as was also the proportion of those able to sit up, the proportions needing bed *attention differed considerably, being 38% of men and* 51% of women. In the same way, 24% of the men were able to get to the water-closet but only 9% of the women. It seems that men make their way to the toilet, without troubling the nurses, for as long as they can, whereas women are treated as bed cases because it is easier for the nurse to bring a bedpan than to help the patient to the toilet.

PHYSICAL STATE

The patients had all been investigated before, and their record-sheets showed a diagnosis; but sometimes the original disease had been overlaid by another condition: thus rheumatoid arthritis might have ceased to be active, and the patient might now be suffering from the disability of contracted knees. The diagnosis of senility was made as a rule when the patient showed general deterioration, not when there was deterioration of one system.

TABLE II

Diagnosis	Number			Suitable for treatment		
	M	F	Total	M	F	Total
Senility	38	75	113	6	14	20
Cerebral thrombosis	18	35	53	4	24	28
Cerebral arteriosclerosis ..	2	0	2	0	0	0
Myocarditis	7	20	27	4	9	13
Hypertension	10	12	22	2	6	8
Chronic bronchitis	16	11	27	7	10	17
Arthritis	5	33	38	5	26	31
Disseminated sclerosis ..	3	3	6	1	2	3
C.N.S. lesions (mixed) ..	5	4	9	3	2	5
Post encephalitis lethargica ..	8	14	22	8	14	22
Parkinsonism	2	9	11	2	9	11
Accidents (after-effects) ..	2	9	11	2	6	8
Operations (after-effects) ..	5	0	5	3	0	3
Carcinoma	2	13	15	0	5	5
Pernicious anæmia	2	3	5	2	3	5
Tuberculosis	3	1	4	3	1	4
Skin conditions	4	7	11	3	7	10
Others	3	15	18	2	10	12
Totals	135	264	399	57	148	205

M = males. F = females.

In judging the suitability of patients for treatment (table II) the criterion was of course the likelihood of benefit. The amount of benefit to be expected varied; some who were bedfast could probably be improved enough to walk out; others who were bedfast and had to be fed by the nurses might improve enough to feed themselves. Incontinent patients were not included in the group regarded as suitable for treatment, although many such patients can, in fact, be made continent. Assessment must always depend on a personal factor; and probably those admitted to the treatment group who would not improve are balanced by those who might have benefited but were rejected. If the survey had been made before the acute geriatric unit was established the proportion capable of recovery would have been put much lower; but once the possibilities had been recognised it was evident that some 42% of the men and 56% of the women could be improved by active treatment. A few recent cases illustrate how much recovery can be achieved in even the most unlikely subjects.

Mrs. A., aged 64, suffering from a hemiplegia with aphasia, was admitted to the geriatric unit 9 months after the stroke, having received attention in a general hospital. She was bedfast and incontinent, with a contracted right arm but interest and knowledge at a high level." Thirdly, there is the continuing problem of handicapped children. The report makes it clear that the accommodation for epileptics, which has altered little for fifty years, needs to be extended; likewise the spastic child and the partially sighted receive close attention. Besides much else that is of interest and importance, the report discusses physical education, the school dental service, and hospital schools. It emphasises the value of good records of the child's health at school.

LAMBL'S EXCRESCENCES ON THE MITRAL VALVE

ABNORMAL projections from the smooth surface of the cardiac valves are amongst the commonest manifestations of rheumatic or bacterial endocarditis. Attention was first drawn to similar lesions of less serious significance by Lambl,[1] who described small filiform processes on the ventricular surface of the aortic cusps. For many years these curious fibrous tags were thought to occur almost exclusively on the aortic valve, but in 1928 Grant, Wood, and Jones[2] reported their presence on the mitral valve in 70% of 40 normal hearts.

Magarey,[3] who has lately published a detailed study of the so-called Lambl's excrescences of the mitral valve, finds them remarkably common—they were present in 85% of 250 valves examined. The incidence rose from 0% in 22 cases under one year of age, to 100% in 75 cases over the age of 60. They may be single but usually are multiple, often exceeding twenty per valve. They vary in length up to 5–10 mm., and are filiform in shape but sometimes have a bulbous free extremity. Histologically they consist of a core of moderately cellular connective tissue covered by a single layer of endothelium. They are non-vascular but often contain deeply staining elastic fibres, which may be coiled in bizarre fashion. The pathogenesis of these processes, according to Magarey, is by organisation of fibrin deposits. Such deposits were observed by him in 7% of the valves studied, and in several cases partial organisation had already taken place. Since the fibrin is usually deposited in plaque-like fashion, the formation of a filiform process would result from its partial detachment before organisation. Günzel[4] offers an alternative explanation. He suggests that the constant flexing and extending of the valve cusps lead to a surface-fraying of the subendothelial connective tissue. Three observations by Magarey tend to support Günzel's view. Firstly, the absence of blood-vessels from the excrescences does not support an origin from organised fibrin. Secondly, elastic fibres are usually absent from organised fibrin—as for example, in the fibrous adhesions resulting from fibrinous pericarditis. On the other hand, a well-defined zone of elastic tissue is present in the subendothelium on the auricular surface of the mitral valve and would readily account for the presence of elastic fibres in tags arising by fraying. Thirdly, the only easy explanation of the bizarre coiled shapes assumed by the elastic fibres in the excrescences is that they result from sudden rupture of these fibres, such as would be expected through fraying from the surface. Whilst some filiform excrescences may arise by organisation of fibrin deposits, in most cases mechanical disruption would appear to be responsible; and their more frequent presence on thickened, and presumably less flexible, cusps supports this view. Moreover, the quite common association of these bodies with fibrin deposits upon the affected valve-cusps may well be a result, rather than a cause, of their presence, since any unevenness of the endothelial lining of the vessels is known to predispose to fibrin and platelet deposition. The organisation of such deposits will lead to thickening of the valve with gradual submersion of the filiform processes, as was observed by Magarey in several of his cases. The gradual thickening of valves commonly associated with increasing age therefore be due to a combination of wear-and fraying with the organisation of fibrin, whose depos is thus favoured. Changes of the same order take in the arterial system, if, as Professor Duguid[5] suggested, the intimal thickening of atheroscle is traceable to thrombosis.

IMPOTENCE

PROBABLY less than 10% of cases of impotence are to organic causes; but these causes are neverth very numerous, as Dr. S. Leonard Simpson was ab show in opening a discussion by the Medical Societ London last Monday. One of the causes that is ap be forgotten is diabetes, possibly because—as Dr. Sim observed—diabetics seldom volunteer this symptom. these patients, said Dr. W. G. Oakley, impotence arise in two ways: first, when they come under treatm and as soon as the diabetic state is stabilised the impot disappears; and secondly during the course of the di even when stabilisation is complete. In the latter g libido is not lost, testicular biopsies are normal. and sperms also are normal though the count may be slig reduced; yet the symptom proves intractable to tr ment. The cause, Dr. Oakley thinks, may possibly a neurovascular defect, or else endarteritis in the ves concerned in erection (and Mr. S. M. Cohen later sho that peripheral vascular disease is an important ca of impotence); but Dr. Simpson believes that someti the origin may be functional.

As to the undoubtedly functional cases, Dr. E. Strauss claimed that the commonest cause is anxie conscious or unconscious, primary or secondary. Strauss emphasised that sexual vigour is largely gene cally determined; and a "virile" physique is necessarily accompanied by great sexual vigour. W he terms "psychosexual impotence" may arise in number of different ways: (1) as "honeymoon" imp tence, which derives from ignorance, nervousness, a weariness, and may persist through memory of init ineptitude; (2) from masturbation anxiety, where t man is the subject of symbolic castration; (3) fro perverse components such as a sadomasochistic impul or homosexuality; (4) from unresolved incestuo attachments ("not a Freudian whimsy"); (5) fro unconscious fear of aggression; (6) through psycho-sexu immaturity (where the wife is commonly a "nice woman who is loved and respected, and only a "fast" woman i thought to have any interest in sexuality); (7) as relativ impotence, where the man is unable to achieve coitu with one particular woman, usually his wife; (8) a "soldier's impotence," where a brief courtship an honeymoon are followed by protracted separation i which the man may build up a fantasy picture of his wife or come to prefer sociality to sexuality, or becom sexually promiscuous and then prove impotent whe tenderness is demanded; (9) in association with a depre sive syndrome; (10) as an inability to ejaculate (usually associated with a narcissistic temperament; (11) owing to fatigue; and (12) owing to boredom, through rigid regard for convention. This list was supplemented by Dr. Henry Wilson, who suggested that sexual impotence i commonly one manifestation of a sense of general impotence in every field.

The meeting touched little on the question of treatment. This, according to Dr. Strauss, may be very easy or very difficult; and he conceded that there is substance t the argument of Dr. A. P. Cawadias that a holistic and humanistic approach may prove as profitable as the analytical. Mr. Kenneth Walker urged that before treatment is started the wife should be seen. Often she can throw light on the cause; and sometimes she i the cause.

5. Duguid, J. B. Lancet, Nov. 19, p. 925.

lliot Gorst, K.C., instructed by Sir Robert Gower, r, appeared for the practitioner.

ing the case, Mr. Taylor explained that the majority complaints arose from the association of Dr. Lyburn e Lyburn Clinic.

J. C. Hall gave evidence of replying to the following isement in the *Daily Telegraph* :

LYBURN CLINIC Tunbridge Wells. Tel. 1706. Fully d with X rays, laboratory, physiotherapy, &c., for the l and treatment of chronic cases.

ly he received a letter from Dr. Lyburn enclosing as described as a case-book, on the cover of which were l the title, address, and telephone number of the nd Dr. Lyburn's name and professional qualifications. ply stated that an inclusive charge of 16 gns. for a was made, and for an overhaul which only took a charge of 10 gns.

H. E. J. Martin, advertising clerk, *Kent and Sussex* , told of the handing in by another person of an sement headed : "Here it is! Dr. E. F. St. John presents his Fancy Dress Dance and Carnival. . . ." ; another saying : "Dr. 2108 will speak on the National Act." The accounts were sent to Dr. Lyburn and he believed the cheque was signed "Sands."

. H. Deag, deputy manager, Tunbridge Wells publicity nent, gave evidence on the notices about "Dr. Lyburn's ial Medical Gymnasium" in *What's On in Royal dge Wells.* On the first two occasions on which the announcements appeared, Mr. Deag recollected urn giving verbal instructions for them to be inserted ; not remember who came on the third occasion. He that for many years Dr. Lyburn had been carrying on ive political campaign in the division. Since the lings had been taken the institution had been called announcement "The Tunbridge Wells Remedial sium," not "Dr. Lyburn's."

F. Moon, in evidence, said that on the gate of what erstood was Dr. Lyburn's house appeared the number " painted on in the same manner as a street number. xamined, he said he was not sure whether the number as preceded by the word "Ex."

yburn told the council from the witness-box how he mpaigned for diagnostic clinics. During a serious he had made a solemn vow that if he recovered he would his life and all he had to getting diagnostic clinics people of this country and America. When he got organised a clinic at Hastings similar to the one at lge Wells, except that it was bigger. "I paid for ing myself," he said.

939 he had joined the Labour Party. Before he went our in Wales he consulted the Registrar as to what d say ; he was told that it would be necessary for a ry complainant to bring an action against him for sing. Dr. Lyburn also stated that he had written a *he Fighting Irish Doctor*, and articles in newspapers. fought elections in the Tunbridge Wells district and stood there as the only independent medical candidate country, demanding diagnostic clinics.

clinic at Tunbridge Wells was equipped at his own —there was about £10,000 worth of equipment in it. 1200 complete overhauls a year were done. Expenses out £4000 a year, and so far it had never made a profit. ught it his duty to go into the National Health and see if it would work, so he enrolled as a general oner. He limited his patients to 500. If he had he could have had many more. He had put his al Health Service number on his gate for political es—"a number I was, not a person." He had now d, "because my case-records, and the story I may tell will indeed shake many human beings because overloading of our hospitals, which are doing wonderful and the strangling of the general practitioner without ay."

dvertised in the *Daily Telegraph* because he felt that n open advertisement in a national paper would give a of getting diagnostic clinics. The paper cut out the : "Bevan ought to provide them," which he included. o submitted a similar advertisement to the *British l Journal.* The accounts for the advertisements in *ent and Sussex Courier* might have been sent to him. He referred them to the appropriate authorities, and they were paid for by the treasurer of the clinic. In cross-examination, Dr. Lyburn said the club accounts were separate from his own. His own name had been used in the title of the club inadvertently. Directly he got the letter from the council the title was changed.

Miss Lilian Sylvia Edwards gave evidence that she was treasurer of the Tunbridge Wells Physical Training Club. This had been called the Lyburn Physical Training Club originally at her suggestion. She said the account stood at £3 credit. Dr. Lyburn had never received any of the proceeds.

Mr. Gorst, in his closing speech, submitted that what Dr. Lyburn had done was not infamous conduct. What he did, and what he always had in mind to do, was to foster and illustrate the idea that diagnostic clinics were a necessity. "He has not sought in any way to act detrimentally to other practitioners." Dr. Lyburn had not sought patients.

Mr. Taylor submitted that Dr. Lyburn was not entitled to do what he had done because he was activated by political motives, and asked whether it was conceivable that the advertisement in the *Daily Telegraph*, if it were an attempt at political propaganda, would have been inserted in that form ?

At the conclusion of these speeches, the Legal Assessor said it was manifest that Dr. Lyburn had been advertised. According to the letter of the charge, he was charged with advertising for the purpose of procuring patients and/or promoting his own professional advantage. "I think the council understand that you, Mr. Gorst, say that although he has been advertising, he has not been advertising for that purpose. Mr. Taylor invites the council to conclude that he has been advertising for that purpose, among other purposes." Supposing the council formed the view that the main purpose of the advertisement was to assist Dr. Lyburn to win a seat in Parliament at the next election, did Mr. Taylor say it was an offence against the Warning Notice, and did Mr. Gorst say that it was something which it was legitimate for a doctor to do ?"

Mr. Gorst : "I do. I say that the mind which goes behind the act is the dominating consideration."

Mr. Taylor thought it could not possibly be conceived as furthering Dr. Lyburn's candidature ; but if so it was still improper and within the confines of the Warning Notice to advertise in this particular form, which, in his submission, inevitably meant the promotion of Dr. Lyburn's own professional advantage.

The Legal Assessor : In other words, whatever his motives he must be deemed to foresee the natural consequences of his act ?—Mr. Taylor : Yes.

After a long retirement, the President announced that the council had found the facts alleged against Dr. Lyburn proved to their satisfaction in five of the charges.

Addressing Dr. Lyburn the President continued : "These facts bring you within the terms of that part of the Warning Notice which expressly states that advertising by a practitioner is, in the opinion of the council, contrary to the public interest and discreditable to the profession of medicine, and that any practitioner who resorts to any such practice renders himself liable on proof of the facts to have his name erased from the Register. Even if your attention has not been particularly drawn to the council's advice already, it should have been obvious to you that the kind of advertisement to which you have lent yourself cuts at the root of decent relationships between professional colleagues. You have told the council about your motives in committing your indiscretions and you have sought to argue that you may do with impunity as a politician that which you are forbidden to do as a medical practitioner. The council holds any such distinction to be logically and practically untenable. The council, however, feels itself justified in postponing judgment with the object of allowing you an opportunity to consider in the light of these proceedings and in terms of this decision what course you will take in the future. The council thinks that a period of six months will give you ample time to make up your mind on this point. You will therefore be summoned to appear before the council at the next session in May, 1950, and before that session you will be expected to furnish names of your professional colleagues and other persons who may feel satisfied with movement in her right leg. After rehabilitation this lady walked out of the hospital unaided, perfectly able to control her bladder and starting to talk again. Although her social circumstances had been investigated fully, she relapsed after returning to her daughter's home, and was readmitted with incontinence. A few days after her readmission to the geriatric unit she made a complete recovery again. She is now talking much more, having continued with speech-training. She is suitable for a long-stay annexe.

Mrs. B., aged 72, admitted to the geriatric unit as a bed patient, having been confined to bed for almost 3 years after a fracture of a right femur. She was also suffering from myxœdema, which had not been noticed. This lady is now walking in the grounds unaided and is awaiting admission to a hostel.

Mrs. C., aged 79, admitted for treatment, having been in bed for 2 years with contracted knees and rheumatoid arthritis of other joints. She is now being re-educated in walking and can, in fact, walk a little. It is hoped to discharge her to her home.

Mrs. D., aged 75, has been in bed for many years, complaining chiefly of pain in her back. Nothing abnormal was found and she was got out of bed. She is now fully dressed and up all day, and awaiting transfer to a long-stay annexe, since her home circumstances are not good.

Mrs. E., aged 73, was taken over from a chronic department, having been in bed for at least 18 months. She was doubly incontinent and mentally confused; the nursing staff thought there was nothing to be done. Within a period of 5 weeks this patient was up and dressed, able to walk short distances, had not soiled her bed for some time, and was mentally improved.

Mrs. F., aged 71, suffering from parkinsonism, had been bedfast and unable to turn over in bed or feed herself for many years. She is now able to turn over in bed and feed herself, and her tremor is much reduced.

CONCLUSION

The aged sick are only too often described as living a vegetable life in institutions. By adequate medical care we can hope to restore them to activity; moreover we can save hospital beds and nurses for those whose need is greater. One great difficulty in treating these patients is to find suitable quarters for them when they no longer need continuous medical and nursing care. This factor alone keeps many long-stay beds blocked. Since prevention is better than cure, I suggest that for proper medical care of the aged we need:

1. Active geriatric units attached to general hospitals, with additional accommodation for long-stay patients.
2. Outpatient units, providing treatment for the patient before he needs admission to hospital and able to follow him up after discharge from hospital and supervise his treatment.
3. Domiciliary teams, able to see the patient in his home and bring hospital services to him there. In some cases this care would make admission to hospital unnecessary.

GENERAL MEDICAL COUNCIL

SESSION NOV. 22–24

As recorded last week, Prof. David Campbell took the chair on his election as president in succession to the late Sir Herbert Eason.

Disciplinary Cases

Robert Hope Robertson, registered as of South View, Eldwick, Bingley, Yorks, M.B. Edin. (1927), appeared on a charge of having enabled Jules Samuels, of Weteringschans 73, Amsterdam, an unregistered person, to give advice and treat Miss Clara Louise Bruce, and of having allowed Francis Percival de Caux, an unregistered and unqualified person, to attend and treat Miss Bruce, without having made proper inquiries in either case. The complainant was Miss Bruce.

Mr. Gerald Howard, counsel, explained that Dr. Samuels practised medicine in the Netherlands; he had a medical degree in Holland and a degree which enabled him to practise in Germany, but he was an unregistered practitioner so as this country was concerned. In the second paragraph section 2 of the warning notice relating to unqualified a and covering, the words "*giving of advice*" did not app but the preamble made clear that the instances given in notice "do not constitute, and are not intended to constit a complete list of the offences which may be punishable erasure." The charge was worded to enable the council, i found the facts proved, to decide whether a practitioner enabled an unregistered person to give advice rend himself liable to have his name erased from the Register.

de Caux had been a registered practitioner but had had name erased from the Register following a conviction abortion and had had his qualifications removed by appropriate bodies. Mr. Howard said he could not reco another case where the unregistered person had in one insta been a foreign qualified person and in the other had previously a registered person.

Miss Bruce, in evidence, said she had developed a swellin the breast. On the advice of her doctor, she went to the Eliza Garrett Anderson Hospital, where she was advised to hav operation. She did not have the operation. Her brother thou would be a good thing for her to see a Dr. Parsons, but they f he had gone away, so she saw Dr. Robertson, who examine and showed her a book with pictures of a woman who had ca showing her condition before and after treatment. She a Dr. Robertson if this could happen to her, and he said: "If i a sister of mine, this is the treatment she should have." She electrical and sunlight treatment three times a week, and Dr. Robertson asked her if she would go to Amsterdam t Dr. Samuels.

Miss Bruce said she was examined in Dr. Robertson's pre by de Caux, who said he had studied under Dr. Samuels when Dr. Robertson was ill she was treated by de Caux. Wh was treating her, she went with him to Amsterdam, wher was examined by Dr. Samuels. In answer to Sir Sydney, S witness said Dr. Robertson had nothing to do with her vi Amsterdam.

Mrs. Maud Davis said that when Dr. Robertson came to se sister (Miss Bruce) he told witness: "Before I can treat sister I must be paid 50 guineas." Mrs. Davies said they woul the money, but when he added that the treatments would guinea a time she knew they could not pay that. Dr. Rob said that as they were paying 50 guineas he would treat Mis for half the fee. He had said Dr. Samuels was a clever man a (Robertson's) treatment was the same. He showed a letter Dr. Samuels saying how many treatments a week to give her

Mr. Howard read a letter from Dr. Robertson sayin did not know de Caux had been struck off the Register had made arrangements for de Caux to continue the treat while he was ill, in good faith. Dr. Robertson, who wa represented, told the council that de Caux came to se diagnostic apparatus. He had been mentioned by Dr. Sa and he had a "Harley Street" address. Dr. Robe declared that he had never said Dr. Samuels could cure ca Dr. Robertson added that he had been associated unregistered men ever since he took a degree in osteop He had resigned from the British Osteopathic Associati which he had been vice-president, because he had l serious disagreement with them about policy. He consi that medicine would absorb osteopathy. The council the facts alleged against Dr. Robertson not proved to satisfaction.

Geoffrey Roderick Richards, registered as of 26, Conn Street, Port Talbot, Glamorgan, M.R.C.S. (1937), appeared charge of having been convicted at Northampton on Ju 1946, on eight charges of failing to keep, in accordance the provisions of Regulation 11 of the Dangerous Regulations, 1937, a register in the form set out i second schedule to the Regulations, and of having bee victed on July 6, 1949, on five charges of unlawfully proc drugs. The council found the convictions proved, postponed judgment for two years.

James Thomas Wybourn, registered as of 67, Bid Mansions, Elgin Avenue, London, W.9. M.R.C.S. (was charged with having been convicted on May 31, at London quarter sessions. The case was heard in ca The council found the conviction proved, but did not Dr. Wybourn's name from the Register.

ALLEGED ADVERTISING

Eric Frederick St. John Lyburn, registered as of Spa (Tunbridge Wells) Ltd., Tunbridge Wells, M.B. Dubl. (was charged with infamous conduct in a professional re The charge concerned alleged advertising to procure pa and/or promote his own professional advantage. The plainants were the Medical Defence Union, who were sented by Mr. N. Leigh Taylor, of Messrs. Hempsons, soli

hing, or being bumped by somebody. It was not
d worthy of consideration that these trifling
ons mean nothing to non-hæmophilic people and
is impossible, in normal surroundings, completely
oid them. Nor was I ever praised for avoiding
catastrophes by prodigious efforts and continual
fulness. All blame and no praise produces appalling
piness, whether in a child or an adult, and makes
eel that he is indeed a "bleeding nuisance" to
f and everyone else.

the time I was seven I was able to report to the
s that my bleeding bouts came in fortnightly
. In one fortnight I bled seriously from even
ost trivial causes, whereas in the next fortnight
seriously only if the injury was severe enough to
bruising in normal people. But my perspicacity
nrewarded and nobody took any scientific interest
observation. It was not until many years later
worked out the precise periodicity of this monthly
so that now I know that there are twelve fort-
in the year when I must be extra specially careful
welve fortnights when I can relax my vigilance a
with progression and regression from one to the
; and I try to adjust my life accordingly. This
ly phase is complicated by a seven-year and other
sily recognisable phases. From my birth to the age
vas a bad time, from 7 to 14 was less severe, and
14 to 19 was very bad. Since then treatment has
it difficult to detect the seven-year phases.

issed something like a third of my schooling through
ecurrent hæmorrhages, and even when I could
l school the pain and discomfort, coupled with the
cteristic lethargy of the malady, made me often
ntive, for which the thoughtless and unimaginative
r was apt to punish me. In spite of these handi-
I always went to the top of the class in most
ets on the rare occasions when I had a fortnight
ore at school without interruption. It seemed a
and unjust reward for my efforts that my end-of-
reports invariably included the phrase, "This
has brains but is too lazy to use them." So nowa-
I find that my education is like a book with a page or
missing from every chapter. It is embarrassing
I am faced with some elementary mental exercise,
times so and so, and find that the 7-times table
nissing page in my knowledge, because I was away
a hæmorrhage when my class did that one.

e feeling that I was unpleasantly different from my
s persisted and was aggravated by day-to-day
rences. It was humiliating having to take a
to school asking to be excused all sports, after
l been desperately ill several times following trifling
lents on the field. As the headmaster was the
et-and-soccah type I became in his eyes something
r than the lowest form of animal life to the end of
chool days.

1933, when I was in my early 'teens, I was put in
pital ward with two other hæmophilics, and after
chats we realised with a wonderful sense of relief
we were not each a unique monstrosity, but that
e were others who led *our* sort of life and who had to
our sort of problems. I then and there resolved to
a club or society of hæmophilics in which each could
the other over their stiles. But alas for the resolves
hæmophilic! The exacerbations put paid to any
or project of this kind, and it was not until 1942
the International Hæmophilia Society was formed.
body but other hæmophilics seems willing to help us
h our difficulties. Help may be forthcoming once,
ce, or even thrice, but the hæmophilic's condition
everlasting, yet so erratic that he can be completely
ependent in the morning and bedridden and hope-
ly dependent on others by the evening, often without
rning, so that no provision can be made.

The worry and strain of this continuous Sword of Damocles hanging over the heads of hæmophilic families impairs any chance of social and domestic well-being. Then in adult life the inability of the hæmophilic to be a breadwinner all the time, though it is not his fault, often produces that sordid bickering state well known to social workers. Inevitably therefore the hæmophilic leads a lonely life, for his physical condition is too uncertain to enable him to go out or clear out, and *poverty, which is inevitably the lot of most hæmophilics,* makes it impossible for him to play host to anyone he feels an affinity for.

I am amazed how seldom the healthy and fortunate will help the disabled in the many ways open to them. For example, many people with cars know that I am often stuck in the house for days or even months on end while recovering from one of my heavier losses of blood, but they never offer to take me out for a change of scenery once in a while. Is it surprising therefore that the disabled hæmophilic becomes morbid when he sees cars floating by with bags of room for a disabled passenger?

It is only when the hæmophilic can afford to hire or own a car that pleasure and *regular* work are possible in his life. With a car to take him about the hæmophilic can hold down a full-time job for years, with little more than average sickness absenteeism, whereas the hæmophilic who has to rely on the vicissitudes of public transport cracks up in no time. A car is a desirable amenity to most disabled people; but to the hæmophilic it is a vital necessity.

Apart from the periodic lethargy that foreshadows a "bad" phase, hæmophilia does not impair one's physical or mental health unless some bleeding has taken place; and since bleeding occurs only as a result of trauma one has merely to avoid all trauma and one will prevent the consequent crippling and paralysis. Q.E.D. In practice, of course, it is impossible to avoid all trauma, but that should be the main aim of the hæmophilic's daily routine. Just as the diabetic has to adhere to a strict diet, so the hæmophilic must follow an equally strict anti-traumatic regimen. And just as the diabetic's blood-sugar level may go up unpredictably, so does the hæmophilic's blood-clotting function vary, often unpredictably (in my case, as I have said, there is a definite monthly phase). We hæmophilics have as yet no simple urinalysis to tell us when special care is necessary and there is a limit to the number of blood tests that can be taken day by day. So our life-long motto must be "eternal vigilance."

Of the 30-odd treatments tried on me, only one—an antihæmophilia egg-white derivative[1]—has stopped or prevented the bleeding as and when required. Of the remainder, sunlight, diathermy, physiotherapy, and vitamin concentrates have improved my general health, particularly during post-hæmorrhagic convalescence. Local styptics I have found useless and sometimes harmful. Blood-transfusion has a secondary anticoagulant effect in me and I have to refuse it. The benefits of manipulation can be more effectively obtained by safer means. Analgesics, though sometimes necessary, must be taken with caution; aspirin, for instance, is an anticoagulant and risky for the hæmophilic.

I am sure that clinical trials of hæmophilic remedies often fail because the natural variations in the disease are not taken into account. The hæmophilic usually reaches hospital in a "bad" phase, because that is when emergency hæmorrhages occur, and the improvement in blood-clotting which can spontaneously follow this phase may well be credited to the treatment applied. Conversely, if a treatment is tried when a "bad" phase is due it may be unfairly condemned.

---

1. Timperley, W. A., Naish, A. E., Clark, G. A. *Lancet*, 1936, ii, 1142.

that you have relinquished the procedure set out in the parts of the charge which have been found proved."

Dr. Lyburn asked whether, if he spoke as a politician during the coming election, he would be breaking the rules of the council, which he was loth to do? The President: You will have to decide that for yourself.

ADJOURNED JUDGMENTS

The council did not direct the registrar to erase from the Register the names of the following practitioners who appeared for postponed judgment: *William Melrose*, registered as of 15, St. Paul's Square, Liverpool, L.R.C.P.E. (1924); *Reuben Denny*, registered as of 64, Twyford Avenue, Acton, L.R.C.P.E. (1929); and *Archibald Thomas Macmaster Glen*, registered as of 16, Telford Avenue, London, S.W.2, L.R.C.P.E. (1935).

NAME REMOVED

Arthur Mervyn Rhydderch, registered as of Coppelia, Clements Road, Chorley Wood, Herts, M.B. Camb. (1937), M.R.C.S. (1926), had had judgment postponed in November, 1948, for two years, following convictions for driving and being in charge of a motor vehicle whilst under the influence of drink; he was directed to appear at the council's session in November, 1949. He had since been convicted for a different offence. After taking evidence *in camera*, the council directed the registrar to erase his name from the Register.

RESTORATIONS

The President announced the restoration to the Register of the names of *David William Jones* and *Duncan Metcalfe Morison.*

Council Affairs

Prof. R. J. Brocklehurst presented a report from the education and examination committees acting jointly. On the assumption that legislation might be introduced at an early date to give effect to the recommendation[1] of the Interdepartmental Committee on Medical Schools regarding compulsory house-appointments as a pre-registration requirement, the committees have held a preliminary discussion of the conditions to be attached to such appointments.

The committees recommended that the council should request the licensing bodies, as soon as they are in a position to do so, to furnish information as to changes made by them since the publication in April, 1947, of the recommendations of the council as to the medical curriculum, in the courses of study and examinations for qualifications conferring the right of registration under the Medical Acts. The committees also recommended that the council should resume the visitation of examinations for qualifications conferring the right of registration under the Medical Acts, and that the first should be on examinations in social medicine and public health, pharmacology and therapeutics, and forensic medicine.

The President presented the report of the Pharmacopœia committee, of which he is chairman. Sales of the new *British Pharmacopœia* from May to November, 1949, were 2739 copies, bringing the total sales to 38,182.

The British Pharmacopœia Commission has selected material to include in an *Addendum* to the *British Pharmacopœia* to be published towards the end of 1950. The commission has also reviewed the comments, criticism, and suggestions for the *British Pharmacopœia,* 1953, and drawn up a tentative scheme of contents. The commission has accepted an invitation from the Scandinavian commission to cooperate in the selection of names for new drugs. The commission has discussed with the Home Office the question of excess volume in ampoules. It regards this as an advisable and legitimate pharmaceutical practice, and it is hoped to overcome difficulties which have arisen in the administration of the Dangerous Drugs Acts.

STAFF APPOINTMENTS

At the end of the session it was announced that Mr. Walter Kinnear Pyke-Lees, assistant secretary of the council, has been appointed registrar in succession to Mr. Michael Heseltine, C.B., who is retiring not later than September, 1951. Mr. Martin Robert Draper has been appointed assistant registrar.

Letters to the Editor

ROYAL MEDICAL BENEVOLENT FUND

—I beg to remind your readers of the President's mas appeal (*Lancet*, Oct. 29, p. 814) as the gifts stributed before Christmas day.

will acknowledge that the winter months are ally difficult and hard for old people living on small es. I therefore ask those who are willing to help nd in ensuring extra comforts and cheer to its y beneficiaries to forward their contributions as as possible, marked "Christmas Gifts," to the i Medical Benevolent Fund, 1. Balliol House. r Fields, Putney, London, S.W.15.

C. LUTHER BATTESON
Hon. Treasurer.

HOSPITAL ADMINISTRATORS

,—Mr. Hackwood's letter of Nov. 19 demonstrates uncommon confusion between administrative and al staff. Staff engaged on purely clerical duties d be regarded as technicians in their particular cts. They bear the same relationship to their aistrative heads as, for example, laboratory tech- is bear to directors of pathology. The Bromley s apparently classify under the administrative ng those jobs which have an administrative content e clerical field, whether central or local, and are thus ctly expressed.

the general subject at the heart of Mr. Hackwood's , one has always looked to the voluntary teaching ital for medical freedom. Such freedom was not ely lacking in the municipal hospitals, and clearly as these hospitals turned towards clinical division. cal freedom (consistent with service good) is still i more important than administrative fancy, but oust know clearly what is necessary to ensure this lom. The medical advisory committee mechanism, ing parallel with the system of medical firms—the pattern of the "voluntaries"—should at the ient be adequate safeguard: and it is, despite icion to the contrary, completely proof against "lay ination," especially with medical representation on ital management committees.

he question should now be asked: is the coexistence 1) clinical division, (2) the medical advisory com- ee, (3) the medical superintendent, and (4) medical esentation at management-committee level likely to e clinical freedom? One among these is obviously of pattern, and it must be for the profession carefully onsider which shall go.

the final decision is that doctors shall administer, , logically, they should *completely* administer— ospital and at management-committee level. No tary can demur if this is, after full consideration. to be for the good of the service. But the question es again—would this spell medical freedom? What the clinicians think?

W. J. CRABB.

Hospital Management Committee.

"TEETHING POWDERS"

SIR.—It has been suggested that mercury poisoning y be the cause of infantile acrodynia, and that eething powders" are the source of the mercury.[1] It is difficult to reconcile the history of many cases of rodynia with mercury poisoning, and the proof has so r rested upon the microanalysis of urine. The interest used by this work, however, made us aware that ething powders are very commonly used.

With the help of members of the Kent child-health service an inquiry was made of 100 mothers of children aged 12–24 months attending five different clinics. Mothers of children of this age were chosen because the peak age-incidence of acrodynia is about 10 months, and it was hoped that memories would be long enough to cover the second half of the first year.

The results have been interesting. More than half the infants (53) were given such powders. The most popular powder in use is one containing calomel (48 cases): grey powder was used for 4 infants. Powders were frequently given in the first few weeks of life and continued for months as a weekly dose. The reasons for using powders varied from "the mother has great faith in them" to more specific reasons such as "fretful with teething," irritability, restlessness at night, sore gums, constipation, or digestive upset. The advice to use the powders was offered 18 times by a grandmother, 18 times by a neighbour or friend, 4 times by a doctor, 3 times by a chemist, and once by a midwife. The families were evenly divided between town and country, and the proportion of powder-users in the two groups was the same. None of the children developed symptoms of acrodynia; as might be expected, the few children reported to be victims of infections and who failed to gain weight regularly, were mostly powder-takers.

Farnborough Hospital, Kent.

DUNCAN LEYS.

ÆTIOLOGY OF PEPTIC ULCER

SIR,—One can readily agree with the comment in your leading article last week that the evidence brought forward in the same issue by Dr. Doll and his colleagues need not be interpreted as supporting the hypothesis that hypersecretion is the cause of chronic peptic ulcer; but this does not mean that either the opposite view or the suggestion which you have advanced are satisfactory alternatives. It will be generally agreed that the answer to a medical problem should, whenever possible, offer a physicochemical explanation, and one may therefore leave "autodigestion" and the "inborn diathesis" out of discussion because biologically they are unsound arguments and in any case they only remove one difficulty to replace it by another one.

The fact that chronic ulcer is invariably associated with high acid values has led to the unwarranted generalisation that excess of hydrochloric acid is the only factor in the causation of all types of chronic ulcer. There is no difficulty in accepting the acid factor as the cause of the œsophageal, jejunal, and Meckel's diverticulum ulcers, which belong ætiologically to one category of lesion: but, a priori, hydrochloric acid cannot by itself produce the ulcers situated in the stomach and first part of the duodenum, which belong ætiologically to a different category of lesion. There is experimental evidence to support these theoretical considerations. This distinction in the classification of ulcers is of fundamental importance, for it leads to the inescapable deduction that there must be a second factor in the production of the latter type.

Since hypersecretion always accompanies the active ulcer, it is necessary to define in what relationship they stand to each other. Hypersecretion forms a constituent part of the "syndrome of hyperfunction" which embodies the normal reaction of the stomach in response to a stimulus; the persistence of an unusual stimulus produces the exaggerated physiological response which becomes a pathological entity. The syndrome of hyperfunction—which is pathognomonic of the disease—is an expression of a state of irritation which appears as a functional disorder in the period of transition before the establishment of the organic lesion—i.e., it represents the pre-ulcerative stage.

In England Now

A Running Commentary by Peripatetic Correspondents

"It takes a fortnight to cure a cold; if you leave it alone it gets better in two weeks." I have just learnt the sad truth of this cynical statement. As I woke up this morning with a streaming cold I recalled a recent article saying something like: "The initial stage of a cold is an allergic reaction which in nearly 98% of cases can be instantaneously cured with antihistaminics." I had only to reach out for the latest sample, and down went an enormous dose. It put me to sleep for several hours but left my cold wide awake. The local chemist tried to be helpful: "A thousand milligrammes of ascorbic acid will soon get rid of your cold," he advised, and made me swallow twenty tablets of vitamin C every few hours. My friend, the physiotherapist, was very sorry to hear that I had a cold. "Some U.V.L. and local short-wave will soon fix it," he pronounced cheerfully and proceeded to treat me with childlike faith and conviction. Home at last, after a busy surgery where the treatment of colds was the main item on the agenda, I placed myself again in the soporific arms of antihistaminics, endured the astringent taste of ascorbic acid, and was just about to try a new vasoconstrictor on my nasal mucosa when my wife said: "Take two aspirins and a hot drink and you'll be cured tomorrow." Tomorrow? From tomorrow it will be only thirteen more days to go. . . .

* * *

The method of writing to the family doctor on the discharge of his patient from hospital is changing. Instead of the informal chatty letter, the modern habit is to despatch a scientific summary, resplendent with biochemistry but stripped of humour and intimate clinical details—a dull document. Fortunately, in acting as scribe (or registrar) to the firm, I have been set a high standard of the older school of writing by my chief. May I give you an example? The professorial hand wrote as follows:

Dear Dr. X,

Thank you for referring Mr. Jones to me; a dear old man, who told me, and I have no reason to doubt it, that he is 86. He opened his story with an account of how, in the earlier part of the eighteenth century, there was a medium who, under suitable condition of trance, would float out of the window feet foremost! Mr. Jones claims kinship with this gentleman, because at certain periods of his life he too has had the sensation in dreams that he was, in fact, floating feet foremost out of the window. The connexion between this and his supposed tapeworms was a little obscure, and though he said the story was of the first importance I would not quite see it. The evidence that he has any tapeworms is meagre in the extreme; they have never been seen, but he has apparently a voracious appetite, he picks his nose, and he passes his motions fairly frequently!

This man, my dear X, is as mad as a hatter. He is suffering, as you say, from senile dementia, and his tapeworms and his floatings out of the window are alike evidence of the state of his mind. Actually, when not obsessed by these episodes he is a very pleasant man, with a good sense of humour, and physically extraordinarily fit. He has, of course, a good deal of atheroma, a large heart, and a blood-pressure of 200/90. Nothing was to be felt in the abdomen or in the rectum, and the prostate is small and firm. He has some infection of his water, which was turbid, but generally speaking he is very well.

I told him that there was no evidence that he had a tapeworm, that I was well aware that people could be obsessed with the idea when they had not, but that when I came back from my holiday, if he was still of the same mind, I would take him into hospital and do such tests as might impress him that there was no need of a vermifuge. I did, however, emphasise that the treatment for worms was somewhat exacting, and that I felt very strongly that in a man of his age nothing ought to be undertaken without the very clearest evidence. We parted on admirable terms and I enjoyed the interview.

With kind regards, &c., &c.

Then, when Mr. Jones had been duly investigated:

Dear Dr. X,

Mr. Jones is leaving hospital tomorrow, and will ultimately find his way no doubt to Sidmouth, there to spend the winter. I am glad to report that we have found no evidences w of a tapeworm or the ravages thereof. The only t found was some infection of his urine, which we on the whole better to ignore at his age, as it is sym and would almost certainly recur if treated.

He is in good shape and seemed relieved at our There have been no junketings, the windows of the have been strictly watched at night, and I can rep complete veracity that he has not appeared in any form proceeding feet foremost into the night air. we have every reason to believe that he has slep in his bed. This statement you will, I am su reassuring.

Yours very sincerely, &c.

No doubt in the future, when we have been sul by bureaucracy, we shall fill a discharge form of writing either a letter or a summary, and this appear as follows:

Diagnosis: Neurosis (obsessional). K.
Investigations: Examination of fæces. T.3
No ova of *Tœnia solium* detected.
Treatment: Reassurance. Q.
Psychiatrist if necessary. X.

* * *

I watched my colleague nonchalantly absor third cocktail and was reminded of the occasion s years back when I had to decide whether or exsanguination resulting from his last hæma called for immediate transfusion with the possil a gastrectomy later. "Your husband seems ver I remarked to his wife. "Did he ever have tha tion?" "Oh, no," she replied, "he never h operation and he's been fine for years now. W he couldn't live on exactly the same diet as of the family and we didn't fancy living all the the diet that suited him. So whenever we were roast duck or pork and stuffing or something li I always arranged for him to have a suitabl elsewhere, and before he came back I used to o windows and give the place a good airing. On the smell was really too much; my husband is a iron will but it isn't in human nature to hold of meal once you've had the smell of it. And I love co Elementary, my dear Pavlov. But how comes nobody has enunciated this essential principle treatment of duodenal ulcer? It ought to be in textbooks.

* * *

Conditioned reflexes can sometimes be a nuisa our family has recently learnt. We've just ha lighting installed, including a pull-switch in the la put in to prevent one getting a shock by touchi ordinary sort of switch while making contact wit —surely rather a difficult thing to do, anyway also have the old-fashioned pull-chain to the f tank, and the snag comes when we are in a hurr dark, and we are ready to leave. Sometimes I've light off hurriedly, realised I did not mean that, the light on again in mistake, flushed the tank, the light again, turned to the tank because it worked, and by then been in such a frenzy th tugged at both, rapidly and indiscriminately. O disgust my wife rushed out, leaving the light o waving the chain like a flail (she had pulled it off zeal), swearing she would brain the electrician. electrical companies really need a consultant physi to show them how to avoid these irritations.

cutive in the factory whom I considered to be in a n to know the true facts; these were stated in my paper.[4]

findings in my last paper [6] enable me to refute Dr. ston's suggestion that the massive lesions are originally ilous. Serial films on several cases published in my show unequivocally the development of massive subsequent to those of a miliary snow-storm type. ure Dr. Heppleston will agree that this miliary form, nown in other types of pneumoconiosis, had nothing ever to do with tuberculosis. There is no evidence now that this miliary appearance may not be due to the tion of silica. Thus, the massive lesions, being a later of the miliary, are also not tuberculous; and in keeping this are my clinical and pathological observations. case reported [6] the patient for some years before his brought up large amounts of black graphite sputum; one time his films showed a rather large cavity within assive shadow.[3] No tubercle bacilli were found in the n which came from this massive lesion, regarded by epplestor as originally tuberculous; and this lesion und at necropsy to be a cyst filled with black fluid. ermore, no evidence of tuberculosis was detected in the of this man either macroscopically or microscopically. eppleston may contend, as he did in his letter, that ng of fibrous tissue is not necessarily indicative of the of free silica, since exactly similar effects may be ced by healed tuberculous foci. Being a physician I to leave the controversy in such matters to the patho-, but I am doubtful whether many experts in the logy of occupational lung diseases would agree with

The second question raised by Dr. Heppleston is whether graphite can produce pneumoconiotic lesions. In my here are manifestations of fibrosis which I am inclined ribute to silica, and others which are mere deposits of ite. These observations are by no means sufficient ide the rôle of pure graphite. This can only be proved orough animal experiments conducted for long periods. is way it might also be shown whether or not tuberculous s are indispensable for the development of pneumosis due to graphite with and without silica. But such iments can provide proof only if the animals have inhaled ite dust. Graphite suspended in oil injected into the via the trachea gives, in my opinion, no conclusive nce.

erculosis Dispensary, Hull. LASAR DUNNER.

ANONYMITY IN BROADCASTING

R,—The report in your last issue that a well-known ician had been televised delivering a talk on his al subject prompts me to draw attention to the tic state of practice with regard to the publication e names of medical broadcasters. I was recently d to broadcast on a subject only partly connected medicine and I was urged by the B.B.C. to allow name to be published. Before answering I sought e. The General Medical Council refuse to advise pecific questions and merely draw the attention of inquirer to their warning against advertising. An ority on professional ethics strongly advised st publicity. "The present embargo," he said, ridiculous and will not be lifted until sufficient rs have defied it; but don't take the risk yourself!" he series of broadcasts in which I took part some ors remained anonymous and some did not.

t will not the G.M.C. at least tell us what they rstand by advertising? The public today seeks ation on medical and allied questions. The B.B.C. aking a serious attempt to supply the need. It is an nature to wish to know who is the authority to m one is listening. Is it advertising if a doctor, out recommending himself in any way, allows ame to be published in these circumstances? And is ir that he should not know the answer until someone plains about him to the G.M.C.?

ay I, Sir, preserve my anonymity and remain

IGNOTUM PRO MAGNIFICO?

B.C.G. VACCINATION

SIR,—I cannot lay claim to much personal experience of B.C.G. but I have had a considerable experience of vaccination with the vole acid-fast bacillus, and it is reasonable to assume that these two avirulent strains act in very similar manner. From what I have seen in a few animals vaccinated with B.C.G. and in many animals vaccinated with the vole bacillus, I believe that B.C.G. vaccination can in fact reduce the morbidity and mortality rates for primary tuberculosis, but what I have seen also makes me firmly convinced that there should be no yielding to any clamour for the general release of the vaccine in this country.

Without entering into the controversy that has arisen over the statistics which have been cited in favour of B.C.G. vaccination, I should like to draw attention to the fact that even if these statistics were generally acceptable as adequately controlled, all they could serve to show is that vaccination can raise the resistance of susceptible subjects for a certain space of time. Any enhancement of resistance following vaccination which is demonstrable over the periods of time covered by the statistics could be due to the direct effect of the vaccination itself. There is nothing to justify any conclusion that the temporary protection given by the vaccination has been converted to something in the nature of a lasting immunity as a result of a fresh stimulation of the defence mechanism by virulent tubercle bacilli gaining access to the tissues.

In the guineapig and in the cow there is a period after vaccination during which resistance to virulent bacilli is notably enhanced; but sooner or later—sooner in the guineapig and later in the cow—resistance falls away to reach, in some animals at least, a level below that observable in any of the control animals. The fact that resistance in the vaccinated animal can fall eventually to a level below that of the unvaccinated animal is disturbing; and it is not peculiar to animals vaccinated with the vole bacillus, for E. A. Watson reported similar findings in long-term experiments with B.C.G. in cattle to the 12th International Veterinary Congress in 1934. It is strange how lightly this worker's results have been dismissed and how the lesson to be drawn from them has been ignored.

From early times we have been taught that man's allotted span is threescore years and ten; yet how many of the adequately controlled statistics advanced in support of B.C.G. vaccination in man cover a space of time approaching even one of these three and a half score? When the differences between the normal life-spans of the various species are taken into consideration, it becomes evident that the periods of time for which statistics are so far available in the case of man are comparable only to those periods of time during which resistance is still enhanced as a result of vaccination in the case of animals. There may still come a time—20, 30, or 40 years later—when there will be a rise in the morbidity and mortality rates for the older age-groups as a late, but nevertheless direct, result of imperfect vaccination in early life.

Far from there being no necessity for further controlled experiments in this country, it would appear to be a moot point whether it is ethical to carry out, under the assurance that the vaccine is harmless, any experiments at all on human beings so long as the various factors underlying infection with, and resistance to, tuberculosis are still too imperfectly understood to justify the use of what might yet prove to be a two-edged weapon.

Nature is conservative in her methods, and while it is true that man has a greater capacity than the lower animals for developing a lasting immunity when exposed to infection with virulent bacilli, his reactions to vaccination with an avirulent strain must be similar to those

It has been shown experimentally that a physical agent is not involved in the production of the initial injury, but evidence is now accumulating that a chemical factor other than hydrochloric acid may be responsible for the primary trauma. But whatever this may be, there can be little doubt that hypersecretion precedes the lesion, and that they are both-produced by the same morbid process and one is not responsible for the causation of the other.

London, W.1. J.-JACQUES SPIRA.

PATHOGENESIS OF ATHEROSCLEROSIS

SIR,—In an investigation, during the last two years, of the problem of aortic atheroma I have had many opportunities of verifying the correctness of the views expressed by Professor Duguid in his article of Nov. 19. It would be a pity, however, if, in recognising the thrombotic nature of most atherosclerotic plaques, we were induced to abandon completely the facts accumulated by the "degeneration" and "overgrowth" schools of thought. The antithetic tendency in the development of medical science is almost irresistible, but true progress is only achieved by attempting synthesis.

The incompleteness of Professor Duguid's explanation, to which he himself draws attention, is best shown by reference to the peculiar distribution of atherosclerotic lesions, which are found in arteries rather than in veins, in certain arteries rather than in others, and in characteristic positions within these arteries rather than diffusely. If thrombosis accounts for the formation of these plaques, clearly there must be factors which predispose to thrombosis in these selected places. The almost invariable reason for the formation of a circumscribed mural thrombus is disease of the underlying arterial wall—disease which usually first manifests itself to the naked eye as a spot or streak of "lipoidosis." This lesion, as Professor Duguid points out, cannot satisfactorily be explained by the thrombotic theory.

The results of my own investigation may not be published in extenso for some time to come, and I would therefore be glad of an opportunity of briefly stating my main conclusions:

> It appears that the human arterial tree is not perfectly adapted to the normal mechanical demands made upon it. This maladaptation is especially pronounced at the sites of maximum mechanical stress. In these places, from a very early age, foci of lipoid degeneration appear, as the result of an absolute or relative excess of plasma constituents. Resorption of these lesions ceases after the age of 25, and thereafter the foci increase in size and pass successively through the stages of fibrosis, vascularisation, and ischæmic necrosis. It is over these lesions—more especially in their necrotic end-stage (when they release thromboplastic substances)—that mural thrombi tend to form, which either in themselves or by their organisation are responsible for most of the clinical effects of atherosclerosis.

These conclusions, based on analysis of 300 cases, combine the views of Rokitansky, Virchow, Anitschkow, Moschcowitz, Winternitz, and Duguid into an integrated picture of this disease-entity.

Professor Duguid's hæmodynamic argument against the possibility of intimal overgrowth is not acceptable. He has succumbed to the myth of the pulse-beat. The pulse as felt in healthy people is an artefact produced by digital compression of the artery. Except the aorta, normal arteries do not contract and expand rhythmically, being kept at a constant calibre by the contraction of the medial muscle. In emphasising the elasticity of arteries, Professor Duguid tends to overlook their muscularity. Intimal overgrowth can and does occur. That the basis of such growth may be an accretion of fibrin with subsequent organisation is interesting and important but does not present a striking departure from the mode of fibrous-tissue formation.

These critical remarks are not intended to from my opinion that, in demonstrating the thro nature of the clinically significant atherosclerotic Professor Duguid has made a contribution of t importance and one which in its therapeutic ap may become the source of the greatest benefit.

Gerontological Research Unit,
Edinburgh University.
ERICH GEIRING

SIR,—Professor Duguid quotes as his example trating the thrombosis hypothesis a thrombosis coronary artery. If this were true, surely one expect evidence of myocardial infarction—na fibrosis—in association with the atherosclerosis. states that "coronary occlusion may occur wi myocardial infarction if the process is slow in dev ment or (and) the collateral circulation is adequ This statement would support the production of com occlusion by atheroma which progresses slowly than by a process of thrombosis. Thus it is diffic believe that if a mural thrombus were formed in an as small as a coronary it would not rapidly increa size and occlude the lumen, producing infar Undoubtedly in cases of adequate collateral circul infarction would not occur, but to prove the hypot one would have to find some correlation between at sclerosis and myocardial infarction—that is, an in pletely occluded coronary artery with approp changes in the myocardium indicating previous com occlusion which became recanalised. However, so atherosclerosis alone is found.

The work of Professor Duguid indicates that formation of atherosclerosis from a mural thromb the method by which a thrombus in the intim organised. May not this phenomenon still be rega as a process which increases the degree of atheroscle previously present rather than acting as a pri cause. It may be possible to correlate these "p logical conditions in which the tendency to thrombo unduly increased" with the severer states of at sclerosis.

GRAPHITE PNEUMOCONIOSIS

SIR,—In his letter of Nov. 19 Dr. Heppleston dis the pathology and pathogenesis of graphite pne coniosis, which was the subject of a leading articl your issue of Sept. 17. I should like to make following comments.

1. Dr. Heppleston distinguishes two types of lesion graphite pneumoconiosis: (*a*) small lesions consisting small focal collection of black pigment with little fibrosis a distinct focal emphysema; and (*b*) a pigmented ma dense fibrous tissue sometimes showing colliquative necr He regards the massive lesions as infective in nature as far as I understand, basically tuberculous. He justified in applying his findings on coal-workers to grap workers.

In the graphite problem not only the pathological histological findings are important, but also, in my opin the clinical findings and still more the radiological finding serial X-ray films. Your leading article mentions the arti by Gloyne and his co-workers[1] and Harding and Oliver.[2] article mentions only the first of my own papers,[3 4 5 6] that I was the first to publish a report on graphite pneu coniosis. As to the purity of graphite, I was under a apprehension at that time, but not, as you state, becau was misinformed by the workers (whose unconfirmed op I would not have relied on). My information in fact came fr

ng at least 400 toxic exposures to high pressures gen I did not once observe myoclonic movements h arms as the sole symptom of oxygen poisoning. ly subject showing myoclonic movements in one subsequently had a typical jacksonian attack.

lly I would suggest that intermittent oxygen y is far safer in this type of case. Study of the l-blood carbon-dioxide tension, or content, will o determine which patients are in the greatest of carbon-dioxide narcosis.

nte of Diseases of the Chest,
London, S.W.3.

KENNETH DONALD.

—Dr. Davies and Dr. Mackinnon are being misled ir observations on but two cases.

tly, when congestive cardiac failure has overtaken nphysematous subject it is a matter of clinical ation that death may take place suddenly, as in ase 2, even though no oxygen is given. In the l place, when the anoxia is severe clonic limb nents are seen, which disappear in the oxygen nly to reappear out of it. Thirdly, the post-m brain findings, if closely resembling those bed by Hunter,[1] are certainly not the rule in cases physema dying of congestive heart-failure.

ally, the life-saving value of oxygen therapy in poor unfortunates with complicated emphysema oubted, so let us forget about oxygen poisoning.

e Farm Hospital,
ield, Middlesex.

THOMAS SIMPSON.

—The article of Nov. 12 by Dr. Davies and Dr. nnon is of very great interest. We have had lerable experience in this school of studying the nses of emphysematous subjects to oxygen, and ally speaking the reaction is beneficial, oxygen ation of the arterial blood rising with accompanying tomatic improvement. It is admitted, however, it is often impossible to achieve a normal arterial n saturation in an oxygen tent, and there are ions on which the mental symptoms persist ically unchanged.

have observed a few rare instances in which al venous engorgement going on to papillœdema retinal hæmorrhages has complicated the re: the cerebrospinal-fluid pressure in such nts is very high—over 300 mm. water in one case. patient came to post mortem: there was swelling œdema of the brain with widening of the Virchow-n spaces, into some of which recent hæmorrhages taken place. These changes closely resemble those in your contributors' case 2, though the effused d had not yet reached the subarachnoid space. patient (case 3 of Howarth et al.,[2] and also case 3 mpson[3]) had been treated in an oxygen tent mittently over a period of two months before death, he cerebral symptoms were those of steadily advanc- mental confusion and clouding of consciousness, h appeared before admission and which, if little oved, was certainly never made worse by oxygen. e is nothing in the history of this case to suggest the lesions were produced by oxygen therapy.

ach winter brings a dozen or so cases of emphysema rt-failure to autopsy in this hospital, nearly all of m having been treated by oxygen, and the occurrence he lesions in the case here described, so far unique ur experience, seems to be ascribable to some factor er than oxygen therapy. The clinical picture of mphysematous encephalopathy" with papillœdema l high cerebrospinal-fluid pressure may develop ependently of therapy.

The observations of Davies and Mackinnon emphasise the complexity of the problems involved in the cerebral adaptations to emphysema. We shall certainly look forward with interest to their future reports, and meanwhile keep a closer watch for any adverse influences of oxygen administration.

REGIONAL PSYCHIATRISTS' ASSOCIATION

SIR,—At a meeting in London on Nov. 22 it was agreed that an Association of Psychiatrists of the South West Metropolitan region be set up to replace the old psychiatric advisory group of this region. A draft constitution was discussed and approved. It is proposed to send a copy to all psychiatrists working in the region, who will be invited to join the association. The acting treasurer is Dr. D. N. Parfitt, Holloway Sanatorium, Virginia Water, Surrey.

Belmont Hospital,
Sutton, Surrey.

D. SHAW
Acting Secretary.

CONTROL OF TUBERCULOSIS

SIR,—Recent letters emphasise the fundamental dichotomy in the approach to this problem in Great Britain. The basic problem is shortage of beds in sanatoria and hospitals. This, combined with the alarmingly large number of deaths from tuberculosis—400 per week—and the fact that half of these deaths occur within one year of notification, should bring together the tuberculosis officer and the chest physician for a common concerted attack. The tuberculosis officer is primarily concerned with the patient who should go into a sanatorium; but until that happy and usually far remote day, the patient must be kept under observation, and if possible given some form of treatment. Furthermore—and this is of paramount importance—the patient must be made as little a risk to his family as possible. On the other hand, the physician at the sanatorium is interested in curing each patient that comes into his hands, knowing that the risk of infecting others and the patient's family is considerably reduced during his stay in a sanatorium.

It has been suggested by some correspondents that if collapse therapy is carried out in the patient's home with adequate care, on suitable cases, very often the patient's condition can be improved and his stay in a sanatorium considerably reduced. This in turn leads to an increased turnover in sanatorium beds. More important, however, the infectivity of the patient can be reduced, and, as a source of infection, he can be brought under early and adequate control. In blunt terms, it is probably more important to control the patient as a source of infection than worry about complete cure, although a cure must always be the ultimate aim. Awareness of this was the basis for beginning domiciliary collapse therapy in many dispensaries such as those of Bermondsey, Southwark, and Ealing. I had an opportunity of working with Dr. E. K. Pritchard at Southwark, and believe that his results amply justify the method.

In this country Myers, in 1920, faced with the problem of a large number of sputum-positive patients in the community and inadequate facilities for treating them, tackled the problem by: (1) prevention by early treatment of patients of the reinfection type from becoming infectious; (2) isolation of the infectious in the sanatorium or home; and (3) eradication of tuberculosis in cattle. The success of his programme was mentioned in THE LANCET two years ago.[1] Tice,[2] faced with a similar problem, began in 1931 a programme of collapse therapy in the home and of B.C.G. immunisation. He states that "collapse therapy is more perfect and complete than any isolation." He found that the sputum became negative in 83% of patients with minimal disease, 76%

of the lower animals. Man's greater resistance to virulent tubercle bacilli must lie in his greater capacity to deal *with the substances which are responsible for their* virulence; and from analogy with other infections it seems fair to assume that these substances are antigens and that man has a greater capacity than lower animals for developing antibodies for these antigens.

Both avirulent and virulent bacilli will produce allergy (to use this term in its widest sense of altered reactivity), but in addition virulent bacilli will stimulate the formation of special antibodies. It is important, however, to realise that in infection of an unvaccinated person with virulent bacilli, *antibody formation must be* a phenomenon which proceeds concurrently with, and not in succession to, the development of allergy. The development of allergy cannot be regarded as a stage towards the development of antibodies. In fact, in a vaccinated person the multiplication of virulent bacilli is held in check and therefore less antigen will be available *for the stimulation of antibodies.* There is a *grave risk* that, for the sake of the few who have so little resistance that they cannot survive a primary infection, the future of the many, who could have overcome the primary infection in a perfectly adequate manner, may be endangered.

Further research there must be before vaccination can be adopted as a rational procedure, but let it be intensive and coördinated research attacking the problem from all angles simultaneously. We must learn more about the development of allergy, and we must learn more about the antigenic properties of various bacterial fractions. If the latter cannot be studied in the usual serological manner, there are still the possibilities of tissue-culture to be explored. Above all, the physiological basis for natural resistance must be sought; for herein lies the key not only to prophylaxis but also to *treatment.*

MEGAMYELOID CELLS AND AMINOPTERIN

SIR,—In the bone-marrow of mice during acute intoxication produced by large doses (20 mg. per kg. *body-weight daily for three days)* of 'Aminopterin' (4-amino-pteroylglutamic acid, kindly supplied by the Lederle Co.), we have observed, in addition to the almost complete disappearance of the granuloblastic, erythroblastic, and megakaryocytic series, the appearance of large myeloid cells with a budding nucleus. Similar polyploid cells have been observed by us in acute poisoning by benzol[1] and mustard-gas derivates,[2] but in animals treated with aminopterin they are more characteristic and frequent.

These cells have the following characters: (*a*) large size (their dimensions being sometimes those of mature megakaryocytes); (*b*) irregular shape of the nucleus; and (*c*) fragility (these cells often have ravelled borders and many cytoplasmic and nuclear vacuoles).

These large myeloid or "megamyeloid" cells represent various types of myeloblastic, promyelocytic, or myelocytic gigantism. Probably these elements are produced owing to the underlying disorder of the division process of the myeloid cells; they are perhaps the *ultimum moriens* of the granuloblastic source of the bone-marrow.

Knowledge of such megamyeloid cells in extreme experimental conditions should make easier the interpretation of *similar cells described in cases of aplastic* myelosis and acute or subacute aplastic leucosis.

NEUROLOGICAL EFFECTS OF OXYGEN

SIR,—I have read with *great* interest the artic Dr. Davies and Dr. Mackinnon in your issue of Nov and I would like to make a few comments.

A number of workers (Barach, Richards, Cour Comroe) have described the syndrome of carbon-di narcosis when oxygen is administered to patients chronic lung disease, arterial anoxia, and car dioxide retention. Recently I studied such a pati with severe emphysema and mild heart-failure, lapsed into coma after 12 hours' oxygen therapy. this time his arterial pressure of carbon dioxide (pC was 120 mm. Hg. After the withdrawal of oxygen recovered rapidly with an abrupt fall in his arte pCO_2. It was indeed a strange sight to see him beco almost black and then recover consciousness. Se weeks later, when the pulmonary infection for which was being treated had subsided, the arterial pCO_2 beca *steady at 60 mm. Hg.* It is thought by some carbon-dioxide retention will remain more ma after such an episode.

The most favoured theory concerning this syndr is that these patients are so well *buffered* that they relatively insensitive to carbon dioxide (Scott), and th their respiratory activity depends mostly upon ano *stimulation* of the *sino-aortic* zones The removal the anoxic stimulus causes them to hypoventilate further retention of carbon dioxide. It can be e verified that many such cases do greatly decrease ventilation when breathing oxygen. Barach and Rich (personal communication) have tried to count the respiratory acidosis in such patients during oxy *therapy* by exhibiting ammonium chloride, but procedure upset them even more.

Kety and Schmidt have demonstrated the very lar cerebral blood-flow in severe emphysema. They assum that this is due to cerebral vasodilatation caused by high body pCO_2. This increased blood-flow may ca excessive production of cerebrospinal fluid (C.S.F. When a raised venous pressure is also present, then th may also delay absorption of C.S.F. *If the body* pC rises shortly after the commencement of oxygen breathin then the further vasodilatation will result in an increas quantity of blood *in* the cerebral circulation, an a rise in C.S.F. pressure will follow from mechanic causes alone, the cranium acting somewhat like plethysmograph.

I cannot agree that oxygen poisoning, as usuall described, should be incriminated. Campbell's expe *ments showed that* there is only a small rise in th *tissue carbon-dioxide* tensions when *normal* animal breathe comparable percentages of oxygen *for* ver long periods; and in any case the sharp difference between oxygen poisoning and carbon-dioxide intoxic tion makes Gesell's theory *unconvincing.* Furthermor recent research has not supported his thesis. Whi

ot think it would impose an impossible burden
school doctors. To skin-test a batch of people
a very formidable or lengthy business. and it
ot actually be done by a doctor though perhaps
she should read the result. The task of inter-
; the films of the positive reactors would not fall
school doctor.

ay be argued that it would be better to X-ray
leavers "just to make sure"; but this would
belittle the value of the Mantoux test, and to
attention from the need for X-ray examination
Mantoux-conversion takes place. Everyone work-
tuberculosis must be sadly familiar with the false
of security engendered by the single X ray, taken
nths or a year before, which was "all right,"
erefore led to disastrous delay in seeking advice
symptoms arose. It is true that a misleading
ve reading may be found while allergy is develop-
r because the patient has measles or miliary
ulosis: but there are snags with any routine test.
formidable part of the business would be in keeping
with and re-testing the negative reactors after
ave left school, and have become so very elusive.
ve might take heart from the satisfactory change in
blic mind towards diphtheria inoculation, and hope
his aspect of the campaign against tuberculosis
lso be generally accepted. Skin-testing is less
to create a tuberculosis-phobia than resort to
ed "blind" X-ray examinations. In any case,
G. is to come into its own in this country, extensive
ux-testing will have to be done.

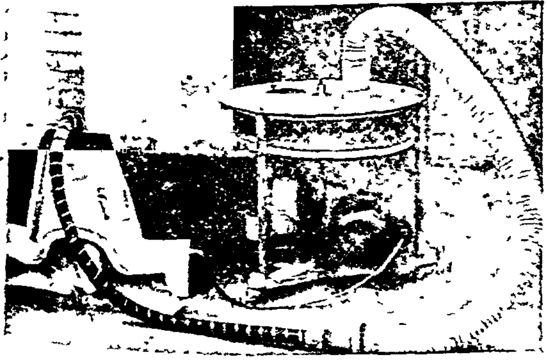
ell Hall Sanatorium, Sussex. RUTH DINGLEY.

IMPROVISED MECHANICAL RESPIRATOR

—The following account of an improvisation to
protracted treatment and nursing in a box-type
nical respirator may be of interest.

irl, aged 14, was admitted to the Coventry Isolation
tal on June 18, 1949, with acute anterior poliomyelitis
ing all the limbs and the back. Next morning the
sis had spread to all the muscles except those supplied
cranial nerves and the flexors of the fingers. Respira-
diaphragmatic and intercostal. was grossly impaired
apidly became virtually non-existent. The patient was
l in a Both (Nuffield) box-type respirator and remains
still. To date there is some return of power in hands
rists and of a small but inadequate degree of intercostal
ment. The patient still cannot remain without the
ance of the respirator for more than a minute, or at the
le two minutes, without grave distress.

ter a few weeks the difficulty of giving physiotherapy
e limbs became an insistent and worrying problem.
rovide oxygen through an Oxford inflater for longish
ds seemed hardly the solution, though this apparatus
proved very useful. especially in the earlier weeks,
aking more feasible brief nursing procedures—e.g.,
ging the bedpan—which had to be carried out with
tmost dispatch by an organised and practised team of nurses and doctors. On the other hand, to transfer the patient wholly from her safe and life-saving Both respirator to some other type of respirator, which might leave the limbs accessible, was much too risky. Even if one could get such a respirator applied in time, which was very doubtful, it was uncertain whether the patient would tolerate it.



With this problem in mind, and having read Dr. Ursula Blackwell's article in *The Lancet* of July 16, 1949 (p. 99), the patient's father, who is connected with the Coventry engineering industry, and one of us (J. F. G.) visited the Western Hospital, Fulham, where they were kindly allowed to inspect the hospital's comprehensive collection of mechanical respirators. In particular from their Stille respirator we acquired the basic idea of a rigid suction chamber sealing over the patient's trunk, and we noted how the Stille shield had been adapted by the hospital staff with a Both motor and bellows unit. The father then set to work, with the help of a firm of pattern-makers, to construct a wooden mechanical respirator that would (1) fit over the chest and upper half of the abdomen only; (2) leave the limbs free; (3) fit over the respirator mattress so that the patient, having been drawn out, could yet remain secure in the Both respirator attachments, and if anything went amiss, could be promptly sealed up again in the box respirator in a matter of seconds; and (4) work off the box-respirator motor and bellows unit. A rubber valve and manometer similar to the Both were also planned to be fitted.

The sealing of the respirator round the patient to make an adequately airtight junction was the greatest single difficulty. It was solved by two devices: (1) The new respirator was made to measure, both to the patient and to the Both respirator mattress. Malleable lead strips were quickly moulded round the upper part of the chest, the axillæ, and the middle of the abdomen to obtain the relevant silhouettes. (2) A thick layer of 'Sorbo' rubber was fixed to those margins of the respirator which fit on to the patient. The sorbo was found to be appreciably porous to air, so, to overcome this, thin rubber aprons were fitted to the inside of the new respirator and carried round the sorbo. The free edge of this rubber sheeting, when tucked round the patient, assisted the sealing. This seal was completed by several pads of cotton-wool and (underneath) by the sorbo mattress supplied with the box respirator. The rubber bedpan, on which the patient lies, is removed when the patient is in the new respirator. To ensure that the respirator worked, and to make adjustments, experiments were made with a volunteer about the same size as the patient.

The respirator (see figure) is used daily for about twenty minutes, during which period the patient has massage and passive movements. The longest time the new respirator has so far been in use is half an hour, but there seems to be no reason why it should not remain on for very much longer, given full psychological tolerance. Unfortunately. this is not yet forthcoming, partly because the patient feels safer in her box respirator, and partly because she associates the new respirator with a degree of pain and discomfort inseparable at present from her passive movements. There is also a sensation of pressure across the abdomen when the respirator is working efficiently, especially during the phase of greatest suction.

The new respirator can be applied effectively in a few seconds by a minimum of four persons, but the patient must be lying squarely and centrally on her sorbo mattress, and the operators improve with practice. Of the four persons, two handle the respirator, one manages the arms, and the fourth attends to the hose and bellows. The respirator works well, but rather more suction is needed (18–20 cm. of water) to maintain the patient's colour than in the box respirator (14 cm. of water), possibly because, owing to its shape and limited size, of moderately advanced cases, and 68% of advanced cases.

It should be possible to carry out in Great Britain a programme similar to these in America, and in this respect the mobile X-ray unit and operating-theatre proposed by Dr. Hoffstaedt[3] would be invaluable. Collapse therapy could be instituted in the home after adhesion-section in those cases requiring it; and the patients could continue to be nursed there. Mobile mass miniature radiography units could be used to pick up the early cases.

The sanatorium physician must be prepared to accept cases that have had home treatment until the "early" cases, likely to respond to a sanatorium regimen, are the only ones claiming admission. Coöperation in carrying out the programme as outlined would soon lead to a decrease in the number of notifications of tuberculosis and ultimately to a fall in the death-rate.

Graduate School of Medicine,
University of Philadelphia.
KENNETH MARSH.

SIR,—Tuberculosis is by far the most serious disease affecting our community, but any campaign against it is liable to fail if physicians themselves do not agree on the methods to be adopted. In the present situation all possible means of obtaining treatment for patients should be employed, whether sanatorium or domiciliary. At a time when patients must wait anything from 8 to 12 months for a bed, sanatorium physicians should not demur at receiving them with some form of collapse therapy already in progress. In the long run the patient who has to wait a long time for admission gains by early collapse therapy in his own home, and it reduces the period he will need in sanatorium when admitted.

Little has been done, however, to organise domiciliary management, and meanwhile it appears that we are still fighting a losing battle. In December, 1944, in England and Wales, there were some 4000 cases awaiting admission to hospital; but by December, 1948, the waiting-list had risen to 9000, and I suspect that it will be over 10,000 by the end of this year. In the same period there has been little change in the number of beds available for tuberculous patients.

I see nothing for it but to bring tuberculosis back once more into the general hospitals where it belongs. In this way not only would the teaching of students in early diagnosis be greatly facilitated but the nursing of the cases would also be eased considerably. Is it not the isolation of the tuberculosis sanatoria, and the conception of the work as rather monotonous and lonely, that prevents more nurses taking up this type of service? Furthermore, beds in general hospitals, under the direct supervision of the chest-clinic physician and where a thoracic surgeon is available, can be used in conjunction with domiciliary management far more economically, and serve a far greater number of patients, than can the same number of beds in a sanatorium. The ever-to-be-desired aim of one physician looking after a case from diagnosis to rehabilitation can be achieved in this way as in no other. The over-all problem in a given district can never be appreciated by the sanatorium physician as fully as by the chest-clinic physician who watches the waiting-list and sees the many new cases diagnosed. In a sanatorium there will obviously be a tendency to keep cases longer than would be absolutely necessary were the sanatorium physician able to continue his treatment in the patient's own home.

Also there is a very natural feeling among experienced sanatorium physicians that domiciliary collapse therapy is dangerous, particularly when undertaken by physicians with inadequate training and facilities. To a certain extent of course this is true; but it is a sad reflection upon a system whereby physicians carrying out tuberculosis work in clinics have always been graded at a somewhat lower level than general physicians or torium physicians—a state of affairs which perpetuated if action is not taken to make the s the chest-clinic worker equivalent in grade and to that of other specialists. If clinics are staffed keen well-qualified and well-trained men, there is reason why the work done in them should not be every way comparable to that done in our better toria. Not only can it be so but it must be so; for are facing a crisis, though this has hitherto been lar disregarded not only by administrators but by members of our own profession.

It is time that the tuberculosis service ceased to considered of lower grade than other specialist servi Instead of a gain in efficiency under the N.H.S. we a fantastic dichotomy by which the key worker in chest clinic is responsible to two or even three mas while at the same time an unduly high proportion of workers has been denied consultant status. Furtherm when the Minister sets up an Advisory Committee Tuberculosis we find that no practising chest- physician is included in its members.

It has been said that the new allegiance of the clinic physician to the regional hospital board dimin his domiciliary interests, and that he may there neglect the public-health side of this important "soc disease. Actually there has never been so m domiciliary visiting and such a keen interest in the so background of the tuberculous patients as is now evid But if we are to continue to tackle the greatest prob facing British medicine in the present desultory fas it may well be that a catastrophic rise in the incidence mortality in tuberculosis will occur. This is made the more possible by our becoming an ever susceptible nation, as indicated by the fact that 60% of school leavers in the Greater London area now Mantoux-negative. When this is considered ag the background of our acute housing shortage and consequent forced contact of susceptible youngsters infectious cases it is no longer surprising that we in our present position. Drastic national action Governmental level is urgently required—if necessary the expense of the care of other diseases of less importa to the community.

PETER STRADLING
Chest Physician and Lecturer in Tubercul
Postgraduate Medical School of London.
Hammersmith Chest Clinic, London, W.12.

SIR,—The aim of this letter is twofold: to try enlist the help of the school medical services in detec tuberculosis in school leavers, 16–18 years of age, to urge intelligent coördination of tuberculin testing and radiography for these young people. text, I take a girl and a boy recently admitted to sanatorium with advanced tuberculosis, neither of th known contacts.

The girl had a routine examination at the beginning of year in the VIth form, and no check-up to discover wh her cough and fatigue in the summer term were due solely examination stress. She left, and undertook library but as it was for a year only and not as a permanen no medical examination was required—since, ironic seems to be the superannuation purse that really The boy, who attributed his weariness to the burden of head boy at his boarding-school, had no routine examination, and his illness was only discovered when a radiography unit visited the factory where he was w in his college vacation.

School doctors may well have excellent (other than that of detecting tuberculosis) for their final examination at the beginning rather at the end of the VIth form year. But would it not possible to arrange that before the boys and girl to the greater freedom and more limited supervision work or student-life, they should all be tuber tested, and that the positive reactors, only, be X-ra ot think it would impose an impossible burden school doctors. To skin-test a batch of people a very formidable or lengthy business, and it ot actually be done by a doctor though perhaps she should read the result. The task of inter- the films of the positive reactors would not fall school doctor.

---

[3] Hoffstaedt, E. G. W. *Lancet*, Oct. 8, p. 672.

ay be argued that it would be better to X-ray leavers "just to make sure"; but this would belittle the value of the Mantoux test, and to attention from the need for X-ray examination antoux-conversion takes place. Everyone work- tuberculosis must be sadly familiar with the false f security engendered by the single X ray, taken nths or a year before, which was "all right," erefore led to disastrous delay in seeking advice symptoms arose. It is true that a misleading e reading may be found while allergy is develop- r because the patient has measles or miliary ulosis; but there are snags with any routine test. formidable part of the business would be in keeping with and re-testing the negative reactors after ave left school, and have become so very elusive. e might take heart from the satisfactory change in blic mind towards diphtheria inoculation, and hope his aspect of the campaign against tuberculosis lso be generally accepted. Skin-testing is less to create a tuberculosis-phobia than resort to ed "blind" X-ray examinations. In any case, is to come into its own in this country, extensive ux-testing will have to be done.

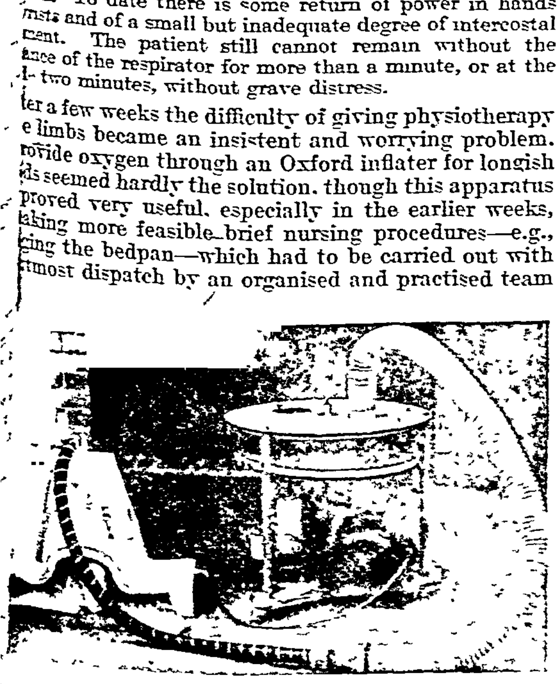
ell Hall Sanatorium, Sussex. RUTH DINGLEY.

IMPROVISED MECHANICAL RESPIRATOR

—The following account of an improvisation to protracted treatment and nursing in a box-type nical respirator may be of interest.

irl, aged 14, was admitted to the Coventry Isolation tal on June 18, 1949, with acute anterior poliomyelitis ing all the limbs and the back. Next morning the sis had spread to all the muscles except those supplied cranial nerves and the flexors of the fingers. Respira- diaphragmatic and intercostal, was grossly impaired apidly became virtually non-existent. The patient was l in a Both (Nuffield) box-type respirator and remains still. To date there is some return of power in hands rists and of a small but inadequate degree of intercostal ment. The patient still cannot remain without the ance of the respirator for more than a minute, or at the two minutes, without grave distress.

ter a few weeks the difficulty of giving physiotherapy e limbs became an insistent and worrying problem. rovide oxygen through an Oxford inflater for longish ds seemed hardly the solution, though this apparatus proved very useful, especially in the earlier weeks, aking more feasible brief nursing procedures—e.g., ing the bedpan—which had to be carried out with most dispatch by an organised and practised team of nurses and doctors. On the other hand, to transfer the patient wholly from her safe and life-saving Both respirator to some other type of respirator, which might leave the limbs accessible, was much too risky. Even if one could get such a respirator applied in time, which was very doubtful, it was uncertain whether the patient would tolerate it.



With this problem in mind, and having read Dr. Ursula Blackwell's article in *The Lancet* of July 16, 1949 (p. 99), the patient's father, who is connected with the Coventry engineering industry, and one of us (J. F. G.) visited the Western Hospital, Fulham, where they were kindly allowed to inspect the hospital's comprehensive collection of mechanical respirators. In particular from their Stille respirator we acquired the basic idea of a rigid suction chamber sealing over the patient's trunk, and we noted how the Stille shield had been adapted by the hospital staff with a Both motor and bellows unit. The father then set to work, with the help of a firm of pattern-makers, to construct a wooden mechanical respirator that would (1) fit over the chest and upper half of the abdomen only; (2) leave the limbs free; (3) fit over the respirator mattress so that the patient, having been drawn out, could yet remain secure in the Both respirator attachments, and if anything went amiss, could be promptly sealed up again in the box respirator in a matter of seconds; and (4) work off the box-respirator motor and bellows unit. A rubber valve and manometer similar to the Both were also planned to be fitted.

The sealing of the respirator round the patient to make an adequately airtight junction was the greatest single difficulty. It was solved by two devices: (1) The new respirator was made to measure, both to the patient and to the Both respirator mattress. Malleable lead strips were quickly moulded round the upper part of the chest, the axillæ, and the middle of the abdomen to obtain the relevant silhouettes. (2) A thick layer of 'Sorbo' rubber was fixed to those margins of the respirator which fit on to the patient. The sorbo was found to be appreciably porous to air, so, to overcome this, thin rubber aprons were fitted to the inside of the new respirator and carried round the sorbo. The free edge of this rubber sheeting, when tucked round the patient, assisted the sealing. This seal was completed by several pads of cotton-wool and (underneath) by the sorbo mattress supplied with the box respirator. The rubber bedpan, on which the patient lies, is removed when the patient is in the new respirator. To ensure that the respirator worked, and to make adjustments, experiments were made with a volunteer about the same size as the patient.

The respirator (see figure) is used daily for about twenty minutes, during which period the patient has massage and passive movements. The longest time the new respirator has so far been in use is half an hour, but there seems to be no reason why it should not remain on for very much longer, given full psychological tolerance. Unfortunately, this is not yet forthcoming, partly because the patient feels safer in her box respirator, and partly because she associates the new respirator with a degree of pain and discomfort inseparable at present from her passive movements. There is also a sensation of pressure across the abdomen when the respirator is working efficiently, especially during the phase of greatest suction.

The new respirator can be applied effectively in a few seconds by a minimum of four persons, but the patient must be lying squarely and centrally on her sorbo mattress, and the operators improve with practice. Of the four persons, two handle the respirator, one manages the arms, and the fourth attends to the hose and bellows. The respirator works well, but rather more suction is needed (18–20 cm. of water) to maintain the patient's colour than in the box respirator (14 cm. of water), possibly because, owing to its shape and limited size, chest and abdominal movements are less comprehensive in the new respirator. It is important for the patient not to have a full stomach when the new respirator is applied; omission to take this precaution seems to lead to cyanosis and nausea. Presumably in the patient's prone position the stomach lies high and is forced upwards against the diaphragm by the closely fitting respirator.

Unless enough spontaneous respiration returns in the near future to make mechanical aid unnecessary, our ultimate aim is to wean the patient from the box respirator into the new respirator. Once this stage was reached she could be transferred to a bed suitably adapted, and this would be a great encouragement to her.

It remains to praise the parents' resource and perfect coöperation, and to say that nothing could have been achieved without the constant assistance of Miss H. O'Sullivan, the sister in charge of the ward, the night sister, and all the other nurses who have handled the patient.

J. F. GALPINE
J. W. BROWN.

Coventry Isolation Hospital.

MEDICAL BIOPSIES

SIR,—In your annotation of Nov. 19 Dr. Bodley Scott is quoted as saying that aspiration biopsy of lymph-nodes "will avoid the full operative panoply which surgeons deem necessary for excision of the smallest and most superficial lymph-node." The reader must assume that you have quoted correctly, and I am afraid that the tone of Dr. Bodley Scott's statement, coupled with his eminence as a physician, may lead some of the younger surgeons—or even a rash young physician, if such a contradiction exists—to proceed to the removal of a lymph-node without appreciating the possible danger to the patient. Surgeons are only too apt to remove nodes before hæmatological and serological examinations have been completed, but speaking as a pathologist who has seen what can happen, I would commend wholeheartedly the surgeon who approaches this operation seriously and with every precaution taken.

It is no doubt Dr. Bodley Scott's misfortune to have a jesting remark, probably made with a smile at some surgical friend, quoted as if it were a considered opinion. Indeed, his interest in needle biopsy is certainly due to his full appreciation of the seriousness of this sometimes too lightly undertaken operation.

A. C. LENDRUM.

Dundee.

IRON POISONING

SIR,—May I offer a footnote to your leading article of Nov. 12 about iron poisoning? To avoid further tragedies, it is necessary that not only the patient who handles the tablets, but also the doctor who prescribes them, should be aware of the danger. The manufacturers of the proprietary ferrous sulphate tablets ('Fersolate') taken in the New Malden case print a warning on the container, but there is no such warning on the container in which the pharmacist issues the tablets on prescription. In this case the practitioner was consulted within five minutes and again after an hour and a half, and said that there was no danger and that the infant would be all right. Replying to questions at the inquest about the need for more attention, he said "If, as I thought, the tablets had contained no more than ferrous sulphate, it would not have been necessary." The pathologist said that previous fatalities had occurred from ferrous sulphate, but this was "perhaps not generally known." The coroner summed up, naturally, that "iron and iron sulphate were not generally regarded as poisons; it was not generally known, even perhaps among doctors, that fatal poisoning could occur." If this is so, more inquests seem probable.

HENRY PORTER.

THE DOCTOR'S CREED

SIR,—May I, as theological student and doctor,
out the weakness of Professor Platt's position
cannot accept the Christian creed, because God to
evil.

Is this not analogous to the situation of a s
presented with signs and symptoms suggesting a
citis? According to how these add up, he will ope
he will not. If he operates he sees for himself
does not, the death of the patient may also tell hi
could escape the issue by saying "As I do not kn
this patient has appendicitis, I will not operate
he would still be unable to escape the effects
decision.

Either God exists or He does not. He claims
revealed Himself in Nature, in the Old and New
ment, and in the person of Jesus Christ. A s
these three leads us to believe that God and C
exist. As in the case of appendicitis we can
absolutely sure, but there is sufficient evidence
us to believe, just as the evidence before the su
sufficient to lead him to operate.

If we believe, then our own lives must change,
our words and example we shall influence others.
not be too late to build a world in which Love,
and Brotherly Kindness predominate. If we
believe, what check is there, or need there be,
putting ourselves first and striving to further
by fair means or foul? "Life is short and we a
time dead." Since 1918 there has been a gradual
into practice of the latter formula—we see th
today.

As one who tries to be a Christian it is just here am most perplexed: for the Church seems to me h the reality of such miracles. and thus proposes compatible properties of God—omnipotence. ence. and benevolence—to which Professor Platt ost scientists object.

heologians and scientists could meet each other metaphysical field, they might find it easier to r the Archbishop of Canterbury's plea to work er and understand one another in the ethical and al fields in which their coöperation would be so tial.

rn, Penarth, Glam. C. M. FLETCHER.

—When, after years of labour and anxiety, we are to that upper room to receive our diploma, do we scribe to that Oath of Hippocrates, born in Cos 460 B.C.? Surely our standard of professional ct and our relation to our fellow men was laid before Christ, Mahomet, or Buddha.

fessor Platt has been brave enough to propound edo. I venture to advise his critics to live and live.

rne, Dorset. JOHN WHITTINGDALE.

—May I, very humbly, set out my working hesis?

ave rejected Christianity because of its geocentric cer. Contemplation of the stars in their courses s it impossible for me to believe that this is the planet on which life exists and that the Creator is ned only with the fate of man.

tribute to him infinite power, infinite intelligence, definite purpose. So far as this earth is concerned manifested in the evolution of a being whose mind s with the passage of the millennia and who becomes and more capable of dominating his environment. hat ultimate end I conceive there is no evidence.

the development of life on this planet the vegetable nimal kingdoms arose. The animals are divided into edators and the vegetarians, and a few of the larger mals—of which man is an outstanding example— g to both sections. Further, animals are either rious or solitary, man belonging to the former class. since he is omnivorous too, he is found to have in respect an almost unique position among higher mals. The predatory animal is selfish and ruthless. gregarious shows a greater or less amount of altruism. hypothesis is that in man there is conflict between the shness of the solitary flesh-eater and the altruism he gregarious, and that this clash between fundaal instincts is the reason for most of the world's resses. Flesh-eaters are not all solitary—witness wolves—but in the main I think the distinction is good.

e disposition of an individual depends on the balance inherited instincts and on his upbringing and later ronment. To the altruist—and that he may contly follow the Golden Rule is his highest aspiration ght and wrong are clearly differentiated and he feels me when he does not obey the dictates of his inherited tinct—conscience. To the predator right and wrong e different connotations and he simply does not erstand why the altruist should blame him and empt to circumscribe his liberty of action.

Is all this too simple to be true? It may well be so: t I derive from it a (to me) rational explanation of e present scheme of things. And so I reject with fessor Platt the conception of the benevolence of the eator and believe like the Preacher of old that Time d Chance happeneth to us all.

NESCIO.

SIR,—As doctors we all play a losing game, for ultimately death claims each patient. To relieve anguish of body and mind is the earnest desire of us all, but how infinitely better it is to relieve anguish of soul.

Having myself at one time greatly feared death, and having had that fear removed and replaced by an abiding peace of heart through coming to know Jesus Christ as my own personal Saviour, it has been a humbling and thrilling experience to be able to help men and women on their death-beds to find that same Saviour and to see peace reign where fear had held sway. Furthermore, having experienced defeat by sin in my life and having had that defeat changed to victory by the same Living Saviour, what a privilege it has been to help patients to find the same power through Christ.

I have numerous medical friends who have had similar personal experience to myself and who are similarly helping their patients to share it. What further proof need we of the goodness of God?

Wool, Dorset. T. B. L. BRYAN.

SIR,—One of your correspondents says that "Man may practise virtue or vice as he chooses. He may select deliberately (not by instinct) and follow any line of action from among many." Yet all the evidence patiently collected over the past seventy years or so goes to show that human conduct, far from being deliberately planned by a process of conscious reasoning, has its motivation very largely in the unconscious. We may explain away our behaviour very ingeniously by rationalisations which we have become adept at by long practice, but the true motives of our behaviour are rarely known to ourselves.

Glasgow. L. N. COOK.

SIR,—After the prominence you gave the Archbishop of Canterbury's speech I have rejoiced in Professor Platt's reply, because even today it requires considerable moral courage to state views contrary to accepted religious dogmas. Beyond that courage, the prerogative of intellectual leaders, it also showed Professor Platt to be a man of universal sympathy and comprehension.

Of the other letters Dr. Crichton-Miller's rightly emphasised the division which should exist between the priceless, ageless wisdom which found expression in religious literature and which is part of our cultural heritage, and the dogma itself, formulated by the desire to penetrate and placate the unknown, by fear and by ignorance.

Our world today is so eminently man-made that, although we were not the original creators of it, our first duty ought to be to be responsible for it. For education in general our aim ought to be to create individual and collective responsibility, not to shelve it. The cheerful acceptance of 6 million dead for some supposed sin that we don't know of, but which God has explained, may not prevent one from being a good Christian; but it most certainly bars one from responsible citizenship.

As for the cultural and moral gems which abound in religious literature, I believe it should be read, taught and enjoyed as other works of art at an age when credulity and the desire for literal truths has been tempered by a grain of experience, and then let everyone take as much as he can comprehend or digest. Then these two worlds would rightly have nothing to fear from one another.

Romford. H. SYMONDS.

SIR,—The query from Olim is answered by St. Paul in Romans 8. 18–25. Human suffering is there seen as an epitome of the suffering of all created beings and the redemption of the former holds out hope for the redemption of the latter.

Liverpool. CREDO.

SIR,—Most of the letters in reply to Professor Platt's admirably clear and balanced one of Nov. 5 are examples of the foggy thinking which some members of a scientific profession allow themselves when dealing with a non-scientific subject. One, for instance, doubts the possibility of considering as criminals the doctors who took part in the degrading bestialities of Auschwitz and Buchenwald. "What is right and what is wrong?" he asks. Surely even the Hippocratic Oath might give him, as a doctor, some clue. (It is unlucky for him that Hippocrates was a pagan: not a hope of proving his "Christian inheritance.") Others appear to feel that God is to be applauded for allowing man to exercise free will at Auschwitz and Buchenwald: if free will involves inflicting torture, that is just too bad; the principle is all that matters. Another remarks that if he cannot believe that God is "omniscient, omnipotent, and wholly benevolent," then Professor Platt must be an atheist.

And so it goes on: letter after letter, praising the spiritual value of suffering, and the importance of evil (without which "Christianity would be totally unnecessary"). The whole horrifying correspondence seems to me to have one merit: it is an excellent argument for atheism.

Edgbaston, Birmingham. CONSTANCE BACHTIN.

SIR,—May I reply to Professor Platt and at the same time gently chide my Christian colleagues who think that Christianity is the sole repository of the knowledge of God and of the forces arrayed against the evil of this world? The idea of the omniscience and omnipotence of God is derived from Abraham, who postulated Him as the creator of the universe. It was Moses who emphasised that man is endowed with free will to choose between good and evil, and moreover that good was rewarded and evil punished! Hitler chose Buchenwald and Auschwitz, and many "Christian" Germans chose to carry out his bestial wishes. The "divine" purpose behind this unparalleled exhibition of wickedness is to demonstrate that Christianity has not civilised the Germans and that greater efforts are still needed to civilise man and raise him from the level of the animal. The people who died in the gas-chambers were martyrs who should stir the conscience of every decent individual. The children who die of leukæmia and nephritis stir the conscience of doctors to whom is given the honour of eradicating their martyrdom. When I was a student, I saw patients die of pernicious anæmia until Minot and Murphy discovered the efficacy of liver extract. And so we look forward to the discovery of the cure for cancer and the other at present incurable diseases. No-one knows why the whole of knowledge was not given to us at once, but we can recognise right strivings from wrong and join with our agnostic friends who derive their hope and help from other directions, to achieve happiness for mankind.

Hull. L. I. HARDY.

SIR,—At times, especially recently, I have felt inclined to doubt the mission of our profession; it has seemed that we are all at sixes and sevens, with our eyes fixed only on the main chance. The correspondence in your journal, inspired by the Primate's message to Birmingham medical students and Professor Platt's comment on this, has resolved such doubts and I now feel that I can boast again that I am a citizen of no mean city. May we have "The Doctor's Creed" reprinted in toto, for surely it marks a very great occasion. It must be the first time that the medical profession have spoken with such unanimity, and it cannot be mere chance that this startling profession of faith comes just at a time when the discord among theologians is being so painfully revealed in a similar correspondence in the *Times*.

QUESTION TIME

How much are we Eating?

In answering questions Mr. JOHN STRACHEY, Minis
Food, said that for the whole of 1949 it was estimated th
per-capita consumption of fats, eggs, cheese, milk, te
bacon expressed as a percentage of pre-war consumption
be as follows: fats 98%, eggs 91%, cheese 110%,
49%, tea 87%; liquid milk 157%. These figures d
include the recent increases in the tea and bacon r
The latest calorie figure available—for the year end
June—was 2980 calories per head of the population p
which was not significantly different from the pre-war
of 3000 calories per head per day. The figures for the
rate of consumption, when they became available, mig
prove to be a significant number of calories abo
pre-war figure.

Research into Rheumatic Diseases

Colonel M. STODDART-SCOTT asked the Lord Presi
the Council what medical research was being done
Medical Research Council into the problem of the trea
cure, prevention, and cause of rheumatism, which affe
most 2 million of our people; and if he would state the
employed and the money expended yearly on this rese
Mr. H. MORRISON replied: The Medical Research
has a research unit which is at present wholly devoted
study of acute rheumatism, and they are making sub
grants for the support of research on rheumatic dis
various hospitals. In addition, they support much
fundamental problems of endocrinology such as led in
to the discovery of Compound E ('Cortisone'). The
expenditure by the council on these and allied proble
increased greatly since 1948 as a result of the new a
to the problem made possible by this discovery. E
ture by the council on research limited to rheumati
£1135 in 1946–47, £3800 in 1947–48, and £4810 in 19

Reduction of Doctors' Lists

Mr. JOHN RANKIN asked the Secretary of State for S
what steps he proposed to take to reduce the maximum
of patients on a doctor's list from 4000 to 3800 or some
smaller number.—Mr. ARTHUR WOODBURN replied:
arranging to explore this possibility with the profe
Scotland.

Shortage of Army Medical and Dental Offic

Mr. T. L. COLE asked the Secretary of State for W
was aware that the negligible entry into the Army of
and dental officers made it difficult to maintain a sati
standard of efficiency in those branches of the Service
steps were being taken to make conditions of servi
attractive; and if he would increase the present
emoluments received by medical and dental officers
Army, which compared unfavourably with those of
in the National Health Service.—Mr. MICHAEL S
replied: The present shortage of medical and dental
in the Army is well recognised. A joint investigati
the problem is being made by the three Service depa
with the Ministry of Defence.

Sickness Benefit

Sir WALDRON SMITHERS asked the Minister of
Insurance if the excessive resort to doctors in the
Health Service had been reflected in an excessive nu
claims for sickness benefit.—Mr. JAMES GRIFFITHS
Close comparison with the estimates in the Gove
Actuary's report on the Bill will not be possible until a
statistical material is available. Several special i
have, however, been made and the information a
gives me no reason to think that either the number or d
of claims to sickness benefit are in excess of what was e

Capitation Fees

Sir ERNEST GRAHAM-LITTLE asked the Minister of
if he was aware that the capitation grant varied
14*s*. 9*d*. and 17*s*. 10*d*. in different areas; and what w

for this variation.—Mr. ANEURIN BEVAN replied: pitation payments in executive-council areas vary ng to the amount of the local practitioner funds are proportionate to the number of persons on doctors' each area plus one-third of the number not on doctors' ere) and according to the first charges which are m these funds. The method of distribution has been with the medical profession.

Operation Hours

-Colonel D. L. LIPTON asked the Minister of Health m and in what hospitals orders had been issued limiting of operating-theatres to the hours 9 A.M. to 5.30 P.M.—VAN replied: I am making inquiries.[1]

-Colonel LIPTON: Does the Minister's reply mean rd Horder has not yet had the courtesy or the courage stantiate the allegation—(cries of "Order")—which absence of factual supporting evidence will be regarded sponsible and, possibly, even malicious? Mr. BEVAN: as I can make out—and I have made inquiries—we ceived no information whatsoever from Lord Horder before or since he made his statement.

SPEAKER said that the supplementary question was an on a member of the House of Lords and it should ve been made. It referred to a statement made in the nd there was no need in the question to mention any at all. Hon. Members: Withdraw. Mr. BEVAN, oint of order, said the statement was made by a member House of Lords but not in his capacity as a member House of Lords. Could a Noble Lord make any statehe liked in any other capacity and claim immunity? PEAKER: It was a very offensive supplementary on imputing malice and it is not in order for questions offensive.—Mr. BEVAN: Further to that point of order, ld point out to you, Mr. Speaker, that the original ent complained of was exceedingly offensive.

WILSON HARRIS: Is it so unreasonable that what may med routine operations should be confined to these provided that emergency operations can take place hour? Mr. BEVAN: There are many inquiries to make ere are thousands of hospitals. In the absence of any ular information I have now to circularise all the al management committees. Certainly, it is perfectly able for operating-theatres to be closed during certain if they are always available for emergency operations, e implication here is a reflection on the National Health e. Mr. HENRY STRAUSS: Was not the original answer ectly proper one that the Minister was making inquiries, it not premature to say now whether this is substantiated ? Mr. BEVAN: A responsible person, if he thought that as being done, would have written to the Minister and him the name of the hospital in order that he might inquiries. Instead of that much anxiety, pain, and have been unnecessarily given to many hundreds of ands of people.

Use of Penicillin

S. T. SWINGLER asked the Minister what instructions een made by his department or by any regional hospital d to any hospital to reduce the use of penicillin on the d of expense; and if he would give an assurance that the f drugs under the National Health Service lay entirely n the discretion of doctors.—Mr. BEVAN replied: No instruction has been issued either by me or by any al hospital board and the matter is one entirely at the tion of the doctor. Mr. SWINGLER: Will the Minister request, very courteously, a member of the House of s either to substantiate or to have the common decency thdraw his allegation?—Mr. BEVAN: I do not propose nter into any communication with the noble Lord in this ter. If he will send me the precise information upon h he bases his very serious allegation, I will have inquiries le. In the absence of this information I can only ask the try to take no notice of such irresponsible statements.

Course for Trade-union Officers

r. CHARLES SMITH asked the Minister whether he had sidered the correspondence forwarded to him by the Member for Colchester indicating the refusal of a hosal management committee to grant special leave without pay to a member of the staff to attend a training course for trade-union officers; and whether, in view of the importance of building up a staff consultative machine in the hospital service, he would circularise all committees advising them to look sympathetically on such applications. Mr. BEVAN replied: Yes, Sir, and I am at present considering whether any more general advice to hospital management committees would be justified.

Mr. PHILIP PIRATIN: Can the Minister tell the House whether any guidance has been given to hospital boards in connexion with facilitating trade-union recruitment of the nurses and staffs? Mr. BEVAN: There is no need for me to give general guidance in this matter at all. All the arrangements for the recruiting of trade-union membership are well known to the unions concerned. Mr. SMITH: As hospital managements apparently do not recognise the desirability of setting up consultative machinery, and the necessity for this to be done by suitable people, who should be given an opportunity of having proper training for it, does the Minister really not think that some kind of indication from him is desirable on that point? Mr. BEVAN: As I said in my first answer, I am proposing to make inquiries to find out whether some general guidance ought to be given.

New Tax on Prescriptions

Sir THOMAS MOORE asked the Minister if he had made an estimate of the extent to which the proposed 1*s.* tax on National Health prescriptions would reduce the demand on doctors or, alternatively, increase the demand on chemists.—Mr. BEVAN replied: No, Sir. There is evidence of unnecessary resort to doctors and chemists which the proposed charge is intended to reduce, but I am unable to estimate the exact extent to which this is likely to take place. There is no reason why the proposed charge should increase the demand on chemists.

Price of Drugs

Mr. PIRATIN asked the Minister whether, in view of the high prices charged for prescribed medicines and proprietary brands of medicines and with a view to saving Government expenditure, he would consider introducing measures to control the drug industry.—Mr. BEVAN replied: The prescribing of unnecessarily expensive drugs is being investigated by a joint committee of the Central and Scottish Health Services Councils and I am waiting for their report.

Psychotic Children in Mental Hospitals

Mr. V. J. COLLINS asked the Minister if he was aware that owing to lack of suitable accommodation a number of psychotic children were housed in the same wards as adult patients in mental hospitals within the South-Western hospital region; and if, in his plans for dealing with this problem, he would have due regard for the desirability of providing the necessary accommodation on a regional basis.—Mr. BEVAN replied: The South-Western regional hospital board have recently made a careful inquiry into the question of accommodation for child psychotics in their region and have been in consultation with my officers about it. I am informed that there are now only three psychotic children in mental hospitals in the region and efforts are being made to remove them to other accommodation. The answer to the second part of the question is "Yes." We do not consider it desirable to have these children in mental homes for adults.

Leprosy Treatment at Reigate

Mr. G. C. TOUCHE asked the Minister if he was aware that the use of the Reigate and Redhill Infectious Diseases Hospital for cases of leprosy would embarrass the Reigate borough council in the discharge of its statutory duties in connexion with the supervision and control of infectious diseases in the borough of Reigate unless adequate alternative hospital accommodation was provided; and if he would give an assurance that such accommodation would be available before the present isolation hospital was turned into a leper colony.—Mr. BEVAN replied: Adequate alternative accommodation for cases of infectious disease already exists in other isolation hospitals in the area.

Hospitals and Casualty Announcements

Mr. BARNETT JANNER asked the Minister whether he was aware that, following a bus accident in Twickenham recently which resulted in people being taken to the West Middlesex Hospital, the names of the injured were not released to the newspapers until more than two hours had elapsed after admission; and whether, in view of public anxiety over such accidents, he would ask all hospitals to give such information without delay.—Mr. BEVAN replied: Full particulars were given to press representatives within half an hour after the last casualty was admitted to hospital. Hospitals have already been asked to give particulars of accident casualties to the press as quickly as possible.

---

[1] The restriction of the use of operating-theatres and the prescribing of penicillin were mentioned by Lord Horder at the meeting of the Fellowship for Freedom in Medicine, on Nov. 19.

Replying to further questions Mr. Bevan said he thought it would be the view of everyone that it was desirable for relatives to hear of the accident first of all from the hospital and not read about it first in the press. He had no reason to suppose that the hospital had been at fault in any particular. Indeed there was every admiration for its administration.

Constituents of the National Loaf

Sir ERNEST GRAHAM-LITTLE asked the Minister of Food what were the present constituents in the national loaf, and in what proportions they were supplied; and what was the present subsidy in respect of bread as a single item.—Mr. JOHN STRACHEY replied: Not less than $87^1/_2\%$ of the flour used in national bread must be national flour. Substances other than national flour which may be included in national bread are:

Imported flour	Improvers of the nature of yeast food
Oils and fats	Any acid or acidic substances suitable for regulating the acidity of the dough
Water	
Salt	Potato and potato flour
Yeast	Barm

These materials are not supplied in any specified proportions but are obtained by bakers as required, subject only to a limitation as to the quantities of flour and oils and fats which may be purchased.

The total subsidy on bread, including the flour and baking subsidies, is estimated approximately £64·1 million per annum for the current financial year, of which £8·4 million represents the subsidy payable to bakers. The total subsidy is equivalent to about 6*d.* on each $3^1/_2$ lb. loaf.

Public Health

Water Softening

A Ministry of Health committee whose report[1] has appeared this week advises eventual extension of central water-softening schemes to all hard-water areas; and the committee has found no evidence that either hard or soft water is prejudicial to health. With some exceptions, central water softening is unlikely to benefit productive industry. Implementation of softening schemes will have to be deferred until economic conditions improve; and at present money, labour, and materials available for the water industry should be devoted to ensuring that water is sufficient.

Poliomyelitis

During the week ended Nov. 19, notifications in England and Wales were: poliomyelitis 219 (293), polioencephalitis 7 (23). Figures for the previous week are shown in parentheses. The decline in incidence has been greater than in the previous week. Multiple cases were reported from the following counties:

London 19 (47), Bedford 3 (1), Berkshire 5 (6), Buckingham 3 (3), Cornwall 2 (3), Cumberland 3 (1), Durham 2 (1), Essex 14 (18), Gloucester 8 (8), Hertford 4 (4), Kent 20 (22), Lancaster 10 (24), Leicester 3 (6), Lincs, Lindsey 2 (8), Middlesex 15 (15), Norfolk 3 (6), Northumberland 4 (6), Nottingham 4 (2), Somerset 4 (4), Southampton 3 (9), Stafford 2 (3), Suffolk, East 2 (1), Surrey 6 (14), Sussex, East 4 (8), Warwick 13 (6), Yorks, West Riding 32 (42), Glamorgan 10 (5), Monmouth 2 (1).

Typhoid Fever at Salford

Up till Nov. 26 there had been 28 confirmed cases and 6 cases not yet fully confirmed of infection with *Salmonella typhi* following meals taken at the Masonic Hall, Salford, before Nov. 7. There has been no death.

His monograph *Malaria in Bombay City*, which is lassic, showed the unexpected way in which a great a million inhabitants permeated with malaria be freed from the disease, as was indeed later d. As director of public health with the govern- f Bengal he worked strenuously at another great problem—the control of malaria in the region of ing rivers of Bengal. On his retirement from in India he was appointed to the chair of hygiene Egyptian University at Cairo, which he held till After returning to England he acted as medical of the child-welfare clinics at Wallington, Surrey, he spent his retirement.

ything Bentley undertook he carried out with ling enthusiasm and he never spared himself. A writer, he published many papers and reports as r of public health, of which *Malaria in Bengal* and *Malaria and Agriculture* (1925) were out- g. "To his friends," S. R. C. adds, "he was a ing and interesting companion and colleague. erate and understanding, he showed a generous nd of trouble to himself when doing kindnesses rs. He had brought the same qualities to his work. an intense interest in the problems and troubles Indian coolies or villagers, so that he was persona and in his element among them."

916 he received the Kaisar-i-Hind gold medal, and s appointed C.I.E. in 1929. In 1931 the University cutta conferred on him the honorary degree of M.D. s retirement from his Egyptian chair he was made ander of the Order of the Nile. He leaves a widow, ns, and two daughters.

Appointments

L. P. L., L.R.C.P.I., F.R.C.S.E., D.L.O.: ear, nose, and throat geon, north-west group of hospitals, Londonderry area.

l Service:

N, W. A., M.R.C.S.: senior M.O., Nyasaland.

ER, J. K., M.B. Glasg., D.P.H., D.T.M. & H.: senior M.O., Uganda.

AULEY, M. L., B.A., M.B. Dubl.: senior M.O., Fiji.

KICHAN, I. W., M.B. Camb., D.T.M. & H.: senior M.O., Uganda.

ERSON, D. R., M.B., B.SC. Glasg., D.T.M. & H., D.M.R.E.: specialist radiologist, superscale grade B, Federation of Malaya.

CEY, J. R. P., M.R.C.S.: M.O., Nigeria.

NELL, R. H., M.B. Lond., F.R.C.S.E.: surgeon specialist, Zanzibar.

EMOND, WILLIAM, M.B. Glasg.: M.O., silicosis bureau, Northern Rhodesia.

IES, H. G. H., B.A., B.M. Oxfd, D.T.M. & H.: senior M.O., Kenya.

INS, VIOLET, M.B. Edin.: lady M.O., Nigeria.

SON, W. A., M.D. Lond., D.P.H., D.T.M. & H.: senior M.O., Uganda.

Births, Marriages, and Deaths

BIRTHS

EDN.—On Nov. 15, in Manchester, the wife of Dr. C. Fridjhon —a daughter.

EST.—On Nov. 21, at Windsor, the wife of Mr. A. M. Gilchrist, R.C.S.—a son.

AMORE.—On Nov. 24, at Stapleford, Notts, the wife of Dr. T. O. damore—a daughter.

MARRIAGES

INS—EDGAR.—On Nov. 22, in London, Bethel Eric Robert mons, M.D., to Gillian Evaline Ruth Edgar.

—MITCHELL.—On Nov. 26, in London, R. F. Stubbs, M.B., Mrs. F. R. Mitchell.

DEATHS

SON.—On Nov. 25, in Manchester, James Henry Albinson, M.B. Manc.

TLEY.—On Nov. 23, at Carshalton, Charles Albert Bentley, C.I.E., M.B. Edin., D.P.H., D.T.M. & H.

WN.—On Nov. 20, Francis Joseph Brown, M.R.C.S., lieut.-colonel, R.A.M.C. retd, aged 83.

KIERNAN.—On Nov. 21, at Falmouth, Thomas Hugh Robinson McKiernan, B.A., M.B. Dubl.

OOD.—On Nov. 23, Allan Edward Mahood, M.B. R.U.I., F.R.C.S., aged 86.

R.—On Nov. 28, in Edinburgh, John Orr, M.D. Edin., F.R.C.P.E.

RY.—On Nov. 19, at Caermenai, Caernarvon, William Hilton Parry, M.C., M.B. Lpool.

VE-FLAXMAN.—On Nov. 20, in London, Samuel Christopher Reeve-Flaxman, M.R.C.S., aged 69.

DERS.—On Nov. 20, at Four Oaks, Warwickshire, Arthur Addison Sanders, O.B.E., M.B. Birm., surgeon captain, R.N. retd.

REY.—On Nov. 24, Bryan Hamilton Storey, M.R.C.S., aged 27.

LIVAN.—On Nov. 23, at South Kirkby, Yorks, Edward James Holmes Sullivan, M.D. R.U.I., aged 90.

Notes and News

FIFTY YEARS OF TROPICAL MEDICINE AT LIVERPOOL

ON Nov. 22, when a gathering was held at the Liverpool School of Tropical Medicine to commemorate the 50th anniversary of its foundation, the Mary Kingsley medal was awarded to representatives of the families of those who had helped to found and to maintain the school, and also to scientists distinguished in the field of tropical medicine. These latter were Emeritus Prof. D. B. Blacklock, Prof. P. A. Buxton, F.R.S., Prof. N. Hamilton Fairley, F.R.S., Dr. A. F. Mahaffy, Sir Philip Manson-Bahr, Sir Edward Mellanby, F.R.S., Prof. Jerome Rodhain (Antwerp), Dr. Paul F. Russell (U.S.A.), Prof. H. E. Shortt, Brigadier J. A. Sinton, F.R.S., Prof. N. H. Swellengrebel (Amsterdam), and Prof. W. H Taliaferro (U.S.A.). The medal was also conferred posthumously on Warrington Yorke.

The origin of the school goes back to 1898 when Joseph Chamberlain, then Secretary of State for the Colonies, at the insistence of Sir Patrick Manson appealed to the country for the foundation of centres of study for tropical diseases able to undertake the training of doctors for service in the Colonial Empire. A number of commercial and medical interests in Liverpool met together on the initiative of Alfred Lewis Jones, who was then head of the Elder Dempster Line engaged in trading to West Africa. As a result the school began work in April, 1899, in the wards of the Liverpool Royal Southern Hospital, under the chairmanship of Alfred Jones, and with Rubert Boyce, professor of pathology in the then University College, as dean. One of the first members of the staff was Ronald Ross, who was appointed lecturer in tropical diseases. In 1905 a branch laboratory of the school was established at Manaos, on the Amazon, where research initially was concentrated on yellow fever. In 1921 a second laboratory was opened in Freetown, Sierra Leone, the funds being provided from a bequest by Sir Alfred Jones. Meanwhile the school had become integrated with the University of Liverpool, and some members of the staff were appointed to newly founded university chairs.

The activities of the school have steadily grown, and at present an enlarged staff is actively engaged in teaching and in research both in this country and overseas, and in the diagnosis and treatment of tropical diseases in this country. With half a century of substantial achievement behind it, including the work of men like Ross, Stephens, Warrington Yorke, Newstead, and Blacklock, there is every incentive to face the next half century with determination and confidence.

THE DISTINCTION AWARDS

IN our leading article of Oct. 22 we wrote of the Spens Committee's proposal "that after a specialist had reached his maximum basic salary of £2500 (now £2750), his remuneration should cease to depend in any way on the length of his service, but that distinction awards, of three different grades, should be made to 34% of specialists selected . . . as exceptionally meritorious." This sentence has, we understand, been taken to imply that distinction awards can be made only to consultants who have reached the maximum basic salary of £2750. We must therefore make it clear that no such implication was intended. The summary of the Spens Committee's recommendations says that "*all specialists of staff status* should be eligible for these distinction awards," and one of the committee's explicit objects was "to ensure that *in the lower age range also* outstanding ability should be rewarded by remuneration in excess of the basic incremental scale" [our italics].

University of Oxford

On Nov. 19 the degree of D.M. was conferred in absence on W. B. Matthews.

Scottish Conjoint Board

The following candidates, having passed the final examination, have been admitted to the licentiateship of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow:

A. R. Acton, D. J. M. Allan, Catherine Aicken, Eva M. Bobasch, Mary Brannigan, E. G. Caira, Catherine Coneghan, W. K. Davidson, D. G. Davies, W. A. Dryburgh, Esin Anwana Esin, M. M. Ferris, Elizabeth M. Fulton, J. C. Gallagher, T. C. Glasgow, Jean M. Greenwood, W. T. G. Hathaway, E. H. Jacobs, J. M. King, Marjorie J. Lyon, M. B. McElroy, John McGlone, Barbara P. P. Melhuish, A. J. R. Milner, S. H. Morgenstern, Joan M. Ponsford, Margaret J. Sutton, G. A. Taylor, R. L. Volinsky.

to the newspapers until more than two hours had elapsed after admission; and whether, in view of public anxiety over such accidents, he would ask all hospitals to give such information without delay.—Mr. **Bevan** replied: Full particulars were given to press representatives within half an hour after the last casualty was admitted to hospital. Hospitals have already been asked to give particulars of accident casualties to the press as quickly as possible.

Replying to further questions Mr. Bevan said he thought it would be the view of everyone that it was desirable for relatives to hear of the accident first of all from the hospital and not read about it first in the press. He had no reason to suppose that the hospital had been at fault in any particular. Indeed there was every admiration for its administration.

Constituents of the National Loaf

Sir **Ernest Graham-Little** asked the Minister of Food what were the present constituents in the national loaf, and in what proportions they were supplied; and what was the present subsidy in respect of bread as a single item.—Mr. **John Strachey** replied: Not less than 87½% of the flour used in national bread must be national flour. Substances other than national flour which may be included in national bread are:

Imported flour
Oils and fats
Water
Salt
Yeast

Improvers of the nature of yeast food
Any acid or acidic substances suitable for regulating the acidity of the dough
Potato and potato flour
Barm

These materials are not supplied in any specified proportions but are obtained by bakers as required, subject only to a limitation as to the quantities of flour and oils and fats which may be purchased.

The total subsidy on bread, including the flour and baking subsidies, is estimated approximately £64·1 million per annum for the current financial year, of which £8·4 million represents the subsidy payable to bakers. The total subsidy is equivalent to about 6*d.* on each 3½ lb. loaf.

Public Health

Water Softening

A Ministry of Health committee whose report[1] has appeared this week advises eventual extension of central water-softening schemes to all hard-water areas; and the committee has found no evidence that either hard or soft water is prejudicial to health. With some exceptions, central water softening is unlikely to benefit productive industry. Implementation of softening schemes will have to be deferred until economic conditions improve; and at present money, labour, and materials available for the water industry should be devoted to ensuring that water is sufficient.

Poliomyelitis

During the week ended Nov. 19, notifications in England and Wales were: poliomyelitis 219 (293), polioencephalitis 7 (23). Figures for the previous week are shown in parentheses. The decline in incidence has been greater than in the previous week. Multiple cases were reported from the following counties:

London 19 (47), Bedford 3 (1), Berkshire 5 (6), Buckingham 3 (3), Cornwall 2 (3), Cumberland 3 (1), Durham 2 (1), Essex 14 (18), Gloucester 8 (8), Hertford 4 (4), Kent 20 (22), Lancaster 10 (24), Leicester 3 (6), Lincs, Lindsey 2 (8), Middlesex 15 (15), Norfolk 3 (6), Northumberland 4 (6), Nottingham 4 (2), Somerset 4 (4), Southampton 3 (9), Stafford 2 (3), Suffolk, East 2 (1), Surrey 6 (14), Sussex, East 4 (8), Warwick 13 (6), Yorks, West Riding 32 (42), Glamorgan 10 (5), Monmouth 2 (1).

Typhoid Fever at Salford

Up till Nov. 26 there had been 28 confirmed cases and 6 cases not yet fully confirmed of infection with *Salmonella typhi* following meals taken at the Masonic Hall, Salford, before Nov. 7. There has been no death.

SURVEY OF PHYSICAL FITNESS IN CEYLON

H. CULLUMBINE
M.D., M.Sc. Sheff.
SOR OF PHYSIOLOGY AND PHARMACOLOGY IN THE UNIVERSITY OF CEYLON, COLOMBO

term "physical fitness" has a different meaning ferent people, but to the physiologist it implies the ability to perform muscular effort. Gallagher rouha (1943) have indicated at least three main of physical fitness: (1) *static fitness*, as shown by ganically sound and well-developed body: (2) *ic fitness*, the ability to perform muscular effort;) *specialised fitness*, the ability to perform particular

assessment of specialised fitness lies at present in the field of the physiological psychologist, is the pure physiologist has concerned himself he study of dynamic fitness. There are many tions, however, that dynamic fitness is significantly iced by static fitness (Seltzer 1940, Gallagher and a 1943, Cullumbine et al. 1949b).

re are many different types of muscular effort; there must be many aspects of dynamic fitness. lly the ability to perform different muscular efforts ds on the possession of some or all of the following rties: ability for moderate exercise; ability for exercise; ability for protracted moderate exer-speed; and strength. Each of these five properties therefore be assessed in a comprehensive appraisal namic fitness.

assessment of dynamic fitness rests on the fact that are measurable differences in performance and in logical response to exercise between the fit and nfit. Thus, if we compare fit and unfit men of the height and weight, doing the same amount of rate work, we find that the fit man has a lower n consumption, a slower pulse, a lower systolic -pressure, a lower blood-lactate level, and a larger volume while working, and a faster return of the pressure and the pulse-rate to resting values after (Bock et al. 1928). If both the fit and the unfit perform severe work, the fit man can continue for a time before he is exhausted and has a higher n consumption, a lower maximal pulse-rate, a larger e volume, a higher blood-lactate level, and a er return of his blood-pressure to normal after work inson and Harmon 1941). Thus, the difference in ological response between the fit and the unfit s with the severity of the exercise, so tests of ise performance should include those involving rate effort and those involving effort to exhaustion. e physiological criteria used for judging exercise rmance are those enumerated above for distinguish-etween the fit and the unfit. Not all those criteria, wer, are equally sensitive or equally valuable. Most ers agree that the pulse-rate during recovery and lood-lactate level are the most sensitive measures of ss for moderate exercise, and that the time for which ise can be maintained is the best index of fitness in ular effort to exhaustion. Therefore fitness indices, d on the pulse-rate during recovery and the time of ormance of the test exercises, are usually used to give merical quantitative assessment of a person's response xercise (Johnson et al. 1941). We have also shown the systolic blood-pressure during recovery can be in calculating similar fitness indices (Cullumbine 9a).

TESTS

or our exercise tests we used a step 20 inches high, subject stepping up and down from this step at a constant rate, timed with a metronome. The step test was chosen because it has the advantage for field work of needing little apparatus and little skill to perform. It involves a natural type of exercise, performed at a constant rate and involving large groups of muscles and it places the cardiovascular and respiratory systems under definite stress. Various modifications of the step test have been used to assess the different aspects of dynamic fitness. Thus, the following functional tests have been performed by each subject:

(1) The Harvard step test (Brouha et al. 1943), which is a moderate exercise test in which a "steady state" in cardiovascular and respiratory response is reached (Cogswell et al. 1946). Thirty "step-up and step-down" cycles a minute were performed for 5 minutes, and the fitness index (pulse) and the fitness index (blood-pressure) were calculated for each person. This test has been shown to be a rapid and reasonably accurate method of assessing exercise fitness (Gallagher and Brouha 1943), and we have shown that it will distinguish between groups of people known to possess different types of fitness, and that reproducible results can be obtained with it.

(2) The endurance step test (Cullumbine 1949a), which is a severe exercise test in which a rapidly increasing oxygen debt is acquired and fatigue quickly ensures. Here forty-five cycles a minute were performed until the pace could be maintained no longer, and the endurance index (time), endurance index (pulse), and endurance index (blood-pressure) were obtained for each subject. We have shown that this test distinguishes the fit from the unfit, gives repeatable assessments in the case of people not undergoing specialised training, and, for trained athletes, can differentiate between those specialising in long-distance running and those specialising in shorter distances.

(3) The exhaustion step test measures ability to sustain moderate effort to fatigue, thirty cycles a minute being performed for as long as possible. The exhaustion index (time), the exhaustion index (pulse), and the exhaustion index (blood-pressure) were calculated for each subject.

(4) Speed of movement was simply assessed by the time required to run competitively 100 yards.

(5) Strength was measured by the ability to lift a graded series of weights 20 inches from the ground. The grip of the right hand was also measured with a dynamometer. These strength tests will note increases produced by training (Cullumbine 1949a).

Motivation is very important in all performance tests, especially those involving effort to fatigue. For this reason the subjects tested usually performed the endurance step test with the vocal support of their colleagues, whereas the exhaustion step test was made a competition between rival schools. Similarly, all our measurements of speed were made during competitive running.

Our survey has so far included about 8000 subjects, from the age of 10 years upwards and of either sex, of the Sinhalese, Ceylon Tamil, Indian Tamil, Moorish, and Malay races, and of burgher extraction (chiefly Dutch burghers claiming descent from the Dutch colonists). Most of them were school-children, but the adults included workers on tea, rubber, and coconut estates, harbour labourers, government clerks, members of the Agricultural Corps, policemen, plumbago miners, and, in a few instances, entire village communities. The subjects were picked at random, so far as possible, from those said to be typical of the racial, social, and economic status of each province.

All the subjects were examined in their native environment. Up-country and low-country districts, cities, towns, and villages, wet and dry zones, and malarial and healthy areas were visited. Only accessibility by track or by moderate distances of porterage limited our choice. The same team surveyed the whole island, and each person was in charge of the same tests throughout.

Measurements were made of exercise-performance ability, of vital capacity, of various anthropometric diameters, circumferences, and lengths, and of the greatest circumferences of the arm, forearm, thigh, and

Paddington Green Hospital

The board of governors of St. Mary's Hospital, London, decided, at a meeting on Nov. 24, to ask the subcommittee on reorganisation and coördination of services to reconsider their original proposals with a view to formulating a revised scheme which would provide for the retention of Paddington Green Hospital as a children's hospital.

Training of Psychiatric Registrars

The North East Metropolitan regional hospital board have approved a scheme to enable registrars in psychiatry to prepare for the diploma in psychological medicine. Training in clinical psychiatry will be carried out in the board's own hospitals; and opportunity will be provided for trainees to obtain additional instruction at the Maudsley Hospital, Denmark Hill, and at the Maida Vale Hospital for Nervous Diseases. The course, lasting three years, will include all branches of psychiatry and ancillary subjects. Trainees will be able to attend selected child psychiatric clinics of teaching standard. Arrangements will also be made for the secondment of students to a mental-deficiency institution, or, in the case of trainees working in mental-deficiency institutions, to a mental hospital.

Society of Medical Officers of Health

At this society's annual dinner in London on Nov. 24, Sir Wilson Jameson heard warm tributes to his work as chief medical officer to the Ministry of Health—a post from which he is to retire next May. Prof. R. H. Parry said that medical officers of health felt "an especial admiration for him, and it is not only the circulars he sends us"; while Prof. Hilda Lloyd, president of the Royal College of Obstetricians and Gynæcologists, spoke with pleasure of the honorary fellowship of the college which he had received. Mr. Aneurin Bevan described him as "one of the very great public servants of Great Britain." Mr. Bevan had learned by experience that usually the greater a man's academic qualifications, the more remote he was from *reality*. But in Sir Wilson Jameson knowledge was matched by sagacity; he was one of the wisest men, and he was also extraordinarily amiable.

Mr. Bevan, who was proposing the Society, pointed out that Sir Wilson, and also his successor, were former medical officers of health. He himself had spent seven years on a county council, where he had learned greatly to respect medical officers of health. In moments of candour he told clinicians that by and large the largest contributions had been made by the medical officer of health and the sanitary inspector; but he did not wish to pursue this subject, which might lead him to one or two topics that he was anxious to avoid. He believed that the past four and a half years had been the most fertile in the history of public health in Britain. Some found difficulty in reconciling themselves to change; but "I believe that as the years go by people will begin to wonder what they did without the health service." He fancied that the medical profession's first gleeful anticipation of being rid of him was being replaced by a dawning apprehension. Was it perhaps that the profession preferred the devil it knew, or had it become masochistic? There might even be a sense of nostalgia at his departure, and he looked forward to the time when the B.M.A. would send a round-robin to the Prime Minister of the day appealing for his recall to the Ministry of Health.

In reply, Dr. H. C. Maurice Williams, the president, spoke ruefully of the small number of candidates for the D.P.H. and for posts in public health. It was the public-health officers who had appreciated the value of a comprehensive—and indeed of a full-time—medical service. Yet in the service preventive medicine took second place to curative medicine. "If we had had the wisdom to establish a Royal College of Preventive Medicine, we should have found ourselves in a much better position." Though some advocated regionalisation, he personally hoped that public health would continue to be associated with local authorities, whose influence he had found stimulating. He hoped, too, that health centres would be instituted as quickly as possible, even in improvised buildings. Both Mr. Bevan and Sir Stafford Cripps were constantly in the thoughts of the medical officer of health—Mr. Bevan as the architect of the future structure, and Sir Stafford because of a sentiment aptly expressed in *Chronicles*: "Behold, I say, how they reward us."

Professor Lloyd and Lord Kennet responded to the toast of The Guests proposed by Professor Parry, the immediate past-president.

King Edward VII College, Singapore

Dr. E. S. Monteiro has been appointed to the clinical medicine, and Dr. G. A. Ransome to the medicine.

War Office

Brigadier Thomas Young, O.B.E., formerly direct medical services of the Far East Land Forces, has succ Brigadier A. E. Richmond, C.B.E., K.H.S., as director of health.

Dr. Ludwig Guttmann has left for Israel where he spend three weeks advising the medical authorities of government on the organisation of a centre for the treat and rehabilitation of paraplegics.

CORRIGENDUM: *Effect of the Head-down Position o Circulation in Hypotensive States.*—In the article of No (p. 941) the authors' appointments should read: A. Graham, lecturer in surgery for dental students; I Douglas, reader in experimental surgery.

Diary of the Week

gil of Wetzel (1941). Our classification has been ts following groups: obese (corresponding to 's channels A^4 and A^5), stocky (Wetzel's A^2 and mal (Wetzel's A^1, M^1, and B^1), slim (Wetzel's B^3), and undernourished (Wetzel's channel B^4). ing our subjects in this manner and allowing for ence of age and sex, we have compared the mean dices for the various types of physique (Cullum- al. 1949b). We conclude that physique does not play an important rôle in determining a person's to perform moderate exercise (Harvard step test), e slimmer or more linear the physique the greater endurance index. By contrast, we find that , speed, and the performance of moderate exercise e are all greatest in people of normal or stocky e.

hip with *Various Anthropometric Characters*

ising that the above-mentioned classification gure, though valuable in field work for rapid , is only crude, we have further analysed our data ence of relationship between various anthropo- measurements and indices and the fitness indices. s of correlation have been calculated, and the regression technique has been used in our (Cullumbine 1949e). By these means we have d the following significant correlations:

s index (pulse) positively with bi-iliac diameter, height, st circumference/height, with bi-iliac diameter, and gomatic diameter.

index (blood-pressure) positively with chest est breadth, and negatively with weight/height, est breadth, with chest length, with weight, and ght.

rance index (time) negatively with bi-iliac diameter d bi-iliac/bi-acromial diameter.

th, exhaustion time, and speed positively with area, with chest circumference/height, with chest rence, with chest breadth, with leg length, with bi-acromial, and bizygomatic diameter, and with

of these relationships may be only indirect , for example, some of the anthropometric ers are related significantly to physiological ers, such as vital capacity, resting pulse-rate, systolic blood-pressure, &c. (Cullumbine 1949f), latter are, as we have seen, also related to dynamic fitness. Thus, the fitness index (blood-pressure) is negatively correlated with height and weight in our subjects. Calculation of the partial correlation coefficients shows that the influence of height on the fitness index (blood-pressure) is due solely to its influence on the resting systolic blood-pressure.

However, our anthropometric-fitness correlations illustrate the type of person who has the better performances at different exercise tasks, and they agree, in general, with the findings of Woods et al. (1943) and others using somatotype ratings.

Environment and Economic Status

Perhaps the best demonstration of the reality of the above-mentioned correlation is seen when we consider the effect of environment and economic status on dynamic fitness. Ceylon can be divided into three main environments: the city of Colombo, the wet zone, and the dry zone. The distinction between the wet and the dry zones is based chiefly on their different average rainfalls during the S.W. monsoon. It is a real division from the points of view of the fertility of the soil and the prosperity, nutrition, and health of the people. The influence of age, sex, and race being allowed for, the mean fitness indices of the people living in these three environments have been compared (Cullumbine et al. 1949c). We find that people in the wet zone have a higher mean fitness index (pulse) than have those in the dry zone and in Colombo. The people of Colombo have a higher mean endurance time than have the people in the dry zone, and the latter have a greater mean endurance time than have the people in the wet zone. For strength, exhaustion time, and speed the descending order of the mean indices is wet zone, dry zone, and Colombo.

The people living in these three environments also show significant differences between their mean anthropometric characters (Cullumbine 1949g), and there is a very close correlation between these anthropometric differences and the differences between their fitness indices (Cullumbine 1949e). An example of this relationship is shown in table I, and the differences in body configuration seem to give a reasonable explanation of the differences in fitness of the peoples of the three main environments. These environmental differences are apparently not due to climatic differences at the time of the tests. All the tests were done during the "cool" calf in extension. For calculating the fitness indices, pulse-rate (in many cases heart-rate by auscultation over the chest) and brachial blood-pressure were estimated by two observers before and after each step test. In addition, details of each subject's age, sex, race, ancestry, diet, family occupations, and family income were recorded. The information about diet was later supplemented by a nutrition survey of many of the communities (Bibile et al. 1949).

RESULTS

Our findings have been reported *in extenso* elsewhere; so we confine ourselves here to discussing the information they give on the relation between dynamic fitness and age, sex, race, environment, body build, and muscular development. Most of the other relevant work has been done by Americans, and Cureton et al. (1947) have given an excellent summary of the published reports.

Age

The fitness index (pulse) for moderate exercise (Harvard step test) does not vary significantly during the pre-adolescent years, but there is a sudden decline at the age of 14. There is a further significant fall at the age of 17, and this is followed by a steady rise to a maximum between 21 and 25. Even this adult maximum, however, is less than the mean fitness index in the pre-adolescent years (Cullumbine et al. 1949b).

The fitness index (blood-pressure) falls steadily throughout life; hence the mean index for men in their fifties is less than half that for boys of 10, and the mean index for women over 40 is only about a third of that for girls of 10. Apparently a man's capacity for lowering his systolic blood-pressure after moderate exercise decreases more rapidly with age than does the capacity for slowing his post-exercise heart-rate.

The endurance indices for severe exercise (endurance step test) show an over-all variation with age very similar to that shown by the fitness index (pulse).

The exhaustion indices for protracted moderate exercise (exhaustion step test), speed, and strength all increase with age to maxima in early adult life.

Sex

The variation with age of the fitness indices is in general the same in either sex, but at all ages females give lower assessments than do males.

Muscular Development

The muscular development of the arm has been assessed (Cullumbine 1949b) by dividing the sum of the greatest circumferences of the right arm and forearm by the subject's height, and that of the leg by dividing the sum of the greatest circumferences of the right thigh and calf by the height. This method ignores the thickness of the skin and subcutaneous fat, but Ceylonese are so devoid of fat that this is probably justified.

We have found a significant but negative correlation between leg-muscle development and the fitness index (pulse) ($r = -0{\cdot}8682$ for 500 subjects chosen at random), and between leg-muscle development and endurance time ($r = -0{\cdot}3838$ for 500 subjects chosen at random). This means that the less is a person's muscular development the greater are his fitness index (pulse) and his endurance time. Perhaps the less the muscular development the less is the strain on the circulation in supplying an increased blood-flow through the muscles during activity.

Leg-muscle development and exhaustion time are not correlated significantly ($r = -0{\cdot}2911$ for 1000 subjects), but leg-muscle development and speed are correlated ($r = +0{\cdot}3873$ for 500 subjects). Similarly, strength and arm-muscle development are positively and very significantly correlated ($r = +0{\cdot}9124$ for 500 subjects).

Resting Cardiovascular State

The coefficients of correlation (r) between the sitting pulse-rate, the sitting systolic and diastolic blood-pressure and pulse-pressure, and the various
indices have been calculated from the data for
subjects (Cullumbine 1949c). We find that the si
pulse-rate is not correlated significantly with s
endurance time, or strength, but it is correlated s
cantly with the fitness index (pulse) ($r = -0{\cdot}3740$
possibly with exhaustion time ($r = -0{\cdot}2002$).
means that people with relatively slow resting pulse
have relatively slow pulse-rates after moderate exe

The sitting systolic blood-pressure is not corr
significantly with endurance time, but is correlated
the fitness index (pulse) ($r = -0{\cdot}2378$), with
($r = +0{\cdot}3215$), with exhaustion time ($r = +0{\cdot}2003$
with strength ($r = +0{\cdot}5710$).

The sitting diastolic blood-pressure is corr
significantly with the fitness index (pulse) ($r = -0$
but not with the other indices, and the sitting
pressure is not correlated significantly with any
indices.

Therefore our results suggest that the slower the r
pulse-rate the slower is the pulse-rate after mo
exercise. This agrees with the findings of most ob
Similarly, the lower the resting systolic blood-pr
the lower is the post-exercise systolic blood-pressur
5 minutes' moderate effort. Conversely, the high
resting systolic blood-pressure the greater are the
of movement, the strength, and the time of perfor
of moderate exercise to fatigue.

Respiratory Efficiency

Many tests have been suggested for assessing r
tory efficiency. These include the breath-holding
a measurement of the respiratory force, Flack's
test, and a simple measurement of the vital cap
We have used all these tests and conclude that ou
vital capacity is correlated significantly with a pe
capacity for exercise, and then only with endu
time (Cullumbine and Williams 1949). Presumabl
is because severe, and not moderate, exercise invol
oxygen debt, and the magnitude of the oxygen
which can be achieved or sustained may be rela
the capacity of the respiratory tract—i.e., to the
capacity.

Blood Hæmoglobin

Since hæmoglobin is the oxygen carrier betwee
lungs and the active tissues, we might expect to
relationship between exercise ability and hæmo
level. In fact, we have found that this level is corr
significantly with speed, strength, and exhaustion
(Cullumbine 1949d). It is understandable ho
oxygen-carrying capacity of the blood may lim
least partly, the response to protracted muscular
but it is difficult to see how it can help to dete
speed and strength. Some common causal factor
nutritional status—may be involved.

The hæmoglobin level is not correlated with the
index (pulse). This agrees with the conclusio
Spealman et al. (1948) and is to be expected, since
is a large reserve of oxygen-carrying power in a
the most anæmic persons, and moderate exercise of
duration would not unduly strain this reserve.
the hæmoglobin concentration related significant
endurance time. Perhaps, in this case, the exer
so severe that the oxygen debt acquired is too la
be influenced by the rather small range of hæmo
levels presented by our normal subjects.

Physique

Sheldon's classification into somatotypes (Shel
al. 1940) is probably the most accurate method av
for grading people according to body type. For acc
this requires three photographs of each person ta
standard positions, which was impossible in our
survey. As an alternative, though admittedly
accurate, method of grading we have used the

grid of Wetzel (1941). Our classification has been he following groups: obese (corresponding to 's channels A^4 and A^5), stocky (Wetzel's A^2 and rmal (Wetzel's A^1, M^1, and B^1), slim (Wetzel's B^3), and undernourished (Wetzel's channel B^4). ifying our subjects in this manner and allowing for uence of age and sex, we have compared the mean indices for the various types of physique (Cullum- al. 1949b). We conclude that physique does not o play an important rôle in determining a person's to perform moderate exercise (Harvard step test), e slimmer or more linear the physique the greater endurance index. By contrast, we find that h, speed, and the performance of moderate exercise gue are all greatest in people of normal or stocky ne.

nship with Various Anthropometric Characters

gnising that the above-mentioned classification sique, though valuable in field work for rapid g, is only crude, we have further analysed our data idence of relationship between various anthropo- measurements and indices and the fitness indices. ients of correlation have been calculated, and the le-regression technique has been used in our s (Cullumbine 1949e). By these means we have ied the following significant correlations:

ss index (pulse) positively with bi-iliac diameter/height, hest circumference/height, with bi-iliac diameter, and ygomatic diameter.

index (blood-pressure) positively with chest chest breadth, and negatively with weight/height, hest breadth, with chest length, with weight, and eight.

lurance index (time) negatively with bi-iliac diameter ith bi-iliac/bi-acromial diameter.

ngth, exhaustion time, and speed positively with e area, with chest circumference/height, with chest nference, with chest breadth, with leg length, with , bi-acromial, and bizygomatic diameter, and with .

me of these relationships may be only indirect use, for example, some of the anthropometric cters are related significantly to physiological cters, such as vital capacity, resting pulse-rate, ng systolic blood-pressure, &c. (Cullumbine 1949f), the latter are, as we have seen, also related to dynamic fitness. Thus, the fitness index (blood-pressure) is negatively correlated with height and weight in our subjects. Calculation of the partial correlation coefficients shows that the influence of height on the fitness index (blood-pressure) is due solely to its influence on the resting systolic blood-pressure.

However, our anthropometric-fitness correlations illustrate the type of person who has the better performances at different exercise tasks, and they agree, in general, with the findings of Woods et al. (1943) and others using somatotype ratings.

Environment and Economic Status

Perhaps the best demonstration of the reality of the above-mentioned correlation is seen when we consider the effect of environment and economic status on dynamic fitness. Ceylon can be divided into three main environments: the city of Colombo, the wet zone, and the dry zone. The distinction between the wet and the dry zones is based chiefly on their different average rainfalls during the S.W. monsoon. It is a real division from the points of view of the fertility of the soil and the prosperity, nutrition, and health of the people. The influence of age, sex, and race being allowed for, the mean fitness indices of the people living in these three environments have been compared (Cullumbine et al. 1949c). We find that people in the wet zone have a higher mean fitness index (pulse) than have those in the dry zone and in Colombo. The people of Colombo have a higher mean endurance time than have the people in the dry zone, and the latter have a greater mean endurance time than have the people in the wet zone. For strength, exhaustion time, and speed the descending order of the mean indices is wet zone, dry zone, and Colombo.

The people living in these three environments also show significant differences between their mean anthropometric characters (Cullumbine 1949g), and there is a very close correlation between these anthropometric differences and the differences between their fitness indices (Cullumbine 1949e). An example of this relationship is shown in table I, and the differences in body configuration seem to give a reasonable explanation of the differences in fitness of the peoples of the three main environments. These environmental differences are apparently not due to climatic differences at the time of the tests. All the tests were done during the "cool"

TABLE II—RELATION BETWEEN DYNAMIC FITNESS AND PHYSIOLOGICAL AND ANTHROPOMETRIC CHARA

Rapid severe effort	None	None	+	None	–	Slim best	Decreases with age	Negative with hip width; and hip width to shoulders
Moderate effort for 5 minutes	–	–	None	None	–	No correlation	Decreases with age	Positive with hip width; negative with height, weight/height, chest breadth and

season, and we could find no relationship between fitness and air temperature, relative humidity, and effective temperature.

We have also classified our subjects according to their economic status. From information on family income, family occupations, size of family, &c., we have distinguished three income groups—low, intermediate, and higher. These groups differ in their mean dynamic fitness, the intermediate income group having a significantly greater mean fitness index (pulse) and a greater endurance time than the low or higher groups, whereas the higher-income group has greater means of strength, exhaustion time, and speed than the intermediate group, which in turn has greater means than the low-income group. As would be expected, we have found differences in the anthropometric characters between the three income groups (Cullumbine 1949g), and these anthropometric differences again parallel the fitness differences (see table I).

Race

Since exercise-performance ability is correlated with certain anthropometric characters, and since anthropometric differences are known to exist between persons of different races, are there distinguishable racial differences in exercise ability? Our data indicate that there are. No significant racial differences in fitness index (pulse) have emerged, but both the Sinhalese and the Indian Tamil have a greater mean endurance time than the Ceylon Tamil. In strength, exhaustion time, and speed the means for the Sinhalese are greater than those for the Ceylon Tamil and the Ceylon Moor. These racial differences in fitness indices are paralleled by the differences in anthropometric characters (table I), but the correspondence is not so close as in the case of the environmental and economic differences. Thus, the bi-iliac/height and the chest-circumference/height indices differ between races and are correlated with the fitness index (pulse), which, however, does not vary significantly between races.

This emphasises the fact that there are influences other than anthropometric ones which can affect dynamic fitness. We have shown, for example, that the fitness index (pulse) is correlated negatively with the resting pulse-rate and with leg-muscle development, which, like the fitness index (pulse), do not vary with race (Cullumbine 1949b and f).

DISCUSSION

We have postulated that there are at least five basic aspects of dynamic fitness: speed, strength, the ability to perform moderate exercise of relatively short duration (as measured by the fitness indices), the ability to perform rapid severe exercise (as measured by the endurance
indices), and the ability to perform moderate
for a long time (as measured by the exhaustion in
and we have shown how each of these aspects
influenced by age, sex, resting cardiovascular
respiratory efficiency, hæmoglobin concentration,
configuration, muscular development, racial c
teristics, and gross environment. From our resul
clear that these five basic aspects can be placed in
groups: (1) strength, fitness for protracted mo
exercise, and speed; and (2) fitness for modera
severe exercise (table II).

The first group are very similarly related with
measurements, resting systolic blood-pressure, mu
development, and hæmoglobin level. They are, in g
correlated with the physical and physiological cha
which increase with age, and they themselves also i
with age (significant correlations are still obtainabl
the influence of age is eliminated). These three
are also correlated with each other. Thus, spe
endurance time are very significantly correlated
0 9922 (Cullumbine et al. 1949a). This group a
influenced in much the same way by environ
factors, race, and sex. The related body measur
are influenced in a corresponding manner by e
ment, race, and sex, but factors other than these
physical characters may also be important. The
globin content of the blood, for example, is gre
Ceylonese males than in Ceylonese females, gre
the wet zone than in the dry, greater in the higher-
group, and greater in Sinhalese then in Ceylon
Ceylon Moor, and Indian Tamil (Bibile et al.
Strength, exhaustion time, and speed have a
variation.

The indices for moderate and for severe exer
contrast, tend to decrease with age and are neg
correlated with leg-muscle development. Leg
development is not influenced by age (Cullumbine
nor can variations in leg-muscle development
environment explain the differences noted for
two aspects of fitness between people in di
environments.

The resting systolic blood-pressure of Ce
increases with age to reach a maximum in earl
life (Cullumbine 1949h); and, since this pre
negatively correlated with the fitness indices, t
with age would favour a fall in the indices. On th
hand, the fitness index (pulse) is negatively cor
with the resting pulse-rate, which tends to decre
age in Ceylonese (Cullumbine 1949h); this d
would favour a rise in the fitness index (pulse).
capacity and endurance time are positively cor
but vital capacity increases with age in Ce
(Cullumbine 1949i), and racial variations in vital c

t correspond to the racial variations in endurance Similarly, the anthropometric characters increase, nain constant, with age. It is clear that, though physical and physiological factors are known to ncerned in exercise performance, our knowledge far from complete.

influence of environment on physical or static and on dynamic fitness may be purely dietary. Bibile et al. (1949) have shown that the diets of in the dry zone and in the low-income group are r in every respect to those of people in the wet nd in the intermediate and higher income groups. e other hand, such debilitating diseases as hook- infestation and malaria are more common in the ne and among the poorer classes.

literature on the influence of diet on fitness for lar activity is voluminous but conflicting. Though dmitted that protracted semi-starvation causes a nd decrease in muscular performance (Henschel the optimum vitamin requirements for fitness for lar effort are still not settled. Comroe and Dripps and Cullumbine et al. (1949c), who have reviewed ork done on this subject, conclude that further ted and adequately controlled experiments are ry before the effects of vitamin deficiencies on ic fitness can be accurately assessed.

assessment of possible dietary influences on ic fitness during field work is complicated by the at this functional fitness can be improved by regular exercise, whether occupational or recrea- (Cullumbine 1949j). Therefore there is here a y compensating factor in that the poor often have harder to obtain a living, and hard work increases unctional fitness. Their inferior nutritional status mit the improvement produced in this way, but portant to recognise this secondary factor.

her progress in this type of "field physiology" bably depend on the elaboration of more sensitive s for assessing dynamic fitness. The first attempts ss fitness concentrated on body build, muscular ment, and strength (Sargent 1903, Martin 1921). the emphasis moved to a measurement of the cardiovascular state (Meylan 1913, Crampton 1915, er 1920, and others). At about the same time, nse to the needs of the Services for fitness tests g personnel, "respiratory efficiency" tests were d (Flack 1921, Schneider 1921). Most of these ere of limited value because they ignored the c aspects of fitness, and it was only later that al tests, involving measurement of the physio- response of people to standard exercise, were ced.

treadmill is probably the best apparatus for l laboratory investigations, since the technique ly acquired and the true work efficiency remains t (Taylor and Brozek 1944). It is, however, ly costly and is unsuitable for field work. The l step test, which requires only a stool and little at present the most useful test for field work. essment is based on the post-exercise pulse-rate. course, is not a new basis for a fitness test— nd Pembrey (1911), Foster (1914), Cotton et al. Hunt and Pembrey (1921), and Poulton and 1926), among others, used a similar criterion— Campbell (1925) indicated, most of these workers sidered the resting pulse-rate in their calculations, ended to give people with a high initial pulse-rate ntage. What we now require are reliable tests e of the other physiological characters, such as one and nervous and neuromuscular coördination.

SUMMARY

of the data obtained during a nation-wide survey eoples of Ceylon are summarised.

The influence of age, sex, race, muscular development, physique, anthropometric characters, resting cardiovascular state, respiratory efficiency, and gross environment on certain aspects of dynamic fitness is discussed.

Withering (1785) was the first to show that digitalis often relieved dropsy and slowed the heart. Mackenzie (1910) found that cardiac œdema was greatest in cases of heart-failure due to valvular disease with auricular fibrillation; when digitalis removed the œdema the ventricular rate became much slower. His cases of heart-failure with sinus rhythm had less œdema and the improvement following digitalis was less apparent; only rarely was there conspicuous slowing of the heart-rate. This led Mackenzie to teach that digitalis exerted its most beneficial effect in cases of auricular fibrillation, and that cardiac slowing was an index of therapeutic benefit.

Lewis (1919) was even more strongly of the opinion that auricular fibrillation was the only indication for digitalis. He wrote: "There are few, if any, instances of which we know with certainty in which digitalis acts beneficially except cases of accelerated action; there are

few instances of acceleration in which the drug produces unquestionable benefit apart from those provoked by fibrillation of the auricles." This view was shared by many but not all of his contemporaries. For some years previously Wenckebach (1910) had maintained that the drug was of value in all types of heart-failure and that its use should not be restricted to cases with a quick and irregular pulse. He said: "If ever I should acquire a reputation for treating heart patients with success, it will be from my giving in this way digitalis where authorities and textbooks forbid it." Windle (1916) wrote of the value of digitalis in patients with dropsy and pulsus alternans due to myocardial and arterial disease. West and Pratt (1920) found that "in many [patients with heart-failure in sinus rhythm] the effects were quite as *gratifying as in those showing auricular fibrillation.*" Christian (1919, 1922) reported a series of 97 cases treated with digitalis. He found as satisfactory a response in cases with sinus rhythm, in which the pulse-rate remained unaltered, as in those with auricular fibrillation. Further clinical studies by Luten (1924) and by Marvin (1926) indicated that the response of the failing heart to digitalis was related more to the ætiology of the cardiac condition than to the rhythm or rate. They reported strikingly beneficial results in patients with hypertensive or ischæmic heart-disease, but a failure of response in those with rheumatic valvular disease in sinus rhythm who had progressed to the stage of persistent œdema. Luten stated that "slowing is not a characteristic attendant on improvement and even when it occurs it is a result rather than a cause of the improvement." Gavey and Parkinson (1939) also concluded that digitalis was indicated in congestive cardiac failure irrespective of the rhythm. They claimed a parti value for the drug in rheumatic valvular disease ac panied by auricular fibrillation; but statistical an of their results does not show a significant diffe between the responses of patients with sinus rh and those with auricular fibrillation.

The development of the technique of cardiac c torisation has brought further information on pharmacological action of t [illegible] studies by McMichael and [illegible] by Ahmed et al. (1949) have shown that digoxin ouabain increase the cardiac output in patients failure due to hypertensive, ischæmic, and val heart-disease. In the course of the earlier observat McMichael and Sharpey-Schafer noted that 6 pat *with auricular fibrillation* showed a response to dig similar in degree to that observed in those with rhythm, but apart from this there is little referenc the relation between increase in cardiac output decrease in heart-rate. The following observations made in order to determine whether cardiac slo plays an important part in increasing the cardiac ou following digitalis therapy.

MATERIAL AND METHODS

Cardiac catheterisation was carried out two h after the midday meal by a technique similar to described by McMichael and Sharpey-Schafer (194 Patients not in cardiac failure lay flat; *those in fai* were propped up. The right auricular pressure recorded on a saline manometer and related to the l of the sternal angle which was taken as zero. oxygen unsaturation of 3 ml. samples of mixed ve

results are shown in tables I–IV and figs. 1

se to Digoxin

ents with Sinus Rhythm.—Of the 12 patients in oup (table I), 5 had hypertensive heart-disease and ular disease. In all but 2 of the 12 digoxin caused of the heart-rate, by 2–14 beats per minute. with hypertensive failure showed a rise in cardiac with a marked fall in right auricular pressure. 7 with valvular disease only 3 showed a significant output (10% or more); 6 showed a fall in filling re.

ents with Auricular Fibrillation.—Of the 15 patients group (table II) 4 had hypertensive heart-disease 1 valvular disease. In 3 of the hypertensive ts the cardiac output rose and the right auricular re fell, but in the fourth (case 14) there was no rise put and the right auricular pressure was unchanged. eart-rate slowed in all 4 cases. Of the patients valvular disease only half showed a significant se in output, despite a fall in right auricular re in all but 1 (case 25). The heart-rate slowed by beats per minute in these patients whether the c output increased or not.

increase in cardiac output may not necessarily pany clinical improvement. Quite often a fall in s pressure occurs which is not associated with a cant rise in cardiac output (McMichael and Sharpey-er 1944a, and unpublished observations). The degree of cardiac slowing has therefore been plotted against the measured reduction of venous pressure (fig. 1). Neither in the patients with sinus rhythm nor in those with auricular fibrillation is there any correlation between the relief of congestion and the slowing in heart-rate.

Response to Atropine

Atropine alone was given to 20 patients, of whom 14 had apparently normal circulations, 3 had heart-block, 1 had mitral stenosis and auricular fibrillation without evidence of venous congestion, and 2 had congestive failure due to hypertension with sinus rhythm (table III). After the injection of atropine all responded with an acceleration in heart-rate, which appeared within one minute and reached its maximum in two minutes. The increase in rate was variable. No change in blood-pressure was noted. The usual response in normal subjects was a fall in right auricular pressure and an increase in cardiac output. These changes were fairly consistent, and one or two apparent exceptions in the table may well be accounted for by the random errors involved. In the small group of patients with heart-disease similar changes were observed—i.e., the cardiac output tended to increase and the venous pressure fell. While it would be unwise to claim that patients with cardiac failure would all be expected to respond in this manner, it is significant that atropine-induced acceleration did not lower cardiac output or increase congestion.

Atropine following Digoxin.—Previous studies by Ahmed at al. (1949) have shown that intravenous digoxin usually alters the cardiac output within 30–45 minutes. One hour was, therefore, allowed to elapse before giving atropine (table IV). The acceleration in rate was variable; the cardiac output either remained unchanged or showed a further slight rise above the level achieved by digoxin. The right auricular pressure usually underwent a slight fall or remained unchanged. In only 1 case did it rise by 2 cm. (case 18). There is no correlation between the degree of rate change and the magnitude of the cardiac output or venous pressure alteration.

DISCUSSION

Figs. 1 and 2 indicate that in chronic heart-failure digoxin produces a response which, measured by cardiac output and by venous-pressure changes, bears no relation to the degree of slowing achieved. Further, the rise in cardiac output is as pronounced in cases with sinus rhythm as in those with auricular fibrillation. In some cases of auricular fibrillation the ventricular rate slows considerably but cardiac output does not rise; others with sinus rhythm may respond excellently with little or no change in rate. Slowing is more conspicuous in auricular fibrillation but does not appear to play any part in improving the cardiac output. The output seems to increase equally well whether the initial ventricular rate is fast or slow; this holds irrespective of the rhythm.

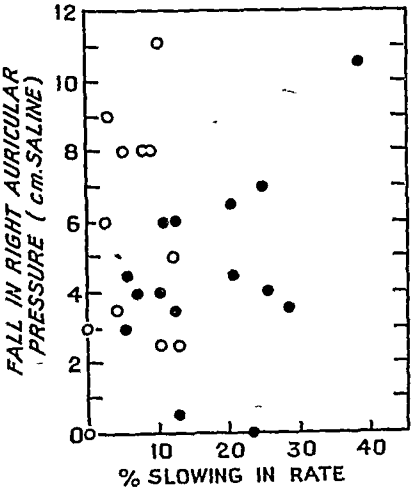

Fig. 1—Responses to digoxin. Open circles, sinus rhythm; dots, auricular fibrillation. There is a greater degree of slowing in fibrillation than in sinus rhythm, but there is no significant difference in the relief of venous congestion in the two groups.

These observations supplement the modern views on the clinical use of digitalis which date from Wenckebach (1910) and Christian (1919, 1922), and are contrary to the older teaching of Mackenzie (1910), Lewis (1919), and Sutherland (1919). The fact that atropine can reverse the slowing effect of digoxin, without lowering the cardiac output to the level which existed before digoxin was given, is further evidence of the unimportance of rate change in digitalis therapy. It may be, as Luten (1924) suggested, that a tachycardia in failure is purely an adaptative mechanism of an embarrassed circulation, and that as the circulation improves the heart slows secondarily.

It is to be noted that the above observations covered only an hour or two, and it is possible that clinical responses over a longer period might be different. But the clinical studies of Christian (1919, 1922) and Gavey and Parkinson (1939) do not suggest that the long-term clinical results in sinus rhythm and auricular fibrillation differ significantly. It would be difficult to assert that in mitral stenosis the onset of auricular fibrillation no part in making the situation worse. On the hand, auricular fibrillation may have no delete effects in otherwise healthy hearts (Hanson and Rut 1949).

The opinion that digitalis is of particular val auricular fibrillation may be due partly to the fact slowing of the heart-rate provides a convenient ind effective dosage. This dosage indicator is lacki patients with sinus rhythm, who while undergoing continued digitalis therapy are more liable to almost imperceptibly between a state of digitalis dosage and underdosage. This readily create impression that the drug is of less value in sinus rh than in auricular fibrillation.

SUMMARY

When digoxin is given in cardiac failure the r cardiac output is as pronounced in patients with rhythm as in those with auricular fibrillation.

There is no relation between the degree of slowin the increase in cardiac output; relief of venous cong is also independent of the degree of slowing. Im ment in ca output is e probable w the initial cular rate i or fast.

In normal atropine ac tion is accom by a fall in auricular p and a rise in c output. P with heart- showed esse similar resp There was n dence that ac tion so in either dep cardiac out increased congestion.

Given aft oxin in fibr hearts, atrop reverse the effect wi countera either the

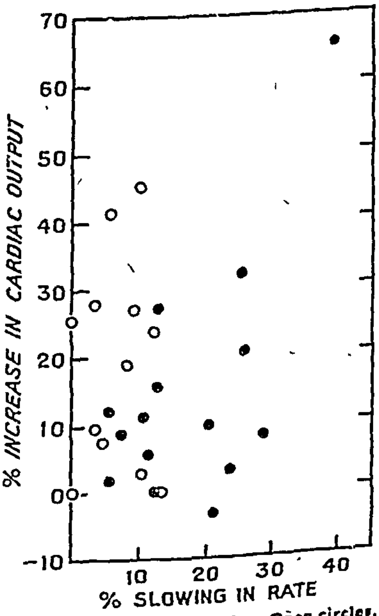

Fig. 2—Responses to digoxin. Open circles, sinus rhythm; dots, auricular fibrillation. There is a greater degree of slowing in fibrillation than in sinus rhythm, but there is no significant difference in the cardiac output responses of the two groups.

c output or the fall in venous pressure caused goxin. Similarly in patients with sinus rhythm ne acceleration has no adverse effect on cardiac t or venous pressure after digitalisation.

presence or absence of cardiac slowing plays no rable part in producing the immediate hæmo- aic improvements following digitalisation.

e of the data given above were obtained by Prof. A. D. ield, Dr. Sheila Howarth, Prof. J. McMichael, and E. P. Sharpey-Schafer, to whom we are indebted. We like to thank Professor McMichael for his help and agement.

URCE OF TWO HOSPITAL-INFECTED CASES OF TETANUS

S. SEVITT
M.A., M.D., M.Sc. Dubl., M.R.C.P.I., D.P.H.

o patients who had received surgical treatment in ame hospital developed tetanus in May, 1949.

se 1.—A married woman, aged 60, first attended hospital ug. 3, 1948, with a fracture dislocation of the ankle. was treated in plaster and later became displaced. rly October open reduction was done and treatment in r was continued until Jan. 20, 1949. The operation ds healed uneventfully.

May 2, 1949, the patient was readmitted with intolerably al arthritis, and arthrodesis of the ankle was done in ain theatre suite (theatre 1) on May 4. Postoperatively patient developed a thrombosis of the main vessels e calf, and on May 6 an operation was done to explore decompress the leg. Circulation returned, and after a ing had been done on May 17 the patient's general tion greatly improved. No other dressings were rmed.

May 19 trismus developed, and spasm of the neck and geal muscles rapidly followed. Tetanus was diagnosed, n spite of anti-tetanus serum and hypnotics the patient on May 23.

cteriological examination of the wound at the time of leath did not reveal tetanus or other clostridia. It was ght probable that the infection had been introduced e operation on May 4, after which the conditions were that growth of these organisms in the wound would bly have been encouraged. The latent period was about fifteen days.

se 2.—A man, aged 52, sustained in January, 1948, a re fracture of the left tibia and fibula. Open reduction done. Subsequently, after an injury in plaster, the nd became septic. On April 26, 1949, the leg was utated below the knee through a relatively healthy area; was done in theatre 1. The wound was left open, secondary re being done on May 1 with one draining tube. The nd healed uneventfully and the patient was discharged May 20. The wound was dressed several times in this .

n May 25 the patient attended the outpatient department plaining of difficulty in opening his mouth and of pain stiffness of the neck. Tetanus developed, from which ecovered.

acteriological examination of a tiny area of the amputation np which remained unhealed did not reveal tetanus bacilli or other clostridia. The most likely time for infection to occur would have been when the wound was closed on May 1, 1949—i.e., within three days of the operation on case 1. This would give a latent period of twenty-four days.

In neither case was catgut used, the surgeon having used sterilised silk for all sutures.

THE OPERATING-THEATRE AS A POSSIBLE SOURCE OF INFECTION

The main theatre suite is situated on the top floor of a four-storied building and consists of two theatres communicating through a central assembly room. Attached to each theatre are the usual anæsthetising-room and sterilising-room (see figure). The ceiling of theatre 1 collapsed on Nov. 20, 1948, and towards the end of February, 1949, building repairs were begun. These were completed on April 16, when this theatre (henceforth referred to as the theatre-in-use) was reopened for surgery. On April 18 building reconstruction was begun on the adjoining theatre 2 (henceforth referred to as the theatre-under-repair), the assembly room, and the annexes, and was in progress when the cases of tetanus arose.

During this time large amounts of building materials were being used in the theatre-under-repair; these included cement and plaster, the latter containing animal hair. In addition, this material, which will be referred to as plaster-hair, was present in bulk in several sacks. The plasterers beat the hair with laths on a table before mixing it with the plaster, in which it acts as a binding material. The rooms in which building and plastering were in progress contained a thick layer of dust in which this plaster-hair was present. It seemed possible that the abnormal quantity of dust contaminated with animal hair was a potential source of tetanus spores.

Theatre Ventilation

The ventilation of the theatre suite (see figure) was produced by two independent fan-driven exhaust units. The two air outlets (O_1 and O_2 in the figure) were situated on the outside walls of the theatre; each communicated with an independent system of air ducts and vents (V_1 and V_2 in the figure) and drew air from each theatre and its sterilising-room and anæsthetising-room into the open air outside. This produced various currents of air throughout the theatre suite, some of which amounted to draughts. The air drawn into the theatre suite came up the lift shafts and stairway.

During the repairs only the air ventilation of the theatre-in-use was in operation. A trial run of this unit showed that strong currents of air were created, including cross-currents from the theatre-under-repair which contained large quantities of dust. Dust from this location must therefore have been drawn into the theatre-in-use and its various annexes while the ventilation unit was working.

BACTERIOLOGICAL INVESTIGATION

The bacteriological investigation was therefore conducted to answer the following questions:

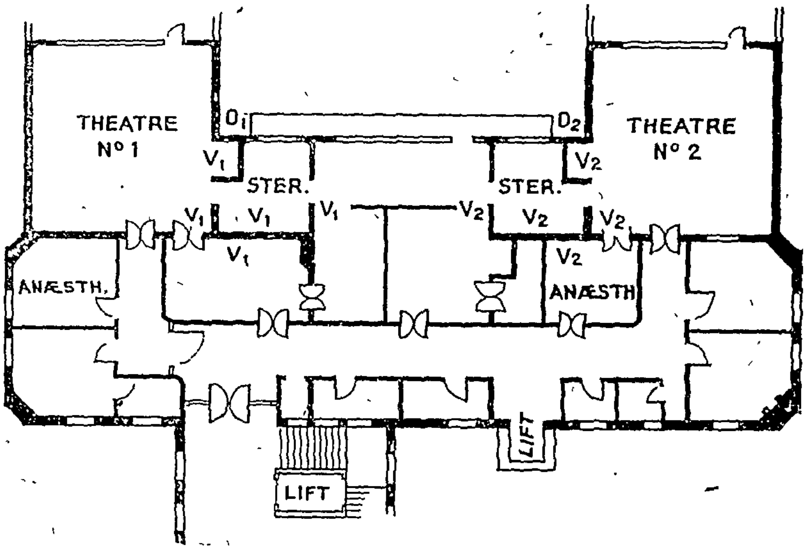
(1) Did there exist within the theatre suite a potent source of tetanus spores? The plaster-hair was a likely example of such a material.

(2) If tetanus spores were present within the theatre, where were they mainly concentrated, and how widely were they disseminated?

(3) Were the operating-materials, such as silk sutures, talcum powder, gloves, and dressings, contaminated with tetanus spores?

The following specimens or swabs were therefore collected and examined bacteriologically:

(1) Fourteen swabs from various areas of the floor and walls of the theatre-in-use and its anæsthetics-room, the theatre table and table rubber, and the anæsthetics trolley.



Plan of main theatre suite: O_1, O_2, outlets of fan-driven exhaust ventilators; V_1, V_2, air vents in theatre and annexes.

(2) Specimens of dust swept from the main corridor of the theatre, and dust from two parts of the theatre-under-repair and its sterilising-room.

(3) Samples of air from the theatre-in-use, the theatre-under-repair, and the central assembly room. These were collected by an apparatus constructed to bubble air through 200 ml. of Brewer's thioglycolic-acid broth contained in a 500 ml. triangular flask. Each sampling lasted half an hour, and it is estimated that about 30 c. ft. of air was bubbled through in each sample. During the sampling no operations were being done, but building was in progress. The flasks of broth were heated to 90°C for ten minutes and incubated for seven days.

(4) Four samples of the plaster-hair removed from sacks of this material.

(5) Samples of sterilised silk sutures, swabs of the exterior of sterilised rubber gloves, samples of sterilised cotton-wool, two samples of talcum powder before autoclaving, and two samples of talcum powder already autoclaved and ready for use.

Methods

The various swabs and samples of dust, hair, silk sutures, cotton-wool, and talcum powder were plated directly on to 2% horse-blood agar plates, both aerobically and anaerobically, and inoculated into Robertson's cooked-meat broth. The cooked-meat cultures were examined after 2, 7, and 14 days' incubation. Duplicate subculture was made on to blood-agar plates, which were incubated aerobically and anaerobically, sometimes after heating a portion of the culture to 80° or 90°C for 5–15 minutes. Aerobic bacteria, such as micrococci, diphtheroids, and streptococci, and aerobic sporing bacilli (*Bact. subtilis* group) were identified by the usual methods. Special attempts were made to isolate anthrax bacilli from the plaster-hair by cultural methods and to produce anthrax by inoculation of hair washings into guineapigs.

Difficulty was encountered in ob pure cultures of the anaerobic s bacilli. The technique of subcul the cooked-meat cultures on to 2% blood agar, which was done in the stages of the investigation, was soon up, because with this concentrat agar many clostridial colonies sprea the surface of the plates. Bloo containing 6% of agar was the used,[1] and pure cultures were o by subculture from the cooke cultures on to these 6% bloo plates. The plates were incubated a bically, and subsequent colonies picked into cooked-meat media. process was repeated several tim each strain.

Identification of *Clostridium teta* based on its characteristic dru appearance when sporing; limite teolytic properties in cooked-meat, and serum media; colonial charact (spreading growth, &c.); product indole in peptone water; and inability to fermen sugar media, &c. Finally, toxigenicity was determi (1) the production of fatal clinical tetanus in mice lated with broth cultures to which calcium chlori been added, and (2) the protective action of liminary injection of tetanus antitoxin in ot similarly injected animals.

Other members of the clostridia group were is and 24 strains were examined. The investiga these organisms included the morphology, in pa the shape and position of the spores and motility teolytic action in cooked-meat broth, nutrient coagulated serum, and coagulated egg media; sac lytic properties in iron-sugar peptone-water medi taining glucose, maltose, mannite, lactose, sacc or salicin); production of indole in peptone Nägler reaction; action on litmus milk, &c. attempts were made to produce gas-gangrene in pigs by the intramuscular inoculation of broth c of ten of the strains isolated. To these cultures a s of calcium chloride was added.

RESULTS

The results of the anaerobic cultures are sumn in the accompanying table.

Air Sample.—No anaerobic bacteria were isolate the air of the theatre suite.

Theatre-under-repair and its Sterilising-room.—Th from both of these rooms contained *Cl. teta* various other strains of clostridial organisms, inc *Cl. sporogenes.*

ster-hair.—This material contained very large pers of various kinds of bacteria, including varieties erobic sporing bacilli and micrococci. Anthrax li were not isolated, nor was anthrax produced in apigs by inoculation of hair washings. In the ed-meat cultures a heavy mixed growth of anaerobic ng bacilli was obtained within forty-eight hours. these cultures strains of toxigenic *Cl. tetani* were ted. Among the various other anaerobes present *bifermentans*, *Cl. sporogenes*, and *Cl. histolyticum* identified, but others were also present. Several of naerobes from the hair and from the other sources uced necrosis, liquefaction, and œdema of muscle out killing the guineapigs. Moreover, when the rifuged deposit of washings from the hair was inocu-l into the thigh muscles of two guineapigs, a large of muscle necrosis developed, and in one guineapig efaction of the muscle and pus formation took place. ure of the muscle and pus produced heavy growths naerobic sporing bacilli.

ain Corridor of Theatre.—The dust examined yielded ms of *Cl. tetani*, *Cl. bifermentans*, *Cl. sporogenes*, and her clostridial strain.

heatre-in-use.—From the operating-room large num- of aerobic sporing bacilli and various micrococci obtained from every swab of the floor and walls. ddition, one swab yielded coliform bacilli, and from ther an oval subterminal anaerobic sporing bacillus grown.

heatre Table and Table Rubber.—Heavy growths of bic sporing bacilli and various micrococci were ined. From the table rubber a diphtheroid bacillus a non-hæmolytic streptococcus were also isolated, these were probably of human origin. No anaerobic teria were found.

terilised Silk Sutures and Cotton-wool, Swabs of oclaved Rubber Gloves.—Cultures were sterile.

alcum Powder (Glove Powder).—Four specimens of um powder were cultured, two before sterilisation two already autoclaved and ready for use. From unsterilised specimens several varieties of anaerobic ring bacilli were cultured, including *Cl. sporogenes*, from one specimen *Cl. tetani* was isolated. The oclaved specimens yielded three varieties of clostridia, which *Cl. tetani* and *Cl. sporogenes* were identified. n-sporing bacteria were not isolated.

t was obviously important to discover whether the um powder had been contaminated in the theatre te or had arrived already contaminated from the pensary. Accordingly specimens of the stock dispensary um powder were cultured. A few aerobic sporing illi and staphylococci were found, but anaerobic ring bacilli were not isolated. Further specimens talcum powder before and after autoclaving were ained from the operating-theatre in the casualty partment. This theatre is located on the ground floor the hospital and is some distance from the main theatre te, and its autoclaving is done in a separate depart-ent. Both of these specimens of talcum powder mained sterile. The failure to culture anaerobic oring bacilli from these specimens of talcum powder ggested that the main theatre talc had been con-minated within the theatre. If this were so, it was nportant to find out why the autoclaved cotton-wool and ubber gloves were sterile, the latter autoclaved only t 5 lb. steam pressure for ten minutes, whereas talcum owder after autoclaving at 20 lb. pressure for twenty minutes still contained spores.

Questioning of the theatre staff revealed that the nethod of packing the talcum powder had been changed, probably in April, 1949. Previously the powder had been packed in "pepper-pots" before sterilisation; but, owing to a shortage of these, the talc was now packed in flat packets of gauze, each containing a teaspoonful of powder. These were not wrapped in paper, and numerous talc-containing pieces of gauze were packed side by side and on top of one another in a metal drum. Inspection showed that it was a drum three-quarters full of talcum powder containing many pieces of gauze. It seemed that sterilisation by autoclaving would be relatively ineffective, since the air would be slow to leave and steam slow to enter, and consequently the temperature of the talcum powder would not rise sufficiently to destroy the spores of bacteria. A test was carried out to see if this were so. A small sterilising drum was three-quarters filled with pieces of gauze each containing a teaspoonful of talc, and a piece of gauze contaminated with cultures of *Bact. subtilis*, *Bact. coli*, and *Staph. aureus* was marked and placed in the centre of the drum. This was autoclaved in the laboratory at 20 lb. pressure for 20 minutes. Culture of the marked piece of gauze showed that the staphylococcus and *Bact. coli* had been killed, but that the *Bact. subtilis* had survived the autoclaving. In other words, the temperature reached in the centre of the drum was insufficient to kill these spores.

DISCUSSION

Summarising the findings, anaerobic sporing bacilli of the clostridial group were isolated from one swab of the floor of the theatre-in-use, from the dust of the main corridor of the theatre suite, from the dust of the theatre-under-repair and its sterilising-room, from the plaster-hair, and from specimens of theatre talcum powder before and after autoclaving. All the plaster-hair specimens gave a very heavy and rapid growth of these organisms. Toxigenic strains of tetanus bacilli were isolated from all these sources except the theatre-in-use. Some of the other anaerobic bacteria were potential producers of gas-gangrene. Samples of sterilised silk, cotton-wool, and swabs from autoclaved rubber gloves were sterile.

Plaster-hair

Several sacks of hair were present in the theatre-under-repair. Because of its animal origin it was the most likely material to contain clostridial spores, and in fact did so. No other material was discovered in the theatre suite which, because of its nature or source, was likely to contain these spores. The plasterers pulled this hair apart and beat it with laths in the theatre-under-repair, thereby certainly contaminating the atmosphere and dust of that theatre. It was therefore concluded that the plaster-hair was the source from which the tetanus and other anaerobic bacteria were disseminated. In other words, had this hair not been admitted to the theatre, tetanus spores would probably not have been isolated from the other sources.

The plaster-hair which had been used was traced to the packers and processors, who stated that it was blended goat-hair obtained from tanneries in various parts of Britain, that the hair was pulled from skins which had been treated by the "lime and chemical" process, and that they believed that the hair used was from goat skins of Abyssinian origin. The implications of the use in industry of hair containing the spores of anaerobic organisms is being investigated separately.

Theatre Ventilation

It has been mentioned that the exhaust system of the theatre ventilation produced cross-currents within the theatre suite and would disseminate dust situated in one part of the theatre throughout the suite. Dust in the theatre-under-repair, contaminated with tetanus and other spores from the plaster-hair, could easily have been disseminated in this way. This would explain the finding of such bacteria in different parts of the theatre suite and in the talcum powder.

Ventilation systems of this type, introduced into operating-theatres during the last fifty years were designed to get rid of the steam from the sterilisers and in general to make the theatre comfortable for the staff—particularly the surgeon—to work in. Admirable though this purpose is, the problem of adapting the ventilation to suit the patient's needs, and in particular to minimise wound infection arising in the theatre, was not considered seriously until recently. Bourdillon and Colebrook[2] designed and introduced for the treatment of burns an air-conditioned dressing-station into which filtered, warmed, and humidified air was passed. The forced-ventilation plant used was designed "to ensure an atmosphere almost free from bacteria at the start of the dressings and to cause rapid evacuation of organisms disseminated through the air in the course of each dressing." The incidence of added infection due to hæmolytic streptococci, *Ps. pyocyanea*, and *Proteus* among the burned patients was greatly reduced after the introduction of this dressing-station.[3, 4] It is likely that the incidence of added infection in surgical wounds would equally decline if ventilation systems designed to control the hygiene of the air were generally introduced into operating-theatres. Moreover the dissemination of tetanus spores and the infection of two patients with tetanus, which gave rise to this present investigation, would not have happened. It may be argued, however, that the plant and theatre reconstruction required for the hundreds of operating-theatres in the country would be too costly. This argument is reminiscent of that used in Lister's time against the general introduction of expensive sterilising equipment into theatres. But autoclaves and sterilisers are now in general use, and no surgeon of the present day would operate with unsterile instruments or gloves.

Talcum Powder: the Vehicle of Infection

The presence of various clostridia, including *Cl. tetani,* in the autoclaved talc was considered highly significant. A similarly contaminated powder would probably have been used by the surgeon to dust his hands before gloving and was likely to have entered the patients' wounds. For this reason the talc is considered to have been the final vehicle of contamination with tetanus spores. Airborne dust containing tetanus spores cannot be excluded, but it seems a less likely vehicle of infection.

There are several lessons to be learnt from the unsterile though autoclaved talcum powder. First, talcum powder should be packed in small quantities, and the packets should be well separated from one another in the drum container; this will allow the easy removal of air during the autoclaving and the easy entry and circulation of superheated steam. Secondly, non-sterile talcum powder should not be used to dust rubber gloves, mackintoshes, &c., since these are normally autoclaved at only 5 lb. pressure to prolong their life; the dusting should be performed with talcum powder which has already been autoclaved at 20 lb. pressure. Finally, the efficiency of autoclaving should be bacteriologically controlled with a selected suspension of *Bact. subtilis,* in the most tightly packed drums.

SUMMARY

A bacteriological investigation into a hospital source of two cases of tetanus is described.

Building repairs were being done on part of the theatre suite, and here animal hair was being mixed with plaster powder. The hair gave a heavy growth of various strains of anaerobic sporing bacilli, including toxigenic strains of *Cl. tetani.* Some of the other strains produced experimentally muscle gangrene in guineapigs.
plaster hair is considered to have been the original sou
of the tetanus infection.

From dust or floor sweepings of various parts of t
theatre suite and from specimens of talcum powd
(glove powder) toxigenic strains of tetanus and oth
anaerobic sporing bacteria were isolated. This is thoug
to have been the result of dissemination of spo
containing dust originally contaminated from t
plaster-hair.

The dissemination was probably brought about
cross-currents of air in the theatre, and these w
produced by exhaust ventilation in the theatre suite.

Clostridial strains, including toxigenic *Cl. tetani,* we
isolated from talcum powder autoclaved at 20 lb. pressu
and ready for use. This imperfect sterilisation w
considered to have arisen from the tight packing of t
powder packets in the sterilising drum. The contaminat
talc (glove powder) was probably the final vehi
whereby tetanus spores reached the patients' wounds.

Some of the implications are discussed, and
recommendations on theatre ventilation and steri
of talcum powder are made. In particular the
installation into operating-theatres of plenum
ventilation systems designed to control the air h
of the theatre suite is advised.

I wish to thank Prof. J. C. Cruickshank, of the School of Hygiene, for confirming the identity of se
strains of *Cl. tetani*; to Mr. L. Nelson for technical assistan
and to my surgical colleagues for their cooperation
support.

NON-TRAUMATIC THROMBOSIS OF TH CAROTID ARTERY

SENIOR MEDICAL
REGISTRAR

THE QUEEN ELIZABETH HOSPITAL, BIRMINGHAM

TRAUMATIC thrombosis of the internal carotid arte
has been known since 1872, when Verneuil described
case with right hemiplegia and aphasia, which wa
attributed to direct cerebral injury until necropsy reveale
thrombosis of the internal carotid artery and its branche
Many other cases have been reported since, but n
cases of non-traumatic thrombosis had been diagnose
until Egas Moniz introduced angiography of the cerebra
arteries. In 1937 Egas Moniz et al. reported 4 cases o
non-traumatic thrombosis of the internal carotid arter
among 537 patients submitted to angiography. Fro
that time numerous cases have been reported fro
Germany, Scandinavia, and Portugal, the most notab
being 9 described by Andrell (1943), who collected 2
from the literature. Later Egas Moniz (1947) added 1
further cases when he published his monograph on this
subject; Taptas and Pecker (1948) reported 5 cases
and Wolfe (1948) collected 32 published cases and adde
1 of his own.

We describe here 6 cases of thrombosis of the intern
carotid artery, including 1 in which the common caroti
artery also was thrombosed—a condition which seems t
be previously unreported.

CASE-RECORDS

Case 1.—A man, aged 41, was admitted under Prof. Brod
Hughes on Aug. 1, 1946. In November, 1945, he had giv
a pint of blood as a donor. Four days later he complained o
headache and dizziness. One and a half hours after the ons
of the headache a friend walking home with him noted th
his speech was peculiar. Soon after reaching home the pati
lost consciousness and remained unconscious for three wee
A right hemiplegia was found, and on regaining consciou
three weeks later the patient had dysphasia. Lumbar punc

1—Occlusion of internal carotid artery in its intracranial course, showing irregularity lumen. Branches of external carotid artery are well shown and seem to be larger in normal. (Case 2.)

ie day of onset produced a much bloodstained cerebro-l fluid (C.S.F.). Six weeks after the onset power began to n in the right leg and arm.

giography.—On Aug. 6, 1946, arteriography, through the ion carotid artery at the level of the cricoid cartilage, ed no filling of the internal carotid, but all the branches e external carotid were shown.

gress.—Ten months later, when seen in the outpatient tment, the patient had improved in his speech and could well, though there was little change in physical signs. years after the original trouble his speech was normal, is hemiparesis was still present.

se 2—A man, aged 57, was admitted under Prof. P. C. P. e on April 16, 1948. Fifteen months previously a weak-of the right leg had developed; this had improved but was still present. nth before admission he noticed weak-of the right arm and numbness down the surface of the same forearm, followed ek later by numbness of the right side e face. Five and a half years before d had an attack of coronary occlusion here had also been intermittent claudica-n both legs.

examination he had a motor and sensory hasia, and a right hemiparesis in which ace was also involved, with impairment rtical sensation on the right half of the . Examination of the fundi showed the edges to be slightly blurred, the veins rged, and the arteries small. There no pulsation in the dorsalis pedis and iteal arteries of either leg. The blood-sure was 180/95. Lumbar puncture luced C.S.F. under a pressure of 105 mm., a normal rise and fall on jugular com-sion, and normal cytology and chemistry. tro encephalography showed gross abnor-ity, greatest in the left frontal region. The ssermann reaction was negative.

ngiography of the left common carotid April 25, 1948, showed very good filling the external carotid circulation. The rnal carotid was filled as far as its bifurca-into the middle and anterior cerebrals, the lumen of the vessel in its intra-nial portion was very much narrower than normal and varied considerably in different parts. In its intradural portion the artery was straightened and appeared to end abruptly, but there was some filling of the sylvian group, and the appearances suggested a lesion of the wall of the artery in its intracranial portion, with partial occlusion. These appearances might represent canalisation following thrombosis. Angiography was repeated twice and the same result obtained (fig. 1).

Case 3.—A man, aged 58, was admitted under Dr. Ernest Bulmer on June 25, 1948. In May, 1948, his wife had noticed that he was dragging his right foot. Next day his right arm became weak. A month later a transitory speech defect developed, which soon passed off but was superseded in a week by a severe dysphasia, which persisted until admission.

On examination the patient could not speak properly, the most constantly reiterated sound being ' no " The left pupil was smaller than the right and did not react to light, he was blind in this eye. The left central retinal artery was thrombosed. There was a right hemiparesis affecting face, palate, and tongue, in addition to the extremities. The blood-pressure was 150/100. Peripheral arterio-sclerosis was present. The serum Wassermann reaction was negative. Lumbar puncture produced C.S.F. under a pressure of 100 mm., with normal cytology and chemistry.

Angiography of the left common carotid artery on July 6, 1948, showed filling of the external carotid artery system only. To confirm internal carotid thrombosis, the carotid bifurcation was exposed; though there was normal pulsation in the external carotid, there was very little pulsation in the internal carotid at its origin. A needle was introduced into the internal carotid artery just above the bifurcation and 'Uriodone' was injected. Again only the external carotid circulation was shown. A clamp was applied on the external carotid artery, and 8 ml. of uriodone was injected into the internal carotid artery. This time no dye appeared in either the internal or the external carotid system, suggesting that the left internal carotid artery was blocked just above the level of injection (fig. 2).

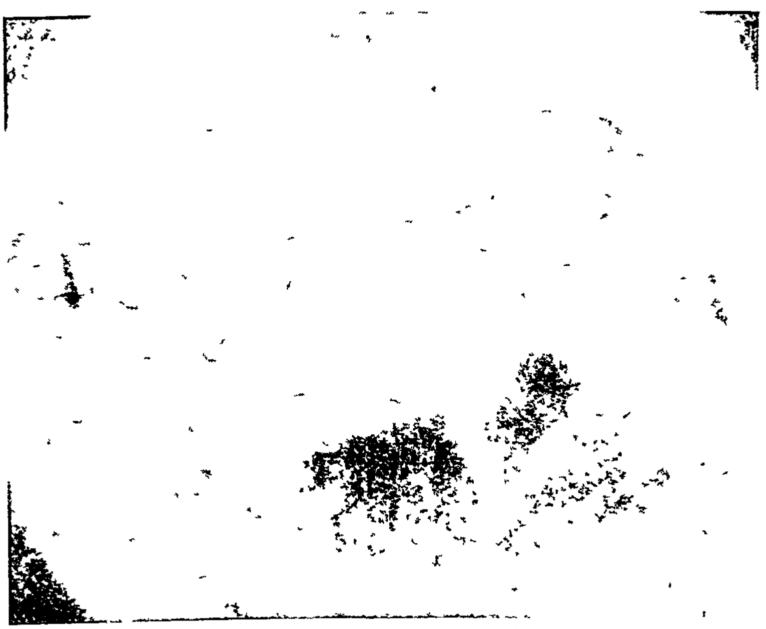

Fig. 2—No filling of internal carotid artery. Branches of external carotid are well shown. (Case 3.)

Case 4.—A man, aged 51, was admitted under Mr. J. M. Small on July 10, 1948 In 1942 he had begun to have increasing weakness and numbness of the right arm, which progressed until 1945 and then remained stationary. Towards the end of 1943 he had a "fainting attack" lasting a few minutes. From that time he had one of those attacks every two or three months. In 1944 he began to have difficulty with his speech. He could read and write but could not remember the words he wanted to say. His only other complaint was that he walked like a drunken man.

On examination there was no papillœdema. There was a right upper-motor-neurone facial weakness. There was clumsiness of the right hand but otherwise no weakness of the extremities. The Wassermann reaction of the blood and C.S.F. was negative. Lumbar puncture produced C.S.F. under an initial pressure of 110 mm., with normal cytology and chemistry.

Pneumo-encephalography (July 15, 1948) showed large subarachnoid spaces suggesting generalised cerebral atrophy, more extensive on the left side.

Electro-encephalography showed a considerable abnormality on the left side, with some evidence of a focus of abnormality in the posterior parietal region.

Angiography.—On July 20, 1948, the left common carotid artery was exposed for the purpose of angiography. The artery was much harder than normal and felt like a solid cord. There was no expansile pulsation, but a vertical movement of the artery synchronous with the pulse was noted. A needle was introduced into the artery, but no blood was obtained, and on removing the needle from the artery there was no bleeding. As the artery was followed upwards the transmitted vertical movement became less obvious, whereas when the artery was followed downwards the movement became more obvious. At this stage an assistant, asked to feel the temporal pulsation, could feel none. When the face was uncovered it was seen that, though on the right side the temporal artery was enlarged and pulsating, on the left side no vessel was visible. Angiography of the right common carotid was then performed, and this showed normal internal carotid vessels on that side; some of the radio-opaque substance had also passed into the left anterior and middle cerebral arteries.

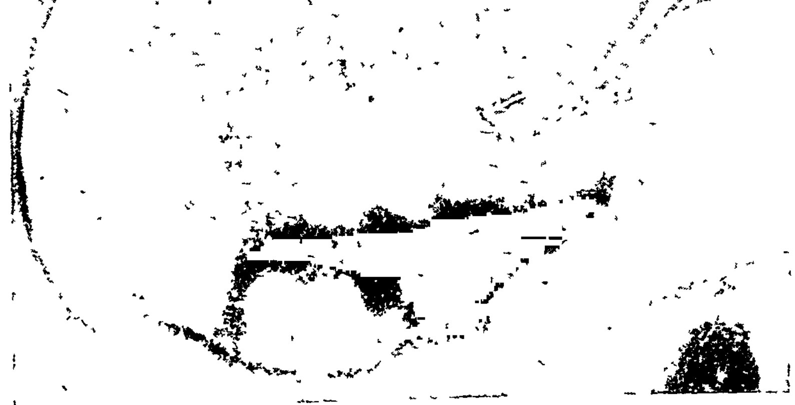

Fig. 3—Internal carotid artery very irregular and much narrower than normal. Sylvian group of vessels not well filled. Branches of external carotid artery all filled and much larger than normal. (Case 5.)

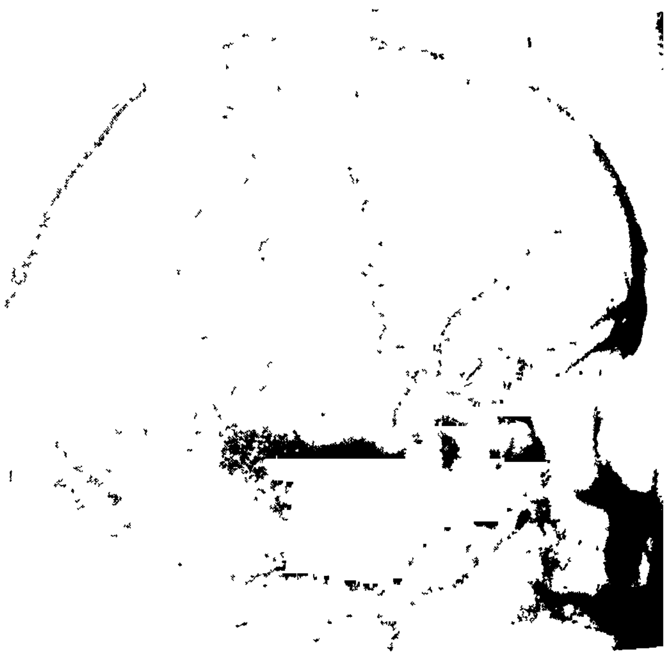

Fig. 4—Intradural part of internal carotid artery narrower than normal, straighten and ending abruptly. External carotid branches well shown. (Case 6)

Case 5.—A man, aged 48, was admitted under Mr Sm
on July 27, 1948. Fifteen weeks before admission he had
a cramp-like feeling in his left foot; this spread up to his
and trunk, and then into the third and fourth fingers of
left hand. Eleven weeks before admission he noticed that
was dragging his left foot, and then his arm and hand beca
weak. About eight weeks before admission the left side of
face was also involved.

On examination he had a left hyposmia. There was a
hemiparesis affecting the face as well as the extremities. Th
was increased tone on the left side of the body. All the tend
reflexes on the left side were increased, and the left plan
response was extensor.

Angiography (fig. 3) of the right common carotid (July
1948) showed that the internal carotid artery was very m
narrower in its intracranial portion and had an irregu
lumen. The middle cerebral vessels were shown, though
well filled. The external carotid branches
much larger than normally seen in comm
carotid angiography.

Ventriculography (Aug. 4, 1948) showed th
pressure was normal and there was
deformity of the ventricular system
patient's condition was thought to be due
incomplete thrombosis of the internal caro
artery.

Case 6.—A man, aged 57, was admit
under Mr. Small on Dec. 4, 1948. In 1
he had noted a tendency to catch his right f
while walking. Two months before adm
a tingling sensation developed over the ri
half of his body. No weakness of the hand
arm was noted, but there was a tendency
drop objects held in the right hand.

On examination a slight right facial we
ness was found; the motor power of the ri
arm and leg was diminished, though the t
was not increased. Tendon reflexes w
brisker in the right arm than in the l
The right plantar response was exten
Coordination of movements of the right ha
and right leg was impaired. The Wa
mann reaction was negative. Lum
puncture showed a clear fluid under 110
pressure, with normal rise and fall
normal cytology.

Pneumo-encephalography (Dec. 13, 1948
no evidence of shift or deformity of the lat
ventricles. The subarachnoid spaces w

giography of the left common carotid (fig. 4) showed wing of the internal carotid artery in its intradural n, which came to an abrupt end at the point of its ation into the anterior and middle cerebral arteries. narrowed intradural portion of the artery was also mally straight. There was very good filling of the nal carotid circulation, and vessels of the scalp were on hole larger than seen in normal angiography.

ÆTIOLOGY

ncidence

ut of 33 cases of thrombosis known to have affected internal or the common carotid arteries (Andrell , Egas Moniz 1947, Wolfe 1948), as opposed to ler vessels, only 5 have been in females.

incidence

the 33 cases under review the age-incidence in rent decades was as follows: 1 case in the second de; 4 cases in the third: 2 in the fourth; 11 in fth; 14 in the sixth; and 1 in the seventh.

were on the left and 9 on the right.

ation

rombosis of the common and internal carotid ries has probably been diagnosed in the past as bral thrombosis, indicating thereby thrombosis of smaller cerebral vessels. It is only with the advent erebral angiography that the affection of the larger els has been recognised. There is no reason to suppose the ætiology of the two conditions differs greatly, gh in the limited series under review the pre- erance of cases in males and the greater inci- e on the left side differ from cerebral thrombosis softening, which is usually considered to occur lly between the sexes and between the two s of the brain (Jones 1909). As vessels of a larger re are involved, circulatory changes commonly ribed in medical textbooks, such as slowing of the lation in old age, and increased viscosity of the d in polycythæmia, probably play a lesser part, eas changes in the vessel wall are more important g., trauma, atheroma, syphilis, arteriosclerosis, mbo-angiitis obliterans, temporal arteritis, poly- itis nodosa, and aneurysm of the cerebral vessels.

gas Moniz (1947) says: “In the ætiology of carotid mbosis syphilis stands out as the most important, is followed by alcoholism, arteriosclerosis, and ctions (enteric fever, &c.), Buerger's thrombo-angiitis terans. traumatism, &c.” But it is difficult to agree h the order of importance of the ætiological factors n by Egas Moniz, who himself only mentions 1 case h a history of syphilis (but the Wassermann reaction hat case was negative). None of the 6 patients reported re had a positive Wassermann reaction or a history yphilis.

orgo (1939) believed arteriosclerosis to be the most ly cause of thrombosis of the internal carotid ry, and in at least 2 of our patients this seemed be so.

s regards thrombo-angiitis obliterans, case 2 had a tory of intermittent claudication, but the condition s probably not thrombo-angiitis obliterans but athe- ma, which also involved his coronary arteries. Sorgo cribes thrombo-angiitis obliterans in 1 case of throm- sis of the internal carotid artery, but arteriosclerosis as also present. Hausner and Allen (1938) found evi- nce of cerebral lesions in 2% of 500 cases of peripheral rombo-angiitis obliterans. Davis and Perret (1947) fer to 11 patients with cerebral thrombo-angiitis bliterans, 9 of whom underwent operation. Only 3 of hese 11 had evidence of peripheral circulatory disturb- nce, and, so far as can be judged from the report, none f them had thrombosis of the internal carotid artery. rof. Hilding Bergstrand, reporting on a section of the internal carotid artery from one of Andrell's (1943) cases, stated that the pathology was not unlike that of Buerger's disease, but there was no thickening of the intima.

Polyarteritis nodosa and temporal arteritis have played no part in the cases described above, but possibly, as these conditions become more widely recognised, they may prove to be of some ætiological importance. Professor Bergstrand, in a report on another case, stated that there was considerable inflammatory infiltraiton of round cells and leucocytes in the adventitia and periarterial tissue, but despite this he did not consider the picture to resemble that of polyarteritis nodosa.

Aneurysm could be a cause of thrombosis either by direct extension of the contained clot into the internal carotid artery or by pressure of the aneurysm on the artery. This may well have been the cause in case 1, where the presenting picture was one of subarachnoid hæmorrhage.

Trauma has not been considered here, but it is well to mention in passing that traumatic thrombosis may develop as a result of injuries varying from a punch on the jaw to a gunshot wound of the neck. The thrombosis may develop from a few hours to a few weeks after the injury (Caldwell 1936).

PATHOLOGICAL BASIS OF SYMPTOMS

Symptoms arising from thrombosis of the internal carotid artery contrast with those due to ligation of the artery. In the case of internal carotid ligation there is usually no disturbance at all, or there may be slight hemiparesis from which the patient often recovers with no further incident. In some patients, however, rapid and complete hemiplegia develops within a few minutes of the ligation of the artery. Thrombosis of the carotid artery, on the other hand, is characterised by repeated minor pareses or attacks of dysphasia during the early stages; these cannot be explained by thrombosis and recanalisation, because they are too transient. Accordingly it has been suggested (Andrell 1943) that the attacks are due to nervous impulses arising in the wall of the diseased carotid artery and causing vasospasm of the cerebral vessels. Treatment by removal of a portion of the internal carotid artery and by cervical sympathectomy is based upon this concept.

SYMPTOMS

The first symptom is often some transient weakness of one of the extremities, usually on the right side, associated sometimes with a minor disturbance of speech. Partial recovery usually takes place, and there ensue several recurrent exacerbations of weakness and disturbance of speech culminating in a dramatic incident with increased weakness, aphasia, loss of consciousness, or visual defect, leading the patient to come for treatment. Headache does not seem to be a prominent symptom. The interval between the initial episode and the major incident varies from a few hours to many years—e.g., case 1, $1^{1}/_{2}$ hours; case 6, 2 years; case 4, 6 years. It is suggested that slighter episodes are due to spasm of the smaller cerebral vessels consequent on nervous impulses originating in the diseased wall of the internal carotid artery, and the major episode is due to either complete or incomplete thrombosis of the main trunk. It is most interesting to note that in only one of our cases thrombosis had occurred on the right side, all the other lesions being on the side of the dominant hemisphere. This peculiar lateralisation of thrombosis has been noted in other cases reported. For instance, of the 23 cases collected by Andrell (1943) 16 were on the left side. This is in contrast to thrombosis of the smaller cerebral vessels, since Jones (1909) in 372 cases of cerebral thrombosis and softening found the lesion in 176 on the right and 196 on the left, an approximately equal incidence.

Hemiparesis varies from slight unsteadiness or inability to perform fine movements of the hand to complete hemiplegia, and dysphasia varies from a slight degree to complete aphasia. In one of the cases reported above the eye on the affected side was blind, owing to thrombosis of the central retinal artery.

In some cases there is definite improvement in the condition after a time, as in our case 1, which has been followed more than three years; the patient's speech has improved considerably, and though he is still hemiparetic he can walk about. In most of the reported cases the condition has remained stationary for years.

SIGNS

Central Nervous System

Most of the patients were rather euphoric. Hyposmia was noted in 1 case, and Egas Moniz (1947) has also mentioned anosmia as not uncommon. Papillœdema has occasionally been observed, but on the whole it has been rare. Homonymous hemianopia from cerebral thrombosis, or total blindness due to thrombosis of a central retinal artery, may be present. Facial weakness of upper-motor-neurone type is common. A few patients have complained of noises in the ear without any evidence of deafness. Hemiparesis, with sensory involvement of cortical type, may affect the face, arm, and leg in an unequal degree.

Cardiovascular System

One of the patients had no pulsation in the dorsalis pedis and posterior tibial arteries, as a result of a peripheral vascular lesion. Another had generalised arterial disease. None of the 6 had much hypertension, the highest blood-pressure recorded being 180/95.

Lumbar Puncture

The pressure of the C.S.F. was usually normal or subnormal, with normal biochemistry and cytology, except in case 1, where the C.S.F. was grossly bloodstained.

Pneumo-encephalography

This showed either a normal ventricular system or a slight enlargement of the ventricle on the side of the lesion, with large subarachnoid spaces.

Angiography

This is the most important diagnostic measure. It is safely and simply done, usually under local anæsthesia. Angiography of the common carotid artery is most suitable, because it will show absence of circulation or partial block of the internal carotid as well as increased size of the external carotid branches. The percutaneous technique (direct injection into the artery without exposing the vessel) is popular at present, but in case 4 direct exposure of the artery showed its pathological condition.

The commonest site of thrombosis in reported cases seems to be either the point of bifurcation of the common carotid artery or a centimetre or two above the bifurcation. Of our 6 patients 1 had complete thrombosis of the carotid artery, 2 had thrombosis just above the bifurcation, and 2 had a lesion of the intracranial portion of the internal carotid artery, shown by its straight course, the irregularity of the wall, and the narrowing of its lumen. Though the vessels appeared to come to an abrupt end, some radio-opaque substance had passed into the branches of the middle cerebral artery, suggesting incomplete thrombosis. Finally, in 1 case there was much tortuosity, narrowing, and irregularity of the lumen of the internal carotid artery in its intracranial portion. In all our cases (especially no. 5) the external carotid branches were dilated. This has also been noted by other workers.

Though cerebral vascular lesions were suspected in 2 cases, a diagnosis of carotid thrombosis could not have been confirmed without angiography. In 1 case careful
palpation of the common, internal, and temporal br
of the external carotid artery would have given
diagnosis, which was ultimately made on direct e
of the common carotid artery. In making a diagnosi
internal carotid thrombosis with the aid of angiogra
certain precautions are necessary. Occasionally,
performing angiography in patients with some o
intracranial lesion, one finds incomplete filling of
internal carotid artery, most commonly somewher
its intracranial course. This is usually due to fa
technique. In the present 6 cases repeated injec
were given, and, when there was no filling of the inte
carotid at all, the bifurcation of the common ca
artery was exposed to confirm the diagnosis, as in ca
Where it is suspected that the thrombosis is in the cer
rather than the intracranial portion of the artery
should take care to ensure that the X-ray plate incl
the region of the bifurcation of the common ca
artery. In case 6, where the left internal carotid
thrombosed, vertebral angiography was also done
showed that the left posterior cerebral artery was
larger than the right, probably in compensation.
case 4, with complete thrombosis of the common ca
artery on the left side, angiography was done o
opposite side and showed increased vascularity
filling of some of the vessels on the side of the lesio

TREATMENT

Treatment does not differ widely from that of
paresis in cerebral thrombosis, and conservative
ment is usual. Riechert (1938) removed a portion
artery to abolish abnormal impulses reaching its
cranial branches, but the results were not encoura
Wolfe (1948) states that periarterial sympathect
cervical ganglion sympathectomy, resection of
common carotid artery with the adjoining portion
external and internal carotid arteries, and excisi
the thrombosed part of the artery have all been tried.
use of heparin and dicoumarol are contra-indicat
cerebral vascular lesions because of the possibili
cerebral hæmorrhage.

SUMMARY

Six cases of thrombosis of the carotid artery in dif
degrees, from partial thrombosis in the intrac
portion of the internal carotid to complete thro
of the common carotid artery, are described. Æti
symptoms and signs, methods of investigation,
diagnosis are discussed.

Our grateful thanks are due to Professor Cloake, Dr. B
Prof. Brodie Hughes, and Mr. Small for permission to p
cases admitted under them, and to Dr. Black for perm
to publish the X rays as photographs.

SEASONAL VARIATIONS IN THYROTOXICOSIS

l. E. Morgans
B. Lond., M.R.C.P.
ASSISTANT

W. R. Trotter
D.M. Oxfd, M.R.C.P.
LATE ASSISTANT

L UNIT, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

ORDS of the date of admission to hospital and of te of onset of symptoms both suggest that thyrois begins more often in the spring or summer it other seasons (Rusznyak 1922, Oehme and 1930, Hirsch 1930, Iversen 1948, Jacobowitz

Evidence of this sort may be fallacious, for s are not necessarily admitted to hospital at a tage of their disease, and they may forget or miset their symptoms. Long-term treatment with i-thyroid drug provides an opportunity of obtainre satisfactory data, since the patients are under bservation for long periods and any increase in hyrotoxicosis is immediately obvious, since larger ire required to control the symptoms.

INVESTIGATION

rvations have been made on 122 patients with oxicosis (118 with diffuse goitre and 4 with nodular treated with methyl thiouracil. For the first veeks of treatment the patients were in hospital; ter they attended monthly as outpatients while treatment, or at longer intervals when no drug eded. The present data were obtained from the ent records. Progress has been assessed from nical findings and the changes in body-weight ilse-rate. When the patient is seen repeatedly same observers, these data are sufficiently accurate ictical purposes. Anti-thyroid drugs were first ere in 1943, but the records of the early period, xperience was being gained, have been discarded, ie present report refers only to outpatients ng between June, 1945, and June, 1949.

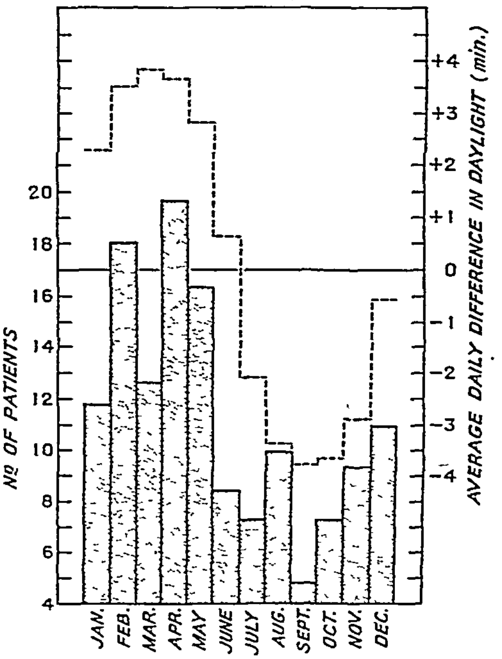
RESULTS

) of the 122 patients the dose of methyl thiouracil luced by gradual stages. These 59 patients showed lence of thyrotoxicosis while under treatment or nently, and it was therefore never necessary to e the dose. In these patients thyrotoxicosis parently become progressively less from the time ent was started, and if any seasonal variations were present they were obscured by the patients' uninterrupted progress towards recovery.

UTION BY MONTHS OF OCCASIONS ON WHICH AN INCREASE OF DOSE WAS NEEDED

nth	No. of patients needing increased dosage	No. of patients per 28-day month	Difference from mean monthly value
..	13	11·8	+0·5
..	18	18·0	+6·7
..	14	12·6	+1·3
..	21	19·6	+8·3
..	18	16·3	+5·0
..	9	8·4	−2·9
..	8	7·2	−4·1
..	11	9·9	−1·4
ber ..	5	4·7	−6·6
..	8	7·2	−4·1
ber ..	10	9·3	−2·0
ber ..	12	10·9	−0·4

In the other 63 patients unmistakable signs of thyrotoxicosis appeared at one time or another, either while they were still taking methyl thiouracil or after completion of a course of treatment. When this happened, the dose of methyl thiouracil was increased or a fresh course started. Usually the symptoms were soon controlled, and the dose was reduced again after a few months; in many cases exacerbations were only temporary events in an otherwise favourable progress. The accompanying table and figure show the number of these 63 patients needing an increase of dose in each calendar month during the four-year period. The figures have been corrected for varying lengths of month and are shown as the number which would have occurred in a 28-day month. In each of the first five months more patients needed an increase of dose than would be expected if the distribution were uniform throughout the year; in each of the last seven months fewer patients needed an increase of dose. David's (1947) test shows that, with a χ^2 of 20·6, this particular sequence would occur by chance much less often than 1 in 100 times.



Seasonal variation in daylight compared with number of patients on methyl thiouracil requiring increased dosage, arranged in months of the year: stippled columns, patients per 28-day month needing extra dosage; interrupted line, change in amount of daylight.

These data are derived from a particular type of patient —i.e., those who have had exacerbations of thyrotoxicosis during treatment. Analysis of the time of year at which patients have been able to dispense with treatment, without an immediate recurrence of their symptoms, suggests that most cases of thyrotoxicosis are in some way susceptible to seasonal influences. In the present series methyl thiouracil was discontinued whenever a patient had been symptom-free for three months on the lowest dose (25 mg. daily). At first sight it seems unlikely that this rather arbitrary procedure would have any constant relation to the time at which a remission actually occurred. However, when the times of stopping methyl thiouracil are plotted by calendar months, a surprisingly clear relationship to the seasons emerges. In over 60% of the cases the drug was discontinued in the four months October–January, both in those who had exacerbations and in those who made an uninterrupted recovery. This type of evidence is difficult to interpret and may not have much significance, but it is mentioned here because it leads us to suspect that seasonal variations in the intensity of thyrotoxicosis may not be confined to one particular class of patients.

DISCUSSION

The interrupted line in the figure shows the mean increase or decrease in the daily duration of daylight during each month, compared with the previous month. Since there is a good correlation ($r = 0{\cdot}83$, S.E. $= \pm 0{\cdot}30$) between the changes in the length of daylight and the numbers of exacerbations of thyrotoxicosis, it can be inferred that these are in some way connected. A reasonable assumption would be that length of daylight is one of the factors determining, directly or indirectly, the spontaneous variations in severity which have often been observed in thyrotoxic patients. But it would be a mistake to base any detailed argument on this correlation. It is highly probable that our data have a seasonal pattern; but the precise arrangement of that pattern might be partly accidental.

In normal persons basal metabolism tends to reach a peak during the spring (Brody 1945, Fitt 1941). This may well indicate a spring-time increase in thyroid activity. It is tempting to suggest that increasing length of daylight, which is known to stimulate the output of gonadotropic hormone by the anterior pituitary in several species of mammals and birds, can also stimulate the output of thyrotropic hormone. Man is certainly not altogether immune to seasonal influences; the growth-rate of children (judged by increase of weight) is greatest in the autumn and least in the spring; and even in the psychological sphere the spring-time peaks in suicide-rate and juvenile-delinquency rate suggest that changes in the length of daylight can indirectly affect emotional tone (Fitt 1941).

An alternative explanation may lie in the fact that some common foodstuffs contain a substance capable of inhibiting the production of thyroxine by the thyroid gland (Greer and Astwood 1948). The amount of this substance in the diet may vary at different seasons. It is known that cabbage picked in the early winter is more goitrogenic for the rabbit than cabbage picked at other times of the year (Webster et al. 1931). If other foodstuffs vary in a similar way, the net effect might be sufficient to control thyrotoxicosis in the autumn but not at other times of the year.

On the available evidence both of these suggestions appear about equally probable. Since our data are derived from a small number of cases, further confirmation of the facts is clearly needed; and it would be interesting to know whether similar seasonal variations occur in patients living in other latitudes and on other diets.

SUMMARY

In a group of patients treated with methyl thiouracil and under close observation throughout the year, exacerbations of thyrotoxicosis were found to be most frequent in the spring and least frequent in the autumn. This may be a direct effect of changes in the duration of daylight or an indirect effect of variations in the amount of goitrogenic substances in the diet.

ELECTRIC-BLANKET TREATMENT RHEUMATOID ARTHRITIS

ERIC FRANKEL
M.D. Lond., M.R.C.P.
PHYSICIAN, WANSTEAD HOSPITAL, LONDON

IN the treatment of rheumatoid arthritis many a have been made to increase the blood-supply affected joints by various means, such as spinal pu transfusions of blood and plasma, intravenous injections, radiant heat, wax baths, and short diathermy. These methods are usually applied o short periods, and their beneficial effects are pondingly short-lived. What seemed to be re was a means of applying heat to the body which be well tolerated by the patient and would p sustained vasodilatation. The method adopted application of a large electric blanket to the low of the body.

The patient's feet, legs, and pelvis are well pr with sheets of cotton-wool bandaged to the lim body. The electric blanket is next wrapped rou lower half of the patient's body and kept in p with bandages. The blanket is left in position fo periods—4 weeks in some cases—and the patient taken out of it for toilet purposes. The temp between the cotton-wool and the skin is take charted every 4 hours and it is kept at 110 This type of application of heat produces gene vasodilatation with pronounced sweating. The re loss of fluid and salt is made good by additional The fluid intake and output of urine are charted a amount of chloride excreted in the urine is recorde

RESULTS

The patients tolerate this treatment well. Th hot and perspire profusely, but there are no constitutional disturbances. There is slight pyre temperature varying between 99° and 100°F, a pulse-rate is slightly increased. The patients however, a sense of general well-being, their app good, and they gain weight. They find the treatment very comforting and are definite abo loss of pain and improvement in the stiffness and i in the range of movement of the affected joints erythrocyte-sedimentation rate usually showed a fall of 5–10 mm. In no case was a rise observed. counts remained essentially unchanged, apart from improvement in anæmic patients; there was no cytosis as a result of the treatment. There w changes in the radiological appearance of the s bones before and after the treatment, but sof swellings were reduced. The patients were give diet and added vitamins—i.e., ascorbic acid and vit complex in tablet form—but no other treatm given while the patients are in the blanket.

In the last 18 months fourteen patients hav treated. Eleven of these had advanced rheu arthritis with severe joint deformities and much lim of movement, and three were moderately severe cas were in the blanket for 1 week, seven for 2 weeks for 3 weeks, and two for 4 weeks.

In every case there was striking improvement the first week of treatment; the range of moveme increased, the swellings subsided to a large exte the stiffness and pain were considerably relieved. women whose hands had been fixed for 5 year able to knit again after 3 weeks' treatment.

COMMENTS

Though improvement in these cases appears t been maintained, it is impossible to say at thi whether further relapses may occur; it is th suggested that the method should be tried at a centre on a larger series of patients who could be f fully. To me, the electric-blanket treatment o be more promising than any other measures t is now possible to apply in this country. An ial advantage is that it can be given in the s home under the supervision of his own doctor. ld be used in patients with early rheumatoid s and during relapses; the crippling effects of ase might then be prevented. For a moderately case, 2 weeks' treatment seems to give the m benefit.

electric-blanket treatment should also be tried entally in conjunction with other measures for ng the blood-supply to the diseased joints—e.g., sions of plasma and blood, nicotinic-acid infusions, ylammonium bromide, gold or vaccine therapy, ocopherol (vitamin E).

electric blanket is a clumsy device for applying ous heat, because it severely restricts leg move- Mr. D. Lang Stevenson, F.R.C.S.E., has suggested ousers covering the feet should be made out of blanket material. Such an appliance could sily be kept in position and would allow nursing n and movement of the legs. If it is to be applied nts in their homes the appliance must be absolutely roof and safeguarded against short-circuiting and . In view of the sweating it will produce, the ce itself should not be padded but should be over the protecting cotton-wool which can be l as required. One should also be able to regulate perature inside the blanket by means of a variable stat.

Q FEVER

REPORT OF A CASE

W. G. MANDERSON
M.B. Glasg., F.R.F.P.S.
RESIDENT PHYSICIAN, HAM GREEN HOSPITAL, BRISTOL

VER was the name given by Derrick (1937) to le febrile illness occurring among slaughter-house s in Queensland, Australia. Burnet and Freeman showed that the organism recovered from these s was a rickettsia. The organism is known as *ia burneti.*

recently Q fever was considered to be of little nce except to certain communities in Australia. petros (1949) isolated a strain of *R. burneti* in 1944 an outbreak of an influenza-like illness in Athens, and in 1945 outbreaks of atypical pneumonia among roops in Greece and Italy were investigated by several and shown to be due to Q fever. The causal organism, ti, was isolated by Robbins et al. (1946). and Caughey dgeon (1947) presented serological evidence that an k of atypical pneumonia, previously reported by et al. (1946), was one of Q fever. Cheney and Geib identified the disease in Panama, and Topping et al. and Shepard (1947) reported outbreaks in the U.S.A. (1947) produced evidence of Q fever in Germany, and 948) described a small familial outbreak in Switzerland.

ew of the wide distribution of Q fever in the New World, Stoker (1949) looked for this disease at Britain and discovered Q-fever complement- antibodies in three patients who had had attacks pical pneumonia. Two of the patients had never verseas. These findings were regarded as evidence Q fever occurs in the British Isles. Harman (1949) scribed an outbreak of Q fever in a London hospital MacCallum et al. (1949) have isolated *R. burneti* the blood of one of the patients, thus proving sively that Q fever does occur in Great Britain. e following case-record describes an illness considered Q fever and probably contracted in the Bristol area.

CASE-RECORD

adio engineer, aged 22, was admitted on May 12, 1949, m Green Hospital, Bristol, as a case of primary atypical monia.

He had first felt unwell on May 2, 1949, when he was tired and unaccountably depressed. On May 5 he developed frontal headache, which gradually became severe. The headache occurred in bouts of moderate intensity and was most severe on sudden movement. On one occasion the patient stood up quickly and collapsed with sudden severe frontal pain. His appetite failed and he was very constipated.

On May 9 he consulted his doctor because these symptoms persisted and it was discovered that his temperature was 103°F. No cause for this pyrexia was discovered. On his doctor's advice the patient then went home to bed. During the night he suffered drenching sweats. On May 10 he developed a slight cough and noticed three small red spots on the skin of his abdomen. A sample of blood was sent to the laboratory for Widal testing. His temperature remained raised (103°F). On May 11 his cough became the predominant symptom. His sputum was blood-streaked and he complained of a dull ache over his right lower ribs anteriorly, made worse by deep breathing. His temperature was 100·4°F. On May 12 he had a frank hæmoptysis of bright-red blood. Since the illness had not responded to adequate dosage with 'Sulphamezathine' (30 g.), he was admitted to hospital for further investigation.

Past History.—Before the present illness he had always been healthy except for two attacks of pneumonia in childhood. He had been in the Royal Navy during the war but had not served overseas. He had had one injection of T.A.B vaccine in June, 1947.

Examination on Admission.—He was alert, intelligent, and of good physique. His general condition was good, and he was not unduly worried by the hæmoptysis. His temperature was 98·6°F, his pulse-rate 90, and respirations 20 per min. No skin lesions were noted. The tongue was covered with a white fur, but the fauces and tonsils were normal. The left tonsillar gland and axillary glands were palpably enlarged. On respiration there was diminished movement of the right lower ribs. The percussion note was diminished over the right lower zone. Over this area the respiratory murmur was bronchial in type and numerous "sticky" râles were heard. The spleen was easily felt during deep inspiration, the tip being two finger-breadths beneath the costal margin. The pulse was regular in rate and rhythm; the blood-pressure was 120/80 mm. Hg. The heart was not enlarged, and the heart sounds were pure and of good quality. No abnormality was found in the central nervous system. Auroscopic and ophthalmoscopic examinations were negative. Radiography of the chest revealed a clearing consolidation in the right mid-zone. The total leucocyte-count was 13,400 per c.mm. (polymorphs 73%, lymphocytes 20%, monocytes 6%, eosinophils 1%). The predominant organisms in the sputum were pneumococci; the tubercle bacillus was not found. Chemical and microscopical examination of the urine revealed no abnormality and culture was negative. The Widal reaction was suggestive of an anamnestic reaction, due to a previous T.A.B. inoculation. A test for cold agglutinins was negative.

Progress.—The patient, from the day of admission to hospital, felt well and did not need special treatment. His temperature, pulse, and respiration-rate remained normal throughout his stay. Hæmoptysis continued until May 15, and then stopped as suddenly as it had begun. The spleen could not be felt on May 16. By May 19 the physical signs of pneumonia in the right lower zone had disappeared, but the moist sounds previously noted in this area persisted. On May 23 radiography of the chest showed that there had been further clearance of the consolidation in the right mid-zone. The total leucocyte-count was 12,800 per c.mm. (polymorphs 73%, lymphocytes 23%, monocytes 2%, eosinophils 2%). On June 2 radiography of the chest showed no lesion. The physical signs in the right lower zone had disappeared, and the patient was discharged from hospital.

COMPLEMENT-FIXATION TESTS WITH Q-FEVER ANTIGENS

Dr. M. G. P. Stoker, of the department of pathology, University of Cambridge, examined samples of the patient's serum for Q fever. The technique described by Stoker (1949) was used for this investigation. The specimens of sera were obtained 26 and 39 days after the onset of the illness.

The titre of Q-fever complement-fixing antibodies was 1/80 in both specimens. Dr. Stoker considered this titre diagnostic of Q fever. Since the first specimen was obtained over three weeks after the onset of the illness, a rise in titre was not to be expected.

COMMENT

The patient's illness closely resembles Q fever in its sudden onset, high fever, severe persistent headache, lassitude, malaise, anorexia, and drenching sweats. Respiratory signs and symptoms in Q fever are usually described as minimal, and a pneumonitis is discovered on radiography in 60% of cases. The respiratory features vary. Hæmoptysis is described, though blood-streaking of the sputum is commoner. Many cases have been described in which the physical signs of pneumonic consolidation have been detected. Enlargement of the spleen has been reported in various outbreaks. In the present case the total leucocyte-count was higher than that usually reported, but this finding does not exclude the diagnosis.

Huebner et al. (1949), in a review of the clinical findings in 625 cases of Q fever, state that a high titre in the specific complement-fixation test, associated with a previous illness consistent with what is known about the disease, suggests Q fever. On these grounds the diagnosis was made in the present case.

An attempt is being made to trace the sou
infection in this case by serological investigation.

I wish to thank Dr. M. G. P. Stoker for the comp
fixation tests and for his help in the preparation o
report; and Dr. F. G. Jenkins for the clinical histor
patient before admission to hospital.

Medical Societies

ROYAL SOCIETY OF MEDICINE

The Tonsil and Adenoid Problem

AT a meeting of the section of laryngology on Dec. 2, with Mr. R. D. OWEN, the president, in the chair, the discussion was opened by Prof. R. S. ILLINGWORTH, who said that the *Index Medicus* recorded over a hundred entries under "Tonsils and Adenoids" every year. Writers on this subject must get away from "clinical impressions" and try to distinguish the results of careful surgery performed for the right indications from those of indiscriminate surgery inefficiently carried out.

The incidence of tonsillectomy varied in different areas of the world and in different social levels. In New York, of 1000 children who had been surveyed 61% had had their tonsils removed, and of the remainder all but 65 had been advised to undergo the operation. The more expensive the school, the greater was the chance that the pupils would be found to have had their tonsils excised. There were remarkably few reports on the correlation between bacteriological studies of the tonsil and the disease which tonsillectomy was intended to relieve. Comparisons were also lacking between the results of adequate therapy of such diseases as nephritis and cervical adenitis, and the results of tonsillectomy properly done and assisted by adequate therapy. Often tonsillectomy was worthless because the operation had been inefficiently done; the proportion of throats showing tonsillar remnants after operation ranged, according to different reports, from 42 to 77%. The tonsillar stump had a far higher bacterial content than the intact organ.

There was a great need for controls in assessing results. The peak incidence of tonsillectomy was in children aged 6–7 years. Yet it was at this very age that immunity against upper-respiratory infection was normally acquired. Many of the commonly accepted indications for the removal of tonsils and adenoids—such as frequent colds, growing pains, and cervical adenitis—were often signs of undiagnosed disease in other organs. For this reason, the results of eradicating the tonsils as sites of "focal sepsis" were disappointing. The reduced prevalence of tuberculous cervical adenitis was as likely to be the result of cleaner milk as of the increase in tonsillectomies. With accurate diagnosis and competent surgery, the results of tonsillectomy could be excellent; but these were swamped by the nu
unsatisfactory results of inaccurate and inefficient s

R. G. MACBETH outlined the history of the on, and indicated its rapid rise in popularity; as the year in which it was most often employed. a sensible hypothesis that the lymphoid tissue throat and nose acted as a defence mechanism, s machinery could be defeated and itself become e of infection. Overcrowding, defective hygiene home, and bad dietary were the common predis- causes of tonsillar infection. The surgeon's task decide whether a given pair of tonsils was harmful ficial. In this he got no help from the appearance of the tonsil. The parent, and above all the doctor, could give invaluable help in reaching a n. Welfare and school doctors were on the whole ble witnesses; they knew too little about the

s, he suggested, justifiable to remove the adenoids ave the tonsils when only the adenoids were to be diseased. The indications for adenoidectomy asal obstruction, snoring, purulent rhinorrhœa, quent attacks of otitis media, though commonly mptoms were the result of sinusitis. The tonsils be excised when: (1) there had been more than tacks of acute tonsillitis; (2) the patient had peritonsillar abscess; (3) persistently enlarged were present in the absence of nasal disease: tonsils were so large as to obstruct the faucial g; and (5) the jugulodigastric (tonsillar) lymph- were the site of tuberculous adenitis. There ed a mass of minor indications which it was t to describe in detail; the good family doctor provide invaluable help because of his prolonged ation of the debilitated and ailing child. Mr. h affirmed that the risk of a child developing poliomyelitis as a result of tonsillectomy must ghed against the benefit to be derived from the ion; tonsillectomy did not increase the liability omyelitis; but if poliomyelitis did occur it tended t the medullary centres if the patient had recently ubmitted to tonsillectomy.

real problem presented by "tonsils and adenoids" he disparity between the number of children ng operation and the number of beds available for For over two hundred years tonsillectomy had a beneficial operation if it was properly performed correct indications; and the number of children d for it was itself an advertisement of its tages.

R. SCOTT STEVENSON contended that the alleged nship between tonsillectomy and poliomyelitis was on transatlantic evidence which was so profuse self-contradictory that it could be made to prove verse, but Professor Illingworth, in reply, upheld w that the relationship was genuine.

. The general practitioner is in fact the principal t of social medicine in the field, and this is at once and the nightmare of general practice. There is al interest for the man who recognises that the real general practice lies in the promotion of health and prevention and cure of ill-health within the natural nment of family and community life. But there is nt frustration for the doctor whose training has moulded the view that the problems of disease must always be lered in isolation from the surroundings where they ed—for the surroundings will always intrude to thwart forts to recreate the artificial conditions of the hospital . . . In medical training it has sometimes been as h Mother Church, when sending a man to the mission in Darkest Africa, has trained him only in the finest of theology, while omitting altogether to discuss the le he would meet in his new parish, their beliefs and s, and their occasional primitive urge to eat missionaries." J. H. F. BROTHERSTON, *Universities Quart.*, August, p. 768.

Reviews of Books

Ankylosing Spondylitis

Part 1. F. HERNAMAN-JOHNSON, M.D., F.F.R., D.M.R.E., physician to the Charterhouse Rheumatism Clinic. Part 2. W. ALEXANDER LAW, O.B.E., M.D., F.R.C.S., assistant surgeon, orthopædic department. London Hospital. London: Butterworth. 1949. Pp. 200. 25*s*.

THE late Dr. Hernaman-Johnson practised first as a radiologist and later became physician to the Charterhouse Rheumatism Clinic. His ideas therefore lean towards radiology and radiotherapy, and his therapeutic approach is that associated with his clinic. He describes the spondylitic syndrome in detail, but offers no new ideas on the ætiology or pathology of ankylosing spondylitis. His chapter on diagnosis is good, and he emphasises the importance of adequate investigation of the young sufferer from backache. He differentiates ankylosing spondylitis from rheumatoid arthritis, but his chapter on differences between the two conditions is not very convincing, though the descriptions of the radiographic changes of spondylitis are good and are well illustrated. He describes treatment of the disease by radiotherapy, vaccines, chrysotherapy, bismuth, and thorium X, in that order, and adds a chapter on the general management of the patient. For the early stages of the disease he advocates wide-field X-ray therapy, though his technique has been almost entirely discarded by other workers. A brief chapter mentions the use of 'Cortisone' by Hench and his colleagues, and work on pregneninolone.

The second part of the book, by Mr. Law, is a well-illustrated and concise account of the surgical aspects of the condition. He discusses conservative surgical techniques, and gives a good description of spinal osteotomy and 'Vitallium'-mould arthroplasty.

Hearing and Deafness

A Guide for Laymen. Editor: HALLOWELL DAVIS, M.D., director of research. Central Institute for the Deaf, and research professor of otolaryngology, Washington University, St. Louis, Mo. London: Staples Press. 1949. Pp. 496. 21*s*.

THIS is a valuable guidebook for the person who has lost hearing in late life or is the parent of a congenitally deaf or hard-of-hearing child. The approach is both medical and psychological. No hearing-aid, Dr. Davis points out, can replace the loss of the ear's natural function; and it is only through training, and by adjusting his own emotional response, that a deafened person will find a hearing-aid of great benefit. Hard-of-hearing children should be fitted with individual hearing-aids as early as possible, because their speech development improves so much if they can hear enough to understand, or at least to keep their voices under good control. In the section on reablement Miss M. D. Pauls notes that lip-reading can be learnt by every deafened person, no matter what his age; indeed even people with normal hearing tend to lip-read unconsciously when their hearing is deadened by background noise. A hearing-aid never replaces the need to learn lip-reading, but it can help the learner with his lip-reading just as lip-reading helps with the use of the hearing-aid. The terrible frustration caused by loss of contact with the outside world can thus be overcome, or at least mitigated.

Most deaf-born children, says Dr. Raymond Carhart in his chapter on auditory training, have some residual hearing, as do those who, born normal, lose their hearing before they have learned to speak. He states emphatically that "if there is any suspicion that a baby is hard-of-hearing, his early years must be filled with loud and varied sounds," to stimulate whatever hearing he has. Hard-of-hearing children must learn what sounds are, and where they come from, and must be taught to understand the pattern of speech sounds. Then, even if they cannot hear all speech, they can at least learn to speak intelligibly and grow up to lead a normal life. He lays down rules for training based on the determination to "give the child full benefit of doubt." Dr. D. A. Ramsdell analyses the deep depression that sudden loss of the primitive function of hearing causes in adults—a depression that the deaf-born, for all their frustration, do not suffer, because they adjust themselves unconsciously to their condition.

Mrs. Tracy, in the foreword, puts the case of the deaf in a nutshell: "Granted that the first handicap of deafness lies in communication, it has often seemed to me that a close second might be the attitude of hearing people toward it and that the former would be considerably lessened if we could do something to improve the latter."

Gray's Anatomy, Descriptive and Applied

(30th ed.) Editors: T. B. JOHNSTON, O.B.E., M.D., professor emeritus of anatomy, University of London; J. WHILLIS, M.D., M.S., professor of anatomy, Guy's Hospital. London: Longmans Green. 1949. Pp. 1533. 84*s*.

THE new edition of "Gray" has a feature sufficiently rare among long-lived textbooks to excite comment: in spite of new material it contains fewer pages than its predecessor. This has been managed mainly by eliminating the section on surface anatomy and transferring its contents piecemeal to the appropriate places in the other sections. This is sound, since the surface anatomy of a given structure is nowadays more closely related to its topography, and no longer seems to the student an entirely separate subject—one which cannot be very important since it is tucked away at the end of the book. The type has been reset and many new figures replace worn-out plates; in some cases this process might have been carried further—for example, one figure of the diaphragm is indistinct and of little value. Two new X-ray photographs have been added, one of the lumbar vertebræ and one of a child's skull. In a book containing four films of the teeth and seven of the hand it is perhaps surprising that only one plain film of the chest should be included. The surface anatomy of the heart still conforms to the literally rigid inelastic pattern of the cadaver—with measurements in millimetres from the sternum. The beating heart is not yet an anatomical concept.

Lung Dust Lesions (Pneumoconiosis) versus Tuberculosis

LEWIS GREGORY COLE, M.D., F.A.C.R. New York: American Medical Films Inc. 1948. Pp. 478. $10.

THIS is a highly original publication by a physician who has held many radiological posts in his time, including that of professor of röntgenology at Cornell Medical College. It is not an orthodox textbook on the radiology of dust diseases and pulmonary tuberculosis, just as the author is not an orthodox radiologist. It is an attempt to apply a pathological yardstick to radiology by a pioneer who evidently enjoys the exploration of a difficult or a controversial subject, and who frankly confesses that if he has done nothing to change the accepted theories his hard work will have been wasted.

Dr. Cole graduated in 1898, five years after Röntgen discovered X rays, and has therefore seen the plant of chest radiology grow from its cotyledon stage upwards. One chapter of the book, indeed, is a reprint of an article published on the subject in 1910 in which he tells us he had made X-ray photographs of some hundred cases of early pulmonary tuberculosis as long ago as 1904–05. In due course this study led him to investigate silicosis and the pneumoconioses, and then to undertake the pathological check-up of their effects on which this book is based, and in which the petrological microscope and the study of the dust particles have played an important part. Fourteen years, he says, have been devoted to "simply recording what I have personally seen without reading the works of others"; and to summarise the results of such a very individualistic study is almost impossible. His attempt to study the dust particles within the framework of the fibrotic nodule which gradually surrounds them, with the aid of the petrological microscope, is a step in the right direction—we have made too little use of this instrument. He stresses the difference between the collagen of pneumoconiosis which tends steadily to increase, and reparative connective tissue formed elsewhere which contracts with age. He sees in this a difference in kind rather than of degree and would not include the collagen of the pneumoconioses among the connective tissues. His radiological-pathological classification is original, with a new terminology of vesicular, tuberculoid, cystic, and
usually accepted nodular, perivascular, and
varieties.

Altogether Dr. Cole intended to write—and
written—a most provocative book.

Green's Manual of Pathology (17th ed. Lon
Baillière, Tindall, and Cox. 1949. Pp. 1200. 4
Thanks to vigorous reducing the latest edition of this
book is only 34 pages longer than its predecessor—
an achievement in these days of expanding specialties.
H. W. C. Vines speaks in his preface of "a faint
spreading over the days of descriptive pathology," the
partly of chemotherapy, and partly of a changing
in medicine—from the study of end-pictures toward
study of the beginnings of disease. These factors
time change textbooks; but, as he says, the old orde
holds sway; and this book sets out well the princip

THE PLACE OF *Pertussis Vaccine* IN ROUTINE PROPHYLAXIS

Investigations in the Glaxo Laboratories have established criteria for the selection of strains of organisms and for methods of growth which result in a pertussis vaccine giving highest immunological response . . .

A vaccine prepared in accordance with these standards is incorporated in Diphtheria-Pertussis Prophylactic *Glaxo*—a preparation affording the convenience of combining pertussis immunisation with routine diphtheria preventive measures. Three injections are advised for primary immunisation—0.5 cc., 0.5 cc. and 1 cc. at 4-weekly intervals. For pertussis immunisation alone, Whooping Cough Alum-Precipitated Vaccine *Glaxo* is now widely employed, containing 20,000 million H. pertussis in each cc.

B.D.H. SEX HORMONES

Tablets for oral or sublingual administration

ETHISTERONE B.D.H.
The orally active derivative of progesterone. Indicated in habitual abortion, to supplement parenteral progesterone in threatened abortion, to control excessive or irregular uterine hæmorrhage and to give relief in certain cases of dysmenorrhœa.

METHYL-TESTOSTERONE B.D.H. The orally active derivative of the testicular hormone. For the treatment of endocrine impotence and male climacteric. In the female, indicated for menorrhagia, premenstrual tension and mastodynia, especially those cases which do not respond satisfactorily to progestational substances.

ETHINYL ŒSTRADIOL B.D.H. 'ESTIGYN' The orally active derivative of the natural hormone, œstradiol. Indicated particularly for the treatment of menopausal disorders, inhibition of lactation and prostatic carcinoma.

Literature on these products is available on request.

ıfection in the Operating-theatre

NUS following surgical operations is rare in
practice, though among the 3000-odd cases
ıus collected by WAINWRIGHT[1] some 10%
stoperative. The source of infection in these
rative cases is usually difficult to prove.
has been most often incriminated, but
tly sterilised dressings, talc and sulphon-
owders, and the patient's skin and intestinal
ve all been suspected. The risk to parturient
from unsterile sanitary pads was emphasised
VERTAFT,[2] and some years ago there was a
eries of 5 fatal cases of tetanus ascribed to
of cervical packs to induce abortion.[3]

ıatural habitat of the tetanus bacillus is the
e; domestic animals (horse, cow, sheep, dog,
d rats have been shown to be carriers in varying
ion, but in this country the organism has
een found in human excreta. Tetanus spores
efore to be found in manured soil, street dust,
e like, which is why prophylactic tetanus
n is given routinely to accident cases. The
inated dust may be carried into a hospital
n into the operating-theatre by soiled shoes
ments; or it may be aspirated into the theatre
e outside air by natural ventilation. Moreover,
l ventilation is often so designed that it sucks
o the theatre from the surrounding wards and
s. Three years ago ROBINSON, McLEOD,
WNIE[4] described 2 cases of postoperative
in which there were good grounds for believ-
t the source of infection was contaminated
Bacteriological examination revealed toxi-
lostridium tetani in the dust of the operating-
in both hospitals, while soil in a field
ls from the windows of one of the theatres
und to be heavily contaminated. In an
ation of dust from 11 operating-theatres in
land hospitals, they found tetanus bacilli—
easy organism to isolate and identify—in
instance and that was from a theatre adjacent
f the two which had already yielded positive
The organism was found in the ground adjacent
of three hospitals where search was made.
issue (p. 1075) Dr. SEVITT describes another,
her unexpected, source of *Cl. tetani* and other
nic sporing organisms in a hospital operating-
—goat hair, which was being vigorously
before being incorporated in plaster by the
pairing a second operating-theatre nearby.
haust ventilating system probably helped to
nate the contaminated dust throughout the
suite, and the talc glove powder, regarded as the most likely vehicle for introducing tetanus spores into the wounds, was also apparently infected from the blown dust.

Surgical wounds are contaminated in the theatre probably more often than the surgeon believes, but such contamination is ordinarily not significant because the organisms are non-pathogenic, or, in small numbers, are readily destroyed by the tissues. However, serious complications may result from such contamination, as COWAN[5] has shown in neurosurgery; and DARYL HART[6] reported a high incidence of infected scars in chest surgery before he introduced an ultraviolet light barrier. With large raw-areas like burns the risk of airborne infection during the surgical toilet is much greater, and because of this BOURDILLON and COLEBROOK[7] devised a special dressing unit with an air lock and a forced ventilation plant which delivered filtered, warmed, and humified air from the ceiling so as to change the air 10–20 times per hour without discomfort to staff or patient. Such a plant is expensive to install and maintain, but is fully justified where large open wounds have to be dressed and perhaps in theatres intended for cranial and chest surgery. In many existing general surgical theatres the ventilation arrangements are highly unsatisfactory, and wherever possible a plenum system with an intake of filtered air at roof level should be installed in place of the exhaust type of ventilation which is calculated to draw dirty air and dust *into* the theatre. Hospital authorities who insist on clean milk and clean water should be equally particular about the cleanliness of the air in their operating-theatres and casualty dressing-rooms.

Milk

IN the production and distribution of the nation's milk, three important developments are discernible: first, administrative responsibility is being spread among a growing number of bodies, headed by the Ministries of Agriculture, Food, and Health; secondly, bovine tuberculosis is on the wane and a scheme for "area eradication" of tuberculosis is to be started next autumn; and thirdly, milk is to be made safer by gradually extending the areas in which pasteurisation is to become compulsory under the Milk (Special Designations) Act, 1949.

The administrative machinery has been reviewed by a joint committee of the British Medical Association and the National Veterinary Medical Association, whose report on the Provision of Safe Milk of High Quality appears this week. Besides the three Ministries—each with its inspectorate, local organisations, and area officers—the bodies concerned are the Milk Marketing Board, the county agricultural executive committees, the food and drugs authorities, the county and county-borough councils, and the local sanitary authorities. With the addition of tribunals, central and county advisory committees, and joint committees of producers and distributors, the number of organisations is likely to become still greater; and the committee asks itself whether this massive structure will be either economical or conducive to coördination. In particular, the diffusion among

the three Ministries of the responsibility for making regulations may "create a defensive system in Parliament which might well prove impenetrable." Broadly, the Minister of Agriculture now becomes responsible for all production problems, while the Minister of Food takes over many of the former functions of the Minister of Health; and the committee maintains that larger duties should be allotted to the Minister of Health and those answerable to him:

> "The authority responsible for the health of the community [should] be authorised and required to take regularly at the farm samples for biological tests. . . . Sampling and testing are skilled jobs and their efficient organisation may have a profound effect upon public health. The Committee takes the view that the whole of this work should be united and suggests that it should be allocated to local authorities at County and County Borough levels, operating through their medical Officers of Health actively coördinated by the Minister of Health."

In the second development—the reduction of bovine tuberculosis—this country lags far behind some others which have wholly eliminated the disease from their dairy herds. However, the position is improving, notably through the attested-herd scheme which was introduced in 1935.

> "In Great Britain, where in 1931 it was estimated that 40% of cows would react to tuberculin, and that 0·2% were affected with udder tuberculosis, the incidence has been greatly reduced. In 1945, it was calculated that from 30 to 35% of cows and 17 to 18% of cattle would react (England 20%, Wales 7·5%, Scotland 14%): at that time there were approximately 890,000 cattle in the tubercle-free herds . . . there are now some 1,704,000 cattle in such herds."[1]

Attested herds will be the basis for the scheme of area eradication of tuberculosis which the Minister of Agriculture[2] has undertaken to start next October. But eradication by this scheme will be a slow business; and the joint committee, while acknowledging that wholesale slaughter of tuberculin reactors is not feasible, urges that the test should be more widely used for survey purposes, and suggests that possibly reactors might be branded. Immediate eradication has been ruled out because the slaughter would cause a disastrous fall in the milk-supply and serious disturbance of farm economy: the cow plays an important part in maintaining soil fertility, and moreover a proportion of replacement stock must be bred from the tuberculin-positive. Yet ultimate eradication of tuberculosis will benefit the farmer hardly less than the milk-consumer. By one estimate,[3] the milking life of a cow in a tuberculous herd may be some three years, compared with five years for a cow in a non-tuberculous herd. If the milking life is longer, more heifers are available for replacement, making it possible either to produce more beef, increase the size of the herd, or, by selective breeding, develop a herd with greater milk-production.

Perhaps the best that can be hoped is that the area eradication scheme will have been completed within the next two decades. Meanwhile, the only raw milk which can be reasonably assumed to be consistently free from tubercle bacilli is that designated "tuberculin-tested."

> From Oct. 1, 1957, this designation is to be used for milk from an attested herd. The latest regul also recognise the special designation "acc though this is to be abolished on Oct. 1, 1954. supplied under this designation must conform to same bacterial requirements as does T.T. milk, but *designation does not imply routine tuberculin-testing* herd; and the joint committee holds that the desi should be abolished forthwith.
>
> The four designations[5] approved for milk that been heated are: "pasteurised," "sterilised," " culin-tested (pasteurised)" and "tuberculin- (sterilised)"; from Oct. 1, 1950, pasteurised milk be sold only in bottles or other containers, and Oct. 1, 1954, the bottles or other containers mu *filled at the pasteurising premises.* Milk tha "sterilised" becomes partly caramelised; and *committee urges that after this designation shoul* added "unsuitable for babies," and that the desi should be discarded as soon as possible.

Even now about 70% of milk sold for consum as a liquid has been given some form of heat t ment; but, mainly because of lack of machi it may be 5–10 years before all milk is pasteur Until that time comes a proportion of the p will run an avoidable risk of contracting, thr milk, not only the diseases of cattle but also diseases of those who care for them.

The Blood-vessels in Tuberculous Meningitis

THE clinician dealing with tuberculous menin today needs a sound knowledge of its underl pathology if he is to understand the prob presented by the disease before, during, and treatment. In this form of meningitis, as in acute purulent varieties, there is a tendency to t mainly in terms of the inflammatory involveme the pia-arachnoid and to forget that other structures are often implicated. TROUSSEAU[6] so impressed by the focal signs in life and the cere softening at autopsy that he suggested substitu the name "cerebro-meningitis" for "meningitis tuberculous cases. Localising signs in the ner system are common, with or without specific tr ment, and in the past they have too often b ascribed to hypothetical tuberculomas. At necro these have been hard to find, but in their place a of softening of the grey or white matter of on both cerebral hemispheres may be seen. We know that the softened areas are in fact inf produced by an occlusive arteritis of the basal ve of the brain as they course through the subarach exudate.

That the blood-vessels of the brain (both arte and veins) are involved in tuberculous meningitis long been recognised. The first account of the vasc lesions was given by BAUMGARTEN[7] in the latter of last century. He compared the changes in meningeal vessels in tuberculosis with the similar c occurring in the smaller arteries in syphilis. The n notable contribution, also in German, was ASKANAZY,[8] who described and classified the hi logical appearances in the vascular tunics of

s in tuberculous meningitis and commented e first time on the fibrinoid swelling of the ., a finding stressed by most subsequent writers. e time it was believed that the arteries were ed from within by the hæmatogenous spread of le bacilli,[9] but later histological evidence d convincingly that they were affected from tside in their passage through adjacent meningeal te.[10] More recently, Winkelman and Moore [11] merica gave an excellent description of the e pathological changes in the basal vessels of rain, and in this country Smith and Daniel,[12] pating the introduction of streptomycin and chemotherapeutic agents against tuberculosis, with the clinical and pathological aspects of l nervous system involvement. Smith and el emphasised the destructive changes in the geal and smaller penetrating vessels of the , which they felt were a sufficient basis for ftening commonly found. They rightly pointed hat if the treatment of tuberculous meningitis achieve recovery and not mere survival it must tarted before these vascular changes produce mic lesions and their accompanying crippling s. Their timely warning must be taken to if permanent sequelæ are to be avoided. latest study is that of Doniach,[13] who confirms ndings in the meningeal vessels in acute untreated rculous meningitis and contrasts the histological ges with those found in unsuccessfully treated ren under the age of 7 years who had survived eriods ranging from a few weeks to just over one Some of his cases had relapsed after completing urse of streptomycin. Scarring of the basal els with reduction or obliteration of their lumen the most striking change in cases which had surd for ten weeks or more. In treated cases dying in a month of onset the picture was essentially lar to that in the untreated controls. There was ing to suggest that the streptomycin introduced thecally was responsible for the vascular effects; could all be explained in terms of the prolongation fe. Indeed, similar changes have been recorded re in untreated cases where life had been prolonged ral weeks after the appearance of meningeal s.[11] In both the untreated and treated groups medial coat of an involved vessel seemed to play urely passive rôle, and, though sometimes harting a few migrating cells, usually preserved a nal appearance between the affected intima and entitia. Occasionally, all three coats and the en were involved in a caseous necrosis which ed part of a more extensive meningeal lesion. he relapse group scarred vessels imbedded in old ous exudate were associated with acutely inflamed els caught in fresh exudate.

xperience with the treatment of tuberculous ingitis has shown that cases presenting with focal s in the nervous system usually carry a bad gnosis, and that the relapse-rate in patients who ond to an initial course of treatment is high when there are residual neurological signs. The pathology of untreated and treated cases provides a rational basis for this clinical observation and also underlines the need for early diagnosis and early treatment. Our aim must be to give streptomycin before exudate and adhesions have formed in the subarachnoid space, and if we accept the work of Macgregor and Green [14] this is a comparatively late event. Once this basal exudate becomes extensive the normal flow of cerebrospinal fluid to the absorbing area at the vertex may be obstructed, causing hydrocephaly; the free circulation of streptomycin introduced into the subarachnoid pathways from below may be impeded, so that its access to all the sites of infection becomes difficult or impossible; various cranial nerves in relation to the base of the brain may be constricted and damaged, leading to blindness and permanent nerve palsies; and lastly, as we have seen, irreversible changes may be induced in the basal meningeal vessels coursing through the tuberculous exudate.

Annotations

WATER ! WATER !

The warning given last month by a working party of experienced water engineers [15] has received too little attention. They tell us that supply cannot meet demand. The population increases; agriculture and industry, working at high pressure, need quantities of water; housing schemes are pressed forward as fast as present conditions permit; new towns are springing up; greater domestic comfort and convenience are expected; villages cry out for piped supplies; indoor sanitation and proper sewerage must follow; progressive municipalities nowadays ask Parliament for powers to furnish hot water to householders—indeed, in the last few days the early stages of next year's local legislation have revealed that seven more local authorities are petitioning for this fashionable form of civic enterprise. All these phenomena may be matter for admiring congratulation, but they all demand more and more water. The water is not there.

In the ten years from 1938 consumption has gone up by 20% in England and Wales and by 10% in Scotland. Statistics indicate that, if the rate of increase continues, water undertakings will be faced in 1970 with a demand for twice the amount consumed in 1938. Water undertakers are several years behindhand in the normal expansion of their works. The war prevented capital expansion and deferred the tasks of maintenance; post-war shortages of labour and materials obstruct the making good of arrears. Water-supply is linked with sewage disposal. " Here again," say the engineers, " the foreseeable demands far exceed potential resources." They anticipate increasing competition from the new hospital and health services, and from local government needs, for the labour and materials allocated to the health departments of England and Scotland; and all these requirements " must be related to those of coal, gas, oil, transport, power and the export trades." Things may right themselves in time, but meanwhile there is something like a crisis in the short-term prospect.

Can anything be done? Well, at least, say the engineers, we can try to eliminate waste. Mr. G. M. McNaughton, chief engineer to the Ministry of Health, stated recently that, if a figure of eight gallons per head were taken as the daily waste, it represented approxi-

[15] Interim report of the Comittee on Causes of Increase in Consumption of Water: Ministry of Health.

mately the whole supply to London or the supply to six towns the size of Manchester. The engineers' report devotes several pages to technical methods of detecting and preventing waste. As most of our urban systems are about a century old, plant must be looked to. Extremes of weather, traffic vibration, soil subsidence, air-raid concussion, and the use of the "booster" will have damaged mains and service pipes. In one recent instance a serious drop in the level of a reservoir was traced to a leak from which over 40,000 gallons had been escaping daily for a long period into an underground cavity. Undertakings are advised to review their system of inspection—is closer supervision wanted, is existing man-power properly used, ought more inspectors to be appointed, is their training adequate, are records of supply and consumption (including night flow) kept, can waste-water metering be adopted or extended, are all physical measures against corrosion, faulty fittings, and bad workmanship being applied, can water supplied for industrial use be recirculated? Above all, can consumers be induced to coöperate? Can they be made to realise that, before the finished product reaches the tap, expensive steps have to be taken to collect it, store it, treat it, and distribute it? The cottager who carries his supply in a bucket from a well is naturally more thrifty than the folk who have been brought up in a complacent world where a tap is turned on and water gushes forth abundantly. Some better propaganda is wanted than the mere repetition of injunctions not to waste water. During the next few years there will be a formidable menace to our improving standards of public health and personal hygiene. What are we doing about it?

THE CHRONIC WARDS REVIEWED

STUDIES of the aged sick in hospital are multiplying as our understanding of what can be done for these old people grows. Last week we published a review, by Dr. J. M. Greenwood, of 399 patients in the chronic wards of a general hospital in Manchester; and this week Dr. G. F. Adams gives an account of 310 patients treated in the chronic wards of the Belfast City Hospital between August, 1948, and July, 1949. A report on 701 patients in Bradford hospitals, by Mr. Peter McEwan and Dr. S. G. Laverty, has also appeared, and we reprint some of their conclusions. All three studies serve to drive home once more the lesson that a very large proportion of cases formerly thought to be hopeless can be expected to respond well to treatment. At Manchester 205 out of the 399 were adjudged likely to benefit. At Belfast 58 of the 310 patients were classed as "elderly infirm," 67 as remediable sick, 107 as irremediable sick, and 78 as psychiatric cases; but at the end of a year 14 who had been classed as irremediable and bedfast had advanced to the ranks of the elderly infirm—i.e., they were up, dressed, and walking for the best part of the day—and 10 more "irremediables" had benefited enough to go home or to be transferred to resident homes. Against this must be set the fact that 15 who were expected to respond to treatment had not done so. In all, however, 76 patients had responded. The Bradford survey is not concerned with treatment, but is a careful estimate of the physical state of the patients—"the final result of the hospital system of the past, which is now, it is to be hoped, nearly at an end." Even for these old people, decrepit in body and mind, much can be done; but the chief aim of the geriatric service, in McEwan and Laverty's opinion, must be to keep other old people from falling into a like state.

All the writers agree that this can only be done if enough resident homes are provided into which the hospitals can transfer reabled old people who are homeless, or whose homes are unsuitable for their return. Such homes will free hospital beds for those who need active treatment; and the old atmosphere of stagnation in chronic wards can be exchanged—as p have shown already—for a spirit of liveliness and Dr. Adams reminds us of Mr. L. Z. Cosin's f that among patients over sixty admitted to c wards, 40% may be expected to die within a year, 40% can be made fit enough to be discharged, and 20% will need continued care in a long-stay a By treating such old people actively Dr. Marjory W has been able to empty beds long filled, and to subs 200 beds with a turnover for 700 beds with stagnati

RETICULOCYTES AND LIVER ACTIVITY

WHEN a potent liver preparation is given by any to a patient with pernicious anæmia in relapse first striking change to be seen in the peripheral is an increase in reticulocytes; the proportion of ret cytes rises steadily for a few days to a peak and falls, though to a still elevated level. The ri fall takes about a fortnight, at the end of whic red-cell count and hæmoglobin level are found to be and this rise is sustained if further treatment is The "reticulocyte peak" was one of the earliest ob tions made when liver treatment for pernicious a was introduced, and it was noted that the pea centage of reticulocytes reached was roughly in proportional to the initial red-cell count—i.e., the the red-cell count before treatment the highe reticulocyte peak produced by a given dose of a liver preparation. It is not surprising therefor many attempts have been made to devise fo from which the height of the reticulocyte peak or t in red cells and hæmoglobin could be predicted fr initial red-cell and hæmoglobin levels. With a formula of this kind the actual results produced batch of liver extract could be compared with the ex results and the comparison used as an estimate potency of the batch.

This game of formula-devising has now gone some twenty years with indifferent success. No f has been generally accepted or has recommende to interested official bodies in this country. destructive criticism has been levelled at them, our last issue Dr. Kohári-Kuchárik quoted some disadvantages and proposed another remedy. Clark[1] collected a vast amount of information fr records of 228 pernicious-anæmia patients in the He found that less than half of the reticulocyte obtained reached the standards calculated ac to those used by the U.S. Pharmacopœia anti- preparations advisory board. And closer invest revealed three serious difficulties: (1) that the s of liver extract given to patients with very simila red-cell counts could produce widely differing r cyte peaks; (2) that there could be a good retic peak and yet a poor subsequent rise in red ce hæmoglobin; and (3) that there could be als reticulocytosis and yet the red cells and hæmo rose at maximum rate. Della Vida[2] sought to come these difficulties by eliminating the reticu count altogether from the calculations and his assay on the initial red-cell count and the rise in red cells during the first fortnight after ment; but his formula too does not overco disadvantages inherent in such methods.

These findings will surprise few workers wh had long experience in observing the effect o extracts on pernicious anæmia. In fact, ind variation of response can cause so much confusi the surprising thing is not that these formu criticised but that their results were ever co enough for them to be seriously considered. animal test, the variations could perhaps be mi

2. Della Vida, B. L. *Lancet*, 1942, ii, 275.

ng a large population and applying statistical ls; but the assessor of liver-extract potency y if he can find five suitable patients on whom to particular batch. So most assessors base their n on all the evidence they can get—the reticulo- eak; the subsequent rise in red cells and hæmo- and whether this rise can be maintained and ied up to normal figures; and the patient's l improvement. In this way a reliable *qualitative* n can be given on the activity of a particular xtract. *Quantitative assessment is another matter;* venty years of failure suggests that some yardstick than clinical response must be found before there a generally acceptable standard.

ASSESSMENT OF PHYSICAL FITNESS

small group of investigators studying the practical s of physical fitness in this country has expanded last few years, largely as a result of the war and idening interest in the workings of the intact n being. Along with this expansion there has been eral recrudescence of applied physiology. For the ime since 1930 the Medical Research Council has of applied physiology, about to begin work under lm; the R.A.F. Institute of Aviation Medicine n to be enlarged; and a year ago the *Journal of ed Physiology*—at present mainly American, but ied to meet an international need—began cation.

ysical fitness is an awkward thing to estimate. the assessment of nutrition, some sort of criterion plied, and criteria of normality, though familiar to linician and social scientist, are somewhat foreign e physiologist. Then, though it is certainly possible excessively nourished, can one be excessively fit? there is always the question with which the artist *unch* retorted when asked how he kept fit: "Fit hat?" The technical methods used in assessing s are simpler than those of classical animal experi- ation, but the interpretation of results is incom- bly more difficult. The investigator must be thing of a jack-of-all-trades—physiologist in tech- e, clinician in approach, and sportsman in sympathy. kes a brave man to survey, even with simple tests, physical fitness of an entire Dominion, but this is Professor Cullumbine has done in Ceylon, with ts reported in the opening article of this issue. tests used were comparatively recent versions of ld procedure. The subject stepped on and off a bench imes a minute for five minutes in the "moderate cise" test, 45 times a minute for as long as possible ae "endurance" test, and 30 times a minute for as as possible in the "exhaustion" test. The effects blood-pressure and heart-rate were used as fitness es. There were also speed and strength tests. A lot ork has already been done with these and similar s, and Cullumbine's admirable large-scale survey not contradict the more laboratory-sized results. known, for example, that the amount which the t-rate rises on standard exercise and the promptness which it returns to the resting level are related to sical training, psychological state, and physique. emost in demonstrating the effect of a physical- ning programme was Craig Taylor in the U.S.A., in the study of the psychological state Maxwell es[1] and his associates in this country. In neurosis en the mild neurosis that overtakes us all from time ime, and not only the more spectacular effort syn- me—physical fitness declines. Women, on average, less well than men in these tests, and men tending ards the female in body build do less well than larly trained men of more exclusively masculine earance. The physiological reasons for these differences seem to be complex and may not be the same for training as for psychological state and physiqué. Neurosis may act by affecting the sympathetic control of the muscular blood-vessels,[2] but there are many other possible mechanisms. We are almost completely in the dark here. Why, for example, do muscles hypertrophy on constant use, and why do they do so only to a limited extent? Are there actual changes in enzyme concentrations in the muscle cells, so that less lactic acid is produced on exercise in the trained subject? Is there a hormonal explanation of the sex differences in physique, for it is said that hormones can alter cell-enzyme concentrations? There is enough in the intricacies of the subject to keep both surveyor and laboratory worker happy for many years to come.

SOMATIC EXPRESSIONS OF PSYCHIC EVENTS

THE body has a very limited repertoire of responses to stimuli. The skin can sweat with fear, embarrassment, or enthusiasm; the pupils can dilate, the mouth go dry, the heart beat fast, and the intestines rumble with wind, either through terror or pleasurable excitement. Rage, happiness, or grief may bring tears to the eyes. Or again a single emotion may be offered a limited choice of responses: anxiety may tighten the sphincters or relax them, fear may tauten the muscles or leave them as limp as wet paper. It is the same with most organs: plain muscle can only contract or relax; glands and mucous membrane can secrete, vary the quality of their secretion, or go dry; voluntary muscle can become tense or flaccid; and these responses all express changes in the vegetative nervous system—the sympathetic or the parasympathetic as the case may be. Even when the stimulus takes the form of a disease the body has only a limited number of things it can do about it.

Considering what a small box of conjuring-tricks we have at our disposal, the general effects we produce are wonderfully varied. Dr. Harry Stalker, considering the psychosomatic diseases,[3] points out that even the simplest disease is the result of multiple or cumulative stresses which break down the powers of adaptation or compensation. Some of these will affect the tissues, some the patient's way of looking at things; and the changes in mind and body will have reciprocal effects on body and mind. Looked at in this way every disease is psychosomatic; but it is convenient, as he says, to have a defined concept of what we mean when we talk about the psychosomatic diseases; and he recalls the classification of Weiss and English[4]: group I, sick people who are not "out of their minds" and yet have no definite bodily disease to account for their symptoms (the so-called functional disorders); group II, patients whose symptoms depend partly on emotional factors, even though organic disease—possibly serious—is present; and group III, disorders generally held to be wholly within the realm of "physical disease" and which have to do with the vegetative nervous system. Stalker suggests that the term "psychosomatic diseases" should be reserved for those in the third group, and offers the following tentative list of them:

> The paroxysmal rhinorrhœas, bronchial asthma, gastric and duodenal ulcer, ulcerative colitis, essential hypertension, arterial degeneration (including coronary-artery disease arising before *the senile age-period), hyperthyroidism, migraine,* chronic arthritis, some skin diseases, enuresis, and primary dysmenorrhœa.

The bodily manifestations in these diseases, he suggests, correspond to the bodily changes associated with the aggressive emotions—raised blood-pressure, increased

respiration and voluntary-muscle tone, tense posture and expression, gastric hypersecretion, intestinal hypermotility, and perhaps diarrhœa. They are, in fact, manifestations of an active sympathetic system; and he contrasts them with the signs of parasympathetic activity—the low blood-pressure, relaxed muscles, and sunken eyes—found in depression and neurasthenia. He is careful to remind us that these too are positive responses, and not merely the result of reduced sympathetic activity: the parasympathetic system is as capable of overaction as the sympathetic. The bodily effects of fear and anxiety lie somewhere between the two groups and are seen in anxiety neurosis. If his classification is correct, or roughly correct (for he confesses it is too neat for nature), then those with psychosomatic disorders should present evidence of aggression, latent or manifest. And sure enough, it seems that in the case-histories of such diseases "anxiety, obsessionalism, and more or less latent aggression are almost constant findings."

What decides the choice of symptom? Stalker suggests a hereditary predisposition to react to stress in a specific way; but this is only to say: "The boy is asthmatic because that's the kind of boy he is." Stalker, however, is merely presenting a hypothesis about the uncharted land of psychosomatic diseases: he admits that "nearly all the laborious, careful, and detailed work of exploration has still to be done."

THE HEALTH OF WELSH STUDENTS

THE attitude of students to their university career varies considerably. A survey by Dr. R. A. N. Hitchens and Dr. Graham Grant[1] shows that a high proportion of students in the University of Wales are thought to make inadequate use of their leisure, whether in the playing-fields or in cultural pursuits. The aim of many of them is to get through their course as quickly as possible and begin to earn, so that they may cease to be a burden on their families, who are often poor. Others find sports too expensive, or have to spend too much time in travelling, or are too much afraid of failing in their examinations (and thus losing their ex-Service grants, or being called up) to spare time for recreation. Not all the constituent colleges have good facilities for sport; and some of the students are apathetic about leisure activities. "The idea seems to be widespread that single-minded attention to studies and the avoidance of leisure activities is the most efficient way of pursuing a university career." This implies a sad, and possibly narrowing, misuse of opportunity, and almost certainly has an unfavourable effect on health. The survey is the first of a series of annual reports to be made on Welsh students, and is based on the study of 1002, mostly newly entered, who agreed to be examined; they represent some 64% of the whole entry.

Any deviation from the normal (however slight) which might have an adverse effect (however slight) on the student's health was noted as a defect; and on this criterion defects averaged over 2 a head. Psychological disturbances were found to be few and mild. Among the student population of all years the incidence of tuberculosis —as gauged by mass radiography—was low (0·7%); but only 3240 out of 5095 agreed to be examined, the proportions ranging from 49% in the University College of Wales, Aberystwyth, to nearly 80% in the University College of South Wales and Monmouthshire and the College of the Domestic Arts, Cardiff. At two of the colleges the students were Mantoux-tested, and next year this is to be done in the other colleges as well. Dr. Hitchens and Dr. Grant suggest that recreational opportunities might be improved, and they hope to develop health education through small group discussions.

ERIATRICS IN NORTHERN IRELAND *

G. F. ADAMS
M.D. Belf., M.R.C.P.

background to the urgent problem of the aged sick h the same in Northern Ireland as in England. oor Law Act of 1834 enabled the boards of ans to found 27 workhouses in Northern Ireland. were already 6 county infirmaries but few other itions for the treatment of the sick ; and, though orkhouses were originally intended for able-bodied nte persons only, it became necessary to provide imodation for the sick poor also.

Local Government Act of 1898 empowered the ians to convert union infirmaries into district tals under the control of independent governors. 946, 13 had been converted ; 4 were closed com- y (able-bodied and infirmary wards) and 17 were l to able-bodied persons. Thus the workhouse for odied destitute people was separated again from sociation with the infirmary for the treatment of ck, and more hospitals were provided at the expense iat we might now call welfare cases. This transition ved a natural downward trend of admissions to the house as social conditions improved in the past years. But the downward trend was more apparent real, for, though there was a fall in admissions to vards for feeble and infirm in the workhouse, there a steady rise in admissions to the general wards of nfirmary. and it is important to note that admission l not be refused. Therefore, in addition to a constant w of new patients, especially in winter, the voluntary itals sent a steady stream of " chronic " cases from wards to the infirmary.

July 5, 1948, the Northern Ireland Hospitals ority was bequeathed a legacy of these hospitals in various stages of repair, transition, and disrepair ; despite the renovations and alterations following the Act, the hospitals are mostly too small for an easingly " hospital-minded " population and lacking any modern hospital facilities. The old regulation reby admission could not be refused has gone, for hospital wants to reduce beds in overcrowded ds and to be able to say it is full when it *is* full. This good thing in some ways—it will induce hospitals ry to solve the problem of their own long-term sick eliminating convenient institutions into which a ient, considered to be irremediable, may be dumped, ether with any further medical or social responsibili-, and the burden of finding a solution to this problem l be distributed and shared by many persons rather n by an unfortunate few who will " grow stale and lose rt if overwhelmed by a preponderance of long-term ile patients with incurable diseases." [1] But the version and renovation of the union infirmaries has oubtedly created a crisis in the lives of many of the nic sick, the elderly infirm, and their family doctors.

The development of interest in the medical care of the derly in Northern Ireland has followed the pioneer ork in England, and in 1946 some ex-Service registrars ied to sort out a large group of so-called chronic sick atients in one hospital. At that time they had no uthority to take any active steps to improve the situa- ion, and, on the whole, the doctors gained more from he interesting clinical work than did the astonishing nixture of patients they found. Since July last year the Hospitals Authority has become interested in geriatrics because they badly need more beds, and examples such as Dr. Marjory Warren's convincing substitution of 200 beds with a turnover for 700 beds with stagnation enables them to see a means of obtaining some of them.

BELFAST CITY HOSPITAL

In the summer of 1948 a start was made in the Belfast City Hospital. This was at one time the largest Poor-Law union infirmary in the United Kingdom, and it has been partly converted into a general hospital with 1800 beds, of which 500–600 are set aside for the chronic sick. In a remote and antiquated three-story brick building, euphemistically named the " convalescent buildings," are 350 of these beds, in six large wards, three in each of the well-separated wings of the block, and between these wings communication is possible only on the ground floor. There was a heterogeneous collection of 60 beds and cots in each ward, of which one corner is partitioned off as a ward kitchen with an old-fashioned range and a battered sink. There are no lifts, the stairs are narrow, the lighting is poor, and the windows contain many panes. Patients were kept in bed to avoid falls because staff was minimal (at times only one nurse and an orderly were available), and apathy was paramount. There are some redeeming features: the wards are wide, good annexes were added in the 1930's, there is central heating (but the plant was not working efficiently), and the top-floor wards had been repainted after the war. The few nurses deserve the greatest credit for the way in which they managed to look after their patients under the difficult conditions. Not only did they succeed in keeping them, with few exceptions, free from bedsores and clean (despite scarcity of bed linen and clothing), but the wards themselves were remarkably well kept though, in such an old building, dust and dirt accumulate rapidly unless constantly swept away.

A rapid survey was made of the building and its inhabitants, and a report based on the recommendations of the British Medical Association was made. Additional staff, including an almoner, a physiotherapist, and an occupational therapist, were asked for, and reconstruction and renovation of the whole block recommended as the only alternative to pulling it down and rebuilding. However, Lord Beveridge's dictum has been taken to heart: " It is dangerous to be in any way lavish to old age until adequate provision has been assured for all other vital needs, such as prevention of disease and the adequate nutrition of the young." Geriatrics is such a newcomer that maternity services, pædiatrics, tuberculosis, &c., already have well-established priority. The programme which, it was hoped, would be completed by the end of the first year still hangs fire, but we did achieve something. Dr. Warren kindly arranged to take two sisters and two staff nurses for a short course of training in her geriatric unit. This training experiment has stimulated great interest and, by giving the nurses an ideal to aim at, enables them to carry on despite the depressing conditions under which they must continue to work for an indefinite period. We are most fortunate in our almoner, Miss E. M. Sargaison, who has a genuine interest in geriatric social work and has made the arrangements for most of the discharged patients, enabling the number of beds in the overcrowded wards to be reduced and a turnover, however small, to be maintained.

The segregation and redistribution of the 310 patients was a time-consuming task, and a temporary arrangement was made whereby only transfers from the general wards were taken and no new patients were admitted. Results last winter justified this step, for we were able to substitute some sort of order for the chaos in our wards and at the same time prevent the general wards from silting up during the winter with elderly long-term sick. Irremediable patients from the younger age-groups were not admitted, because the responsibility for their rehabilitation and social welfare should rest with the general respiration and voluntary-muscle tone, tense posture and expression, gastric hypersecretion, intestinal hypermotility, and perhaps diarrhœa. They are, in fact, manifestations of an active sympathetic system; and he contrasts them with the signs of parasympathetic activity—the low blood-pressure, relaxed muscles, and sunken eyes—found in depression and neurasthenia. He is careful to remind us that these too are positive responses, and not merely the result of reduced sympathetic activity: the parasympathetic system is as capable of overaction as the sympathetic. The bodily effects of fear and anxiety lie somewhere between the two groups and are seen in anxiety neurosis. If his classification is correct, or roughly correct (for he confesses it is too neat for nature), then those with psychosomatic disorders should present evidence of aggression, latent or manifest. And sure enough, it seems that in the case-histories of such diseases "anxiety, obsessionalism, and more or less latent aggression are almost constant findings."

[1] Alstead, S. *Lancet*, 1949, i, 171.

What decides the choice of symptom? Stalker suggests a hereditary predisposition to react to stress in a specific way; but this is only to say: "The boy is asthmatic because that's the kind of boy he is." Stalker, however, is merely presenting a hypothesis about the uncharted land of psychosomatic diseases: he admits that "nearly all the laborious, careful, and detailed work of exploration has still to be done."

THE HEALTH OF WELSH STUDENTS

THE attitude of students to their university career varies considerably. A survey by Dr. R. A. N. Hitchens and Dr. Graham Grant[1] shows that a high proportion of students in the University of Wales are thought to make inadequate use of their leisure, whether in the playing-fields or in cultural pursuits. The aim of many of them is to get through their course as quickly as possible and begin to earn, so that they may cease to be a burden on their families, who are often poor. Others find sports too expensive, or have to spend too much time in travelling, or are too much afraid of failing in their examinations (and thus losing their ex-Service grants, or being called up) to spare time for recreation. Not all the constituent colleges have good facilities for sport; and some of the students are apathetic about leisure activities. "The idea seems to be widespread that single-minded attention to studies and the avoidance of leisure activities is the most efficient way of pursuing a university career." This implies a sad, and possibly narrowing, misuse of opportunity, and almost certainly has an unfavourable effect on health. The survey is the first of a series of annual reports to be made on Welsh students, and is based on the study of 1002, mostly newly entered, who agreed to be examined; they represent some 64% of the whole entry.

Any deviation from the normal (however slight) which might have an adverse effect (however slight) on the student's health was noted as a defect; and on this criterion defects averaged over 2 a head. Psychological disturbances were found to be few and mild. Among the student population of all years the incidence of tuberculosis—as gauged by mass radiography—was low (0·7%); but only 3240 out of 5095 agreed to be examined, the proportions ranging from 49% in the University College of Wales, Aberystwyth, to nearly 80% in the University College of South Wales and Monmouthshire and the College of the Domestic Arts, Cardiff. At two of the colleges the students were Mantoux-tested, and next year this is to be done in the other colleges as well. Dr. Hitchens and Dr. Grant suggest that recreational opportunities might be improved, and they hope to develop health education through small group discussions.

Alstead, S. *Lancet*, 1949, i, 171.

wards or the department concerned rather than with a geriatric unit. This winter we hope to start admitting new cases and to have an outpatient department or at least an organised follow-up clinic.

The recognised authorities on the medical care of the elderly all agreed that any geriatric scheme will collapse unless the hospital unit has access to sufficient resident homes and long-stay annexes. Lack of these is one of our greatest handicaps in Northern Ireland. The voluntary residential homes have long waiting-lists and naturally tend to pick out the most active and medically fit applicants at their periodic "elections." Long-stay annexes do not exist (except in the few workhouses that remain), and we have not so many large houses suitable for conversion as there are in England. We do succeed in sending a fair proportion of patients home, to voluntary resident homes, or to the welfare wards of the old workhouses when they are fit to go out, but the lack of long-stay annexes is the real difficulty. Last year we sent a considerable number of patients to an annexe in another hospital 35 miles from Belfast which was used as an evacuation centre during the war, but that outlet will shortly be closed when that hospital takes over those wards for its own use.

There is little hope of any immediate solution to these difficulties, but the newly formed welfare authority is working in liaison with the Hospitals Authority on the social problems of old age, and it is hoped that in the next few years sufficient homes will be established to relieve the pressure. The difficulty of disposing of our rehabilitated patients became obvious within a month or so of starting work in the City Hospital, and a suggestion was made to the Hospitals Authority that a modified survey, similar to the Rowntree report and Sheldon's Wolverhampton survey, would be of inestimable value in planning future developments from both medical and social aspects. Small independent inquiries have been made from time to time in recent years, but no coördinated information was available. The Hospitals Authority accepted the proposal, an advisory committee was appointed, and the survey began in May, 1949.

SOME PROBLEMS

Some of the problems in the wards have so far not been solved satisfactorily.

Owing to the great difficulty in finding long-stay accommodation there are many frail ambulant, bedfast, and incontinent-bedfast patients still in the wards. Following the attempt made two years ago to investigate these patients, one of the doctors tried the simple experiment of putting all the hopeless irremediable patients in one ward (60 bed [illegible] remediable and sick in another, and [illegible] in a third. The results in the first ward were disastrous, and both patients and nurses were intensely unhappy. That experiment has made me sceptical of the wisdom of giving any one group of nurses only one type of patient to look after; but, though we have distributed the burden of the irremediable patients (especially who are incontinent) among the six wards, we have solved the problem, because irremediable patients, e if grouped in special beds, inevitably distract attention from those requiring rehabilitation if nursed in the same ward. It might be best to give each sister two separate wards and enough nurses to run one as a rehabilitation ward and the other as hospital long-stay accommodation, changing the staff at intervals so that they have their fair share of each.

TABLE I—ANALYSIS OF DISCHARGES

Type of patient	Total no. in hospital in August, 1948	No. discharged to				No. died	No. remaining	No. readmitted
		Own home	Resident homes	Long-stay annexe	Mental hospital			
Elderly infirm	58	7	20	10	2	8	11	3
Remediable ..	67	14	6	5	..	7	35	3
Irremediable	107	6	4	6	4	29	58	..
Psychiatric ..	78	3	9	6	17	17	26	1
Total ..	310	30	39	27	23	61	130	7

We have not decided what to do with those patients one regards as "frail ambulant"—e.g., hypertensive failure requiring digitalis; diabetics requiring insulin; and recovered but frail hemiplegics. Should these remain under hospital care (long-stay annexe or otherwise) or should the welfare authority make provision for them?

There are always one or two patients who, though not certifiable, are a constant nuisance in the general wards. They may be rowdy, abusive, fond of "baiting" other patients, actively uncoöperative, or ready to make trouble at the slightest provocation or even without it. Often they have been turned out of their homes by relations who have had more than they can stand of their antisocial behaviour, and if they have an irremediable complaint and cannot leave hospital they present a very difficult problem in management.

I have not given any statistical details of incontinence in this series of patients, but our experience has been similar to that of other geriatric physicians. Most of those incontinent patients who were enabled, with treatment, to get up, if only to sit in a chair, became free from incontinence while up, but very many of these are still incontinent at night when they return to bed. This nocturnal incontinence still awaits a solution. Some of these cases may respond to Wilson's cystometric technique when we start this treatment. Urinary incontinence is three times more common among our female patients. Fæcal incontinence is relatively uncommon since we introduced periodic enemata each week in those complaining of this condition, with regular bed-pan rounds and careful supervision of the patients while they are in use.

TABLE II—RECLASSIFICATION OF CASES

Type of patient	No. in August, 1948	No. in June, 1949	No. transferred from			
			Elderly infirm group	Remediable group	Irremediable group	Psychiatric group
Elderly infirm	58	41	..	14	14	1
Remediable ..	67	9	1	..	1	..
Irremediable	107	72	..	15	..	13
Psychiatric ..	78	17	1	..	2	..

RESULTS

The statistics which follow show the results of the work in the convalescent buildings of the Belfast City Hospital from August, 1948, to July 31, 1949.

There were 310 patients in the wards—154 men and 156 women. The average age of the male patients was 71 and of the female 74; 27% of the men and 35% of the women were aged 80 or more; 50 men (32%), and 55 women (35%) were ambulant (implying various degrees of activity from ability to get up and help to carry food and do "chores," which applied to one or two patients in every ward, to being able only to walk out to the annexe when necessary). 19 men (12%) and 37 women (24%) were incontinent.

These patients were grouped according to the B.M.A. classification as follows:

Elderly infirm	Remediable sick	Irremediable sick	Psychiatric
58	67	107	78

BLE III—LENGTH OF STAY IN HOSPITAL OF PATIENTS DISCHARGED

ither harged	Length of stay in hospital							
	Less than 1 month	1–5 mos.	6–11 mos.	1–2 yr.	3–5 yr.	6–10 yr.	11–20 yr.	More than 20 yr.
.. ..	2	5	3	3	6	1	..	1
t home ..	2	8	2	4	1	3	..	3
ay annexe	..	1	1	2	2	2	..	..
tal ..	4	14	6	9	9	6	..	4

the following 12 months 180 patients left the , as follows:

	Resident home		*Long-stay annexe*		*Psychiatric (mental hospital)*	*Died*
	Welfare	*Voluntary*	*Frail ambulant*	*Bedfast*		
..	23 ..	16 ..	21 ..	6 ..	23 ..	61

ls of discharges from the different groups are given le I, from which it will be seen that 22% were rged either to their own homes or to resident , and 16% to long-stay annexes or to a mental al: 19% died; and 43% remained.

patients from the original series who remained in ards at the end of the year were reclassified, and II shows the figures for June, 1949, compared with for August, 1948, for the different groups, together the numbers of patients transferred from one to another. It is an interesting reflection on one's y to estimate the potential capacity of an "old r" in the chronic wards to see that 14 patients were considered to be "irremediable" bedfast in August, 1948, are now classified as "elderly ," which means that they have recovered suffi- y to be up, dressed, and walking about for the er part of the day. In addition to these patients ore so-called "irremediables" were discharged or to resident homes (see table I). On the other 15 patients originally considered to be "remedi- have not responded to treatment and are now ded as "irremediable." The 12 patients transferred the "psychiatric" group to the "irremediable" are not certifiable but have mild degrees of ent cerebral incompetence.

ABLE IV—ADMISSIONS AND DISCHARGES IN A YEAR

ted	No. discharged to						No. died
	Own home	Resident home	Long-stay annexe		Mental hospital	Elsewhere	
			Frail ambulant	Bedfast (voluntary)			
	119	24	6	2	15	5	83

ecords in the early months were incomplete, and s accompanied some transfers to other institutions: e dates of admission have still to be traced for all original 310 patients. The length of stay in hospital 75 of the original patients was as follows:

Stay in hospital	*Men*	*Women*	*Total*
Less than 1 month	5 ..	5 ..	10

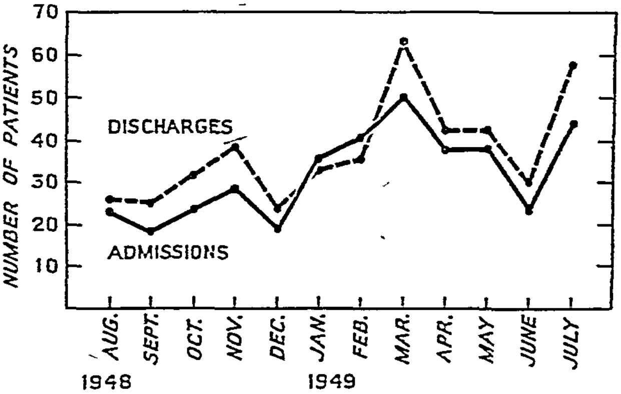
The length of stay in hospital of 52 of the original patients discharged home, to resident homes, or to a long-stay annexe for frail ambulant patients is shown in table III. These discharges are distributed over all the groups whose stay in hospital is given above, and not to most recent admissions alone. Four patients who had been in hospital for more than 20 years were fit for discharge home or to resident homes.

The accompanying figure shows the gradual rise in the rate of admissions and discharges to the wards over the twelve months. During the early months beds were being reduced in the wards to relieve overcrowding. The peak in March is explained partly by the fact that about that time a considerable number of patients went out who had required little more than encouragement and social readjustment to enable them to leave hospital, and partly by the good weather and the approaching spring, which invariably stimulates the old lodging-house inmate to bestir himself and leave his winter-quarters in hospital to spend the summer elsewhere.

Finally, table IV shows the results obtained with the new patients admitted in the past twelve months. It will be seen that out of 382 patients aged 60 or more admitted to the geriatric unit 40% were discharged home, to resident homes, or to long-stay annexes, 22% died, and 5% were discharged to a mental hospital or to other hospitals for some specific reason; 33% remain either under treatment still or in the long-stay wards of the geriatric unit: 3 patients were readmitted.



Admissions and discharges.

Experience in the pioneer geriatric units in England has shown that their figures for discharges home or to resident homes, and deaths among patients aged 60 or more admitted to their wards, correspond very closely—about 40% may be discharged, and 40% may die in a year, leaving about 20% as a "residuum" for whom the hospital will require beds in a long-stay annexe. Our death-rate of 22% is very much lower, but this may be explained by the fact that our admissions were selected from patients in the general wards of the hospital—either remediable cases or irremediable "long-stay" cases—and many elderly patients died in the general wards who would have been included in our figures had we been taking direct admissions. This also explains our greater "residuum" (33%) which is aggravated by the lack of long-stay accommodation for frail ambulant patients.

I wish to thank the Northern Ireland Hospitals Authority for permission to publish this paper. The work was made possible by the courtesy of Dr. J. C. Davison, and I am indebted to the doctors and nurses of the "convalescent buildings" for all they have done to achieve these results and start a geriatric unit; to Miss E. M. Sargaison for her help with the tables; and to Dr. Marjory Warren for much helpful advice and encouragement.

CHRONIC SICK AND ELDERLY IN HOSPITAL *

CONCLUSIONS FROM A BRADFORD SURVEY

PETER McEWAN
M.A., M.B. Edin., F.R.C.S.E.
CONSULTING SURGEON, BRADFORD ROYAL INFIRMARY
S. G. LAVERTY
M.B. Edin., M.R.C.P.
MEDICAL REGISTRAR, BRADFORD (B) HOSPITAL MANAGEMENT COMMITTEE

NEARLY all the 701 patients examined and classified in our survey are the final result of the hospital system of the past, which is now, we hope, nearly at an end. They are decrepit in mind and body. Their mental activities have decayed and they are dull, listless, and apathetic. Their joints are often stiff and painful, and their muscles weak. Everyone, themselves included, has regarded them as hopeless and useless, and that is just what they have become. This group has furnished us with many useful lessons of what not to do. Even for these patients, as they are today, much can be done. The old atmosphere of gloom and apathy can be changed and their outlook made brighter and happier, and many can enjoy getting about again, though the cure ratio must be small. The chief aim of a geriatric service in the future must be to keep the elderly from falling into this hopeless state.

A second group, near neighbours to the first, consists of the ambulant elderly in the public-assistance institutions. These act as feeders to, and are to some extent interchangeable with, the bedridden chronic sick. The ambulant group is under the care of the local health authorities. It is important that their medical attendant should in future work in close liaison with the medical officers of the geriatric hospital.

These two groups constitute a very small proportion of the elderly people of the nation, the vast majority of whom live at home. In Wolverhampton, for instance, Sheldon[1] found that only 2% of the elderly were in institutions, and 98% lived at home. There are three main reasons why the latter have not so far flooded these beds. First, there are no spare beds; they are crowded out. Second, the hospitals are not popular owing to the low standard of efficiency. Third, there is still a strong family bond of affection, and many relatives like to care for their old people and the old people cling to home. At the same time, some of the aged are a heavy burden; in Sheldon's survey $2^1/_2$% were bedridden and a further $8^1/_2$% were unable to stir outside the home. Many of these patients ought to be cared for in institutions or hospitals in simple justice to their heavily burdened relatives.

There is, however, a real and serious danger that if enough hospital beds were available and the medical services of good quality, admission would be claimed for a very large number of the elderly. So many of them suffer from disabilities, major or minor, against which they struggle bravely, that a great waiting-list for the hospitals could easily and legitimately be formed. This would be a calamity from every point of view. Home is the proper place for the aged. It is there that their roots are deeply implanted; their interests, their relatives, and their friends are there. They know every step of the house and can walk about with safety. They can be useful in many ways; indeed the grandmother can rear a second family and set free the intermediate generation. They have a sense of independence. If they are uprooted and go to hospital, all these assets vanish and often, as is well known, a rapid decline, physical and mental, takes place.

Further, it is of great importance not to family bond. Once the family link is broken, it difficult to restore. Sheldon lays great stress family affection and devotion; but however may have been of Wolverhampton in 1946–47, investigation gave clear proof that in Bradford in many old people are not wanted at home, and confirmed by family doctors. The reasons are many varied. One potent reason is the shortage of accommodation and consequent overcrowding; " age and youth " cannot live so close together times one is tempted to say " age and crabbed y The care of the aged may be a heavy task: the of making them comfortable may upset the budget, and curtail beer, tobacco, and the Occasionally, old people are not liked at home their " bad habits " are disagreeable and so detrimental to the children. In Bradford, the ment of female labour in the textile industry difficult to look after either old people or babie home. In addition, there is the Spirit of the Age, individualism and tending to throw all burdens State, thereby weakening the sense of family bility, unity, and cohesion. If once it were to fashionable to transfer the care of the elderly f family to the State without loss of face and w guilty conscience, a very big hospital and socio e problem would confront the community.

SUGGESTIONS FOR A GERIATRIC SERVICE

Can a geriatric service be devised which wi the elderly to spend their latter days in health a and happiness at home? There are two ways it could give valuable aid.

First, the geriatric service can, by an outpatien physiotherapeutic) department, enable many people to maintain a good enough state of healt mobility to avoid the need for coming into Painful feet, occurring in 38% of the elderly, and joints, are common disabling conditions, ca being greatly relieved. Efficient transport will be and an outpatient department free from draugh chills, falls, and fatigue, especially in winter, m than undo any benefit received.

Second, the geriatric service can deal, di indirectly, with socio-economic difficulties in the such as finance, shopping, queueing, laundry, in the house. For people living alone without help, meals by mobile canteen may be transp the home. Here an almoner service is of great va for patients and for old people with purely difficulties. Almoners could probably be reinfo voluntary helpers. The almoner should have sphere both within and without the hospital. Sh for example, imbue the relatives and patient outset with the idea that the hospital is only a te residence and that the patient as soon as fit will home. The doctor and the almoner should be touch because the medical and socio-economic are closely interlinked: often they should see the together so as to survey the whole picture.

Much care should be taken in the selection of There will be a group which should be admitted delay, including:

Patients in terminal conditions whose relatives a to look after them at home.

Senile mental confusion states which require adm prevent the ignominy of mental certification at an age.

Patients whose home-nursing is a real hardship to particularly where there is heavy incontinence.

Patients who would be alone at night if left at h

Sick patients who will benefit from hospital treat cannot be satisfactorily treated at home or as out even with the aid of transport.

---

* Abridged from the concluding section of a report to the Bradford (B) hospital management committee. Copies of the report (5s.) may be had from the secretary of the Committee, Midland Buildings, 12, Canal Road, Bradford.

1. Sheldon, J. H. Social Medicine of Old Age. London, 1948.

these exceptions, most patients should be seen by riatric doctor either in the outpatient department, ng with the family doctor at home, so as to decide er treatment at home or as an outpatient will be iate. The hospital waiting-list should be carefully igated with the object of keeping out all patients do not need, or no longer need, admission. The of a geriatric hospital is thus intimately linked up the responsibilities of the local authorities, and a a should be arranged so that they work hand in hand.

A GERIATRIC HOSPITAL

s us now turn to the principles which should be ved in setting up a geriatric hospital.

e service centres on the efficiency and devotion of ief medical officer. It does not much matter whether a physician or surgeon or orthopædic surgeon or other qualifications. He must, however, be fully inted with the possibilities of modern treatment e elderly, the good results now obtainable, and the ods employed. He must be prepared to give idual care, or see that it is given, to each patient. a medical officer will inspire confidence and obtain siastic coöperation. He will win all concerned to ng for the work—sisters, nurses, orderlies, physio-pists, occupational therapists, almoners, and last not least the patients themselves and their relatives. od geriatric hospital is a happy place.

eatment should begin early in the course of a disease, in inpatient and outpatient departments, and nts should not be neglected after treatment ceases, ant of a follow-up. Relapses should be treated early. ring their stay in hospital patients should, if ble, remain in the same ward under the same sisters nurses, and they should certainly remain under the doctor. This ensures continuity of treatment, and ases the doctor's sense of responsibility; his interest res confidence in the patient and avoids the unneces- and wasteful labour entailed if a fresh medical officer o investigate and understand the case anew.

e chief medical officer should have available to him ervices of consultants and X-ray and pathological ties. It is desirable to have together under one roof least connected by covered way the following parts e hospital:

gistration and record room, doctor's room and examina-rooms, X-ray rooms, pathological rooms, physiothera-c unit, occupational therapy department, almoners' mmodation, waiting-room for patients and friends, en, typists' room, accommodation for coats and hats, accommodation, possibly an injection and dressing dispensary.

block should have a non-slippery floor, be well ed and ventilated, be free from draughts, and have on the walls to help the elderly in walking.

he question of grouping together patients suffering the same disease was considered. It appears better te treatment wards to arrange them according to ect of ultimate recovery, with a favourable ward a ward for less favourable cases. Separate wards required for the mentally confused and for the tinent, and patients who are bad influences in a d and those of dirty habits should be segregated. Some mmodation should be reserved for those about to die. atients should not be discharged home without first ing through a ward in which they can spend an active od to better-fit them for home life.

ards should be bright and airy, with flowers and eful decorations, and there should be diversions such music, concerts, or films. Occupational therapy fills ace. If tasks are useful and earn a reward, this is an ellent incentive. A day room and recreation room desirable.

he usefulness of a hospital depends partly on its turn-r. Patients pass more slowly through a geriatric than through an acute hospital, but they must pass through. About a third die in three months from admission, a third go home, and the remaining third must not be allowed increasingly to block the hospital; they must gradually pass on to hostels if well enough or to long-stay annexes or less active hospitals. Nurses should interchange to some extent. This will keep up the standard of the less active hospitals for the elderly. It will be good for nurses in training in acute hospitals to have some experience of geriatric nursing.

GERIATRICS AS A SPECIALTY

Thomson [2] stresses the necessity of bringing the aged chronic sick into the main stream of medicine, admitting them to the general hospital wards for accurate diagnosis and thorough treatment. He does not believe that geriatrics should be made a specialty, but considers that the treatment of these patients should fall to the general physician. While conceding that many aged patients will continue to need general hospital accommodation we are in favour of a specialised geriatric service, for many reasons.

The existing clinics where geriatric patients are successfully treated are in the charge of doctors who have developed a special interest in the work and who are in fact geriatric specialists. The long-term illness from which most of these patients are suffering requires the intensive and persistent application of medical treatment and nursing care. This is more likely to be given in a centre devoted to geriatric problems. The work appeals only to certain physicians and surgeons. In a general hospital ward geriatric cases may be easily relegated to an inferior status as of less interest than acute cases, and slower in their response to treatment.

Again, the number of potential patients who can be given treatment, and who can be prevented from entering hospital, by an efficient geriatric outpatient service is large enough to justify the geriatric specialty. We also hold that continuity of treatment is essential in these cases and can best be obtained by a special service whose medical officers supervise treatment and assess progress over long periods.

The pendulum at the moment has begun to swing strongly in favour of better treatment, medical and socio-economic, for the increasing number of elderly people of the nation. It has not yet swung nearly far enough, but care must be taken, if the total amount of hospital accommodation is limited, not to deprive the younger, active, working, and therefore more valuable individuals of the facilities for speedy restoration to work, by transferring too many old people permanently to hospitals, institutions, and hostels. This complex problem, many aspects of which have been discussed in our report, will ultimately reach a state of equilibrium which will give as full expression to the national instinct of human kindness as economic conditions will permit.

RESOLUTIONS ON REMUNERATION

AT a meeting on Dec. 1, the General Medical Services Committee considered the Minister of Health's refusal [3] to increase the amount of the central pool for the remuneration of general practitioners. The committee passed the following resolutions:

1. That in the view of the committee the reply of the Ministry of Health dated Nov. 14 to the request of the conference of the local medical committees for a recalculation of the central pool in the light of the facts now available is entirely unsatisfactory, and that an interview be sought to demonstrate its inaccuracies, to calculate the sum by which the central pool is short, and to reiterate the demand for an adjustment of the central pool to meet this deficiency.

---

[2] Thomson, A. P. *Brit. med. J.* July 30, p. 243.
[3] See *Lancet*, Nov. 26, p. 1005.

2. That before the January meeting of the General Medical Services Committee an assurance be sought of the Ministry of Health that the central pool will be continuously adjusted so as to maintain in the future—whatever the changes necessitated by the heavy burden of work falling on general practitioners and whatever the increase in the number of doctors—the levels of remuneration recommended in the Spens Report which were accepted by the Government.

WELLCOME HISTORICAL MEDICAL LIBRARY

THE reopening of this library was celebrated on Dec. 2 at a luncheon attended by librarians and bibliophil doctors. Presiding as chairman of the Wellcome Foundation, Mr. H. Sier welcomed the guests, who returned thanks through Sir Arthur MacNalty and Sir Henry Thomas. Dr. E. Ashworth Underwood, director of the Wellcome Historical Medical Museum and Library, gave an account of the library and its origin.

It was founded by the late Sir Henry Wellcome to provide a comprehensive collection for students of the history of medicine and the allied sciences, and has been built up over the past fifty years by purchase at public and private sales, supplemented by gifts and bequests. It now contains about 200,000 printed books, pamphlets, and journals; 5000 manuscripts; and 100,000 autograph letters of medical and scientific interest, as well as other documents. Almost all the landmarks in the history of medicine are represented by original texts.

Of *books printed before 1500* (incunabula) it possesses 612 complete works and 22 fragments. This is one of the largest collections of medical incunabula in the world, its nucleus being formed of accessions from three famous private libraries,—those of William Morris, Dr. J. F. Payne, and Kurt Wolff—together with a smaller number from that of Prince Dietrichstein. A detailed catalogue will soon be in the press.

The *sixteenth-century books* number over 4000, with 700 English books printed before 1640, some of which are not to be found elsewhere outside the British Museum.

The library contains more than 10,000 books printed in the *seventeenth century*. From this century onwards all important advances in medicine and science are signalled by original texts. There is also a wealth of less well-known clinical and scientific material, including a wide range of early periodicals, which awaits the notice and study of the historian.

The library is very rich in *special collections*. In addition, there is a very comprehensive collection of modern *bibliographical and reference works*, so that only rarely need a reader look elsewhere for information on any topic. Current periodicals and new books dealing with the historical aspects of medicine and the sciences are acquired as they appear.

The *autograph letters*, which number more than 100,000, are still largely unexplored. The library also has a large collection of *Oriental manuscripts* and many modern printed works in the Oriental languages.

The task of cataloguing and arranging so vast a collection has hitherto occupied the full energies of the staff, and post-war conditions have made equipment and furnishing very difficult. But some temporary expedients have been adopted which will now enable the library to fulfil its function as a centre of medical and historical research. It is open at the Wellcome Research Institution, 183, Euston Road, London, N.W.1, from 10 A.M. to 5 P.M., from Monday to Friday throughout the year, except bank holidays. No books can be lent, but prints, lantern slides, and photostats can be supplied, and there is also a microfilm service with a reading machine. A general catalogue in short-title form is now being prepared for the press.

Historical and bibliographical inquiries can be dealt with by the staff: they should preferably be made by letter, but in exceptional circumstances requests for information by telephone will be accepted. Exhibitions will be held from time to time, and conducted visits for special parties can be arranged with the director or the librarian, Mr. W. J. Bishop.

THE ROYAL FACULTY CELEBRATES

FROM A CORRESPONDENT

DOCTORS are alleged to be excessively jealous of traditions and privileges, and in northern latitud be a bonny fighter is a coveted title. In the celeb of the 350th anniversary of the Royal Faculty of Ph cians and Surgeons of Glasgow, it was obvious the temper of the fellows is militant as well as jub There were frequent reminders of past relatio between the Faculty on the one hand, and the Cl the University, contemporary professional institu and the city fathers on the other. The Faculty day has crossed swords with most of these bodies northern kingdom, and has displayed the qualit resourcefulness and doggedness which spring fr realisation that the privileges of the Faculty are in able from responsibilities. This was the centra which guided the Faculty during its long peri professional jurisdiction over an area of Scotland a identical with that now entrusted to the W Regional Board, and its influence in the 17th and century was far-reaching, as described in these co on Nov. 26.

SERMON

The Minister of Glasgow (the Rev. Nevil Davidson preached the sermon at the cathedral service of comm tion, reminded the fellows that the Church had pr the pioneers who tended those sick in body or in Basing his observations on the text: "I am come tha might have life, and that they might have it more abund he emphasised that the Church today is still deeply con with physical as well as with spiritual health. Dr. Da also urged the president and fellows to consider whe might not be possible to achieve a greater measure of boration between the minister of religion and the m practitioner, suggesting that the means of achievin liasion might be examined at a joint conference of th professions. The service was concluded in the churc where the president, Dr. W. R. Snodgrass, placed a on the tomb of Dr. Peter Lowe while a snell wind merry with gowns and hoods.

HONORARY FELLOWSHIPS

In the Faculty hall on Nov. 28, honorary fellowship conferred on Emeritus Prof. E. P. Cathcart, F.R.S., Em Prof. G. B. Fleming, Sir Hector Hetherington, Prof. H Lloyd, F.R.C.O.G., Lord Moran, P.R.C.P., Dr. R. Barclay Dr. W. D. D. Small, F.R.C.P.E., Sir Cecil Wakeley, P. Mr. W. Quarry Wood, F.R.C.S.E. The ceremony took pl the large hall, which was crowded to the doors and dow main staircase by the fellows and their guests. It most impressive and colourful ceremony. The hon fellows were introduced by the learned clerk of the Fa Mr. T. L. Grahame Reid, whose orations though brief as vivid as they were felicitous. After the confer congratulatory messages were presented by the pres of the sister corporations of the United Kingdom and t Principal of the University of Glasgow. Professor Cat thanked the Faculty on behalf of the honorary fe Pointing a warning finger at the principal of Gl University, he explained to Sir Hector Hetherington tha honorary fellowship did not entitle him to practise physi

DINNER

The celebrations were rounded off with a dinner in faculty hall on Nov. 29—the penultimate day of the m mentioned in the charter 350 years ago. Wit and inge were well matched in Prof. G. B. Fleming's comprehe speech when he toasted The Guests. The Lord Pre replying for the guests, expressed the pride which the felt in having such a lively Faculty in its midst, an personal relief that the fellows were too well behaved vidually and collectively to be a source of trouble to magistrates. He attributed to Professor Fleming the wr of the very attractive prescription that appeared on menu card and which included Amontillado, Chateau Le Barton 1934, Clicquot 1937, and Cockburn 1927; adding he felt that the time had come to transfer his Nati Health Service card to Professor Fleming's file. Sir He Hetherington, proposing the toast—The Royal Facult Physicians and Surgeons—said that the old feud bet y and University was long past and only of historic t. But the Faculty still had a very important part r in fashioning the National Health Service. He added at there were movements afoot in medical education, lly in postgraduate education, which made it imperative he Scottish corporations and the Scottish universities keep the subject under continuous examination.

COMPLIMENTS FROM THE CITY

close relationship, harmonious and otherwise, that has s existed between the Faculty and the Town Council raciously acknowledged by the Lord Provost and ration of Glasgow at a reception held in the city ers. Acknowledging this happy gesture, Mr. Walter ith (visitor) pointed out to the Lord Provost (Mr. Warren) that in receiving the Faculty so hospitably orporation were faithfully observing the injunction ned in the charter wherein the bailies were instructed sist, fortify, concur and defend" the brethren of the ty. On the following day the Faculty returned the iment by entertaining a number of representatives of rporation at a luncheon in the Faculty hall. As a further of good will the corporation organised an exhibition licine in History" at the Art Gallery, whose director Thomas Honeyman, F.R.F.P.S., commemorating advances dicine and surgery with particular reference to the layed by the Glasgow school and fellows of the Royal ty of Physicians and Surgeons.

MEDICAL RESEARCH AT HOSPITALS

E Ministry of Health has sent the following memo- um to regional hospital boards, boards of governors, management committees :

> The Minister has had under consideration, in consultation the Medical Research Council, the general policy which d apply to the promotion of medical research at hospitals. ls and committees will be aware that Section 16 (1) e National Health Service Act, 1946, extends the powers e Minister under the Ministry of Health Act, 1919, to e him to conduct, or help others to conduct, research any matters relating to the causation, prevention, osis, or treatment of illness or mental defectiveness; hat Section 16 (2) of the Act confers similar powers to act (but not to help others to conduct) research, on nal hospital boards, boards of governors, and hospital gement committees.
>
> The constitutional position of the Medical Research il enables that body to promote a wide programme of rch in medical science, free from territorial or adminis- ve limitations of function, and to coöperate with all rnment departments concerned in any way with practical lems of health. In exercising its own powers, the Ministry hitherto in practice confined itself to promoting such tigation as can best be done within the framework of ealth services for which it has immediate responsibility. Council has been left with the wider, and particularly the term, problems of medical research: these include y which fall administratively within the scope of rtments other than the Ministry of Health.
>
> The fact that the Minister is now responsible for the ital services does not in his view, and that of the Medical arch Council, involve alteration of the principles governing agreed division of functions as regards promotion of rch. It is recognised that a good deal of research work ow being carried on in hospitals (apart from research ied out by medical schools and postgraduate institutes which the Minister is not financially responsible) and Minister does not propose to ask boards and committees ost this separately at this stage. He thinks it right, ever, to ask boards and committees not to promote any research work involving additional expenditure from r ordinary budget without his prior approval, in order he may consult the Medical Research Council and re a proper measure of coordination. So far as research nced from "free monies" is concerned, the Minister has desire to interfere with the discretion of boards and mittees in this matter; but he would be glad if they ld indicate in broad terms each year when submitting ir accounts the research projects on which free monies are ng spent and the amount of the expenditure involved.

Parliament

Corrective Training

IN raising this question in the House of Commons on Dec. 2, Mr. J. C. MAUDE, K.C., said that probably the one outstanding feature of the new Criminal Justice Act, which gave hope of better things by way of the reformation of prisoners was the provision for corrective training. He did not blame the Home Office because they had not been fully prepared to put this provision of the Act into operation. But he did want the judiciary, when they sentenced men and women to corrective sentences, to know exactly what those sentences meant. On Oct. 4, of the 732 men and 36 women prisoners who had received sentences of corrective training, 389 men and 8 women were in fact in local prisons. Mr. Maude suggested the Lord Chancellor and the Home Secretary might arrange for private meetings, at intervals of two years or less, where the Judiciary, including recorders and chairmen of quarter sessions, would hear from the Prison Commissioners how far it was thought they were being successful with their sentences, and in what way they could improve them by being instructed in a certain amount of follow-up information on the cases. He believed that unless there was a stronger link between the prison commissioners and the Judiciary, the time would come when we would find the present system to be hopeless. The proper thing was to have indeterminate sentences, so that a judge passed a sentence that a man was to be detained for a period, and some other body decided exactly how long the period should be.

Mr. GEORGE BENSON believed that the whole corrective training experiment was in danger of breaking down under the weight of the sentences passed. Something like 900 sentences of corrective training had been passed in a few months, and the Prison Commissioners were incapable at present of dealing with more than a fraction of that number. A large proportion of the corrective trainees would have to be accommodated in local prisons where any attempt at training was little more than a farce. Again, sentences of preventive detention, which might range from 5 to 15 years, were not imposed for punishment but for the purpose of safe custody. It was outrageous to impose these sentences unless custody was vastly different from ordinary prison conditions, yet under the dual-track system adopted by the Prison Commissioners a portion of preventive detention must be served in a local prison. Follow-up, he continued, was the key to any increase in accurate knowledge with regard to sentencing and the treatment of delinquency. But some years of intensive research were required, based on accurate information as to what happened, not merely to delinquents in bulk, but to specific types. There had been a certain amount of background research in juvenile and adolescent delinquency, but what was really needed was a carefully controlled system of follow-up and the application of a scientific system.

Mr. K. G. YOUNGER, under-secretary of State for the Home Department, in his reply, agreed that preventive detention was essentially a preventive measure, though as much training and reformative treatment as possible was incorporated. The initial stage was served in a local prison, but the remainder of the sentence would be spent at a central prison, which it was intended should be Parkhurst. During their last year suitable prisoners would undergo a course of readaptation for civil life at some new establishment which did not yet exist. As the system only began in April and the minimum sentence was 5 years this was not yet urgent.

Most of the people sentenced to the new form of corrective training were people with a considerable number of convictions. The object of the training was to give a sense of responsibility, and the main method used was a hard day's work, with the satisfaction that came from it; particular effort was made to make it useful work. The trainees also got vocational training and facilities for education superior to what they would get in an ordinary local prison. Moreover, they got a good deal more free association at meal times and at times of recreation.

As there was no spare space in prisons when this system was introduced, the Prison Commissioners could not be expected immediately to make suitable provision for the large number of people sentenced. Chelmsford prison was ready for 208 people when the system was introduced. Since then two wings at Liverpool prison took 221 people, and one wing at Wormwood Scrubs a further 340. That made a total of 829 as against the 1028 who had been sentenced. It was hoped to add another wing at Wormwood Scrubs and an open camp to relieve the present congestion. The Home Office and the Prison Commissioners were anxious to give the courts every help they possibly could. But such guidance must wait to some extent on experience. None of these people had been undergoing this treatment for more than six months. Some were certainly not responding freely to it; though even then it did not follow that on the information available it was unreasonable for the court to decide to give this form of sentence. Sentencing was a matter for the courts, and all that the Home Office could do was to submit reports and information, and, if asked, to give advice and make recommendations. The final judgment must rest with the courts. There was no objection of which he was aware to the holding of conferences as had been suggested by Mr. Maude.

Mr. Younger pointed out that corrective training was a vague and indeterminate subject which lent itself much less readily to scientific research than, say, a physical ailment. While he believed that a scientific method could be applied to this problem they had been obliged to avoid launching large and expensive schemes of research; but the Home Office was at present considering what they could do to improve, both on the statistical side and on the side of case work, following through the individual cases from the court to the training and to the results of the training.

Amending Act

In the House of Lords on Dec. 1 the National Health Service (Amendment) Bill was read the third time and passed.

QUESTION TIME

Selection of Medical Students

Mr. PHILIP PIRATIN asked the Secretary to the Treasury what were the qualities sought for by the boards of medical schools in determining the suitability for the medical profession: and if he was satisfied that these qualifications, other than scholastic, were such as did not prejudice the acceptance of working-class students.—Mr. GLENVIL HALL replied: The selection of candidates is entirely a matter for the authorities concerned and the medical schools are no exception to this general rule. I have no reason to suppose that the basis of selection adopted is in any way prejudicial to students from working-class homes.

Committee on Industrial Health

Viscountess DAVIDSON asked the Prime Minister if he would add a State-registered nurse to the committee on Industrial Health Services, the membership and terms of reference of which were announced on June 1, 1949.—Mr. C. R. ATTLEE replied: I have appointed Miss M. M. Edwards, M.V.O., S.R.N., S.C.M., director of nursing services, King Edward's Hospital Fund for London, and Miss E. M. Gosling, S.R.N., S.C.M., of Unilevers Ltd., to be members of the committee.

Hearing-aids for Scotland

In answer to a question Mr. ARTHUR WOODBURN, Secretary of State for Scotland, stated that the rate of issue of 'Medresco' hearing-aids in Scotland was now about 360 aids per month. Over 3500 in all had already been supplied.

St. Luke's Hospital

Mr. F. E. NOEL-BAKER asked the Minister of Health whether he would arrange with the regional board to make available to the governors of Queen Charlotte's and Chelsea Hospitals a part of St. Luke's Hospital for teaching purposes.—Mr. ANEURIN BEVAN replied: I am aware of the need for additional accommodation at the Queen Charlotte's and Chelsea Hospitals. It will probably be impossible to make any part of St. Luke's Hospital available for this purpose, but I am considering other possibilities.

Diabetic Chocolate

Commander A. H. P. NOBLE asked the Minister of why there was a shortage of the rationed chocolate prepared for diabetics.—Dr. EDITH SUMMERSKILL The supply of diabetic chocolate is limited by the of sorbitol which is an essential ingredient. I am there is little prospect of obtaining additional

Handicapped Children

In answer to a question Mr. GEORGE TOMLINSON, of Education, stated that the numbers of ch from hearing defects and speech defects noted at inspections during 1948 were approximately 19,000 20,000 respectively.

Mr. F. W. SKINNARD asked the Minister wh regulations permitted local authorities, which could present provide sufficient places for mentally seriously retarded children, to reimburse parents who their children to private clinics and occupational Mr. TOMLINSON replied: The Education Acts prohibit education authorities from incurring expenditure on defective children, that is to say children found to be able, and they are therefore not concerned with the ments made for the care of such children in occup or otherwise. For educationally subnormal children, my approval, some use is made of independent school of home tuition in appropriate cases. The Acts parents to make their own provision for these children is satisfactory, but if the authority is asked to take fin responsibility it is for them to consider what educat provision is appropriate in the light of the available faci

School Dental Service

Mr. PHILIP PIRATIN asked the Minister what ratio be laid down of school dentists to school-children, and how more dentists would be needed to reach this Mr. TOMLINSON replied: For a complete service of inspection and treatment, it is estimated that a ratio of 1 dentist to 3000 children would probably be required January, 1949, the latest date for which figures are a the number of school dentists employed by local was equivalent to 868 whole-time officers. To give a 1 dentist to 3000 children, an additional 975 would then been required. Since then, there are indications that number has seriously decreased.

Epileptic Patients

In answer to a question Mr. ARTHUR BLENKINSOP rep The number of persons in epileptic colonies in England Wales at the end of October, 1949, was 2604.

Hearing-aids

Replying to a question Mr. BLENKINSOP stated that, Nov. 5, 39,159 patients in England and Wales had supplied with medresco aids, and the current average of issue was 1015 a week. Waiting-lists totalled about 36 The staffs of the distribution centres were being incre and new centres would be opened as soon as possible.

Treatment of Leprosy

Mr. G. C. TOUCHE asked the Minister of Health how the St. Giles Home near Chelmsford had been used for treatment of lepers, and whether during that period cases had arisen of this disease being contracted by pe in the neighbourhood.—Mr. BLENKINSOP replied: I un stand that the home has been used for 35 years and tha cases of local infection with leprosy are known.

Shortage of Staff in Tuberculosis Sanatoria

Sir ERNEST GRAHAM-LITTLE asked the Minister how m hospital beds for tuberculosis patients were unoccu through lack of nurses; and what measures he was propo to take to make these beds available for tuberculosis pati in view of the rapidly rising mortality from tuberculo Mr. BEVAN replied: About 4400 beds in sanatoria tuberculosis hospitals are at present unoccupied for lack staff. Nursing staff in these institutions increased in year ended June 30 by 774 full-time and 319 part-time, in the same period 652 beds were re-opened. Apart from few slight fluctuations, tuberculosis mortality in relat to population has steadily fallen for several years past, touched a new low record last year.

In England Now

unning Commentary by Peripatetic Correspondents

E myopic Mr. Thurber has written an enchanting e about what he sees—or thinks he sees—when he nislaid his spectacles. Being hard of hearing has ar compensations for the patient if not for those ad him. Thus, it is with pleasurable surprise that arns from the B.B.C. that tomorrow's weather will unny or that he is about to listen to Vaughan-ams's "Masque of Joad." He has his disappoint-s, of course, as when his wife tells him that she is ting of biting Mary today, which would be obviously a more sensible than merely inviting her to stay; hen the rural postmistress over the telephone tells that she can't afford a piece of snoek, spurns his of financial assistance, and says that there is a call ord to see Mr. Stook. He may think his partner ly modest when he overhears him telling the patient ne next room that any fool can cure the varicose , till he finds him writing a script for penicillin

* * *

ree days out from England an American student, rning from an extensive and hectic European tour, plained of feeling seedy, and next morning there was it weakness of his left arm and a board-like feeling ss his back—that is how it all began.

is condition changed for the worse, and it seemed ible that from being a case in the medical diary he ht become an entry in the ship's log. A senior sician returning to the States agreed that an iron-lung ht be necessary, and after consultation with the ain and purser signals in code were made to the ping company's New York office. Regular bulletins wed, all help was promised, and news came through the mechanical respirator and physician-operator ested were on their way. Not until we altered course ards Halifax to rendezvous with the coastguard cutter the crew and passengers know what was afoot, and a then only by accident. "I know your little game," the bo'sun as he passed in the alleyway. "Heard it me wireless from Halifax radio: 'Iron lung and sician-operator left New York by air for Halifax ight. There they will transfer to the coastguard ter *Coos Bay*, directed from patrol, about midnight. cutter will contact R.M.S. *Parthia* about noon orrow.'" The hurricane that devastated Florida just passed to the south'ard, and there was a roughish as the cutter's skimmer came alongside next day. st the apparatus and then the personnel were hoisted ard in the "sling." The transfer took three-quarters an hour; it was quite a risky business.

Ve had no 'Furmethide' on board; so when the sician from the National Foundation for Infantile alysis thought the patient would need some he lioed for the drug to be flown to the ship. In a sur-singly short time the plane was circling overhead. had altered course so as to steam head to wind, and r men manned the derrick-cranes, each bearing a long ite pennant (in less nautical language, a piece of torn ite sheeting) to act as a wind-sock. The pilot made run-in from over the stern at mast-height and the ious package was dropped amidships, but a strong nd caught the parachute and a direct hit became a ar miss—the furmethide was in the drink! Then we e-to and a volunteer boat's crew was mustered from e watch-below. By this time the passengers who had en the morning rendezvous with the coastguard cutter ere gathering on deck and showing great interest in is latest feature of the ocean drama; but few, if any, ppreciated the risk to the boat's crew with such seas nning. The position of parachute and package was arked on the grey-blue sea by a patch of brilliant ellowish-green fluorescence which the boat soon reached. he 'chute was waterlogged and had to be hauled like big draught of fishes into the boat. They pulled back for n interminable procession of minutes, but at last they eached the safety of our lee where oil had been pumped n the waves from a hose through a low-placed scuttle. Hoist away!" The boat was safely up, and crew and package were soon inboard. The package weighed 35 lb.: six ampoules of furmethide weighted with two bricks.

In a ship one lives with one's patients and gets to see some aspects of illness familiar to nurses but not usually apparent to a visiting physician. Our patient was of more than average intelligence, he was well aware of his condition, and he knew that his companion's frenzied demand that heaven and earth be moved, that no expense be spared, that an iron-lung be flown out, &c., &c., had actually been met and the iron-lung was beside him if he needed it; he was unlikely to need it now, for there was no dyspnœa, and yet until the sedatives were increased the fear of dying in his sleep was dominant—damnably so. On the sixth day this fear seemed to leave him and he enjoyed being the centre of an "ocean drama." Afloat he was our chief concern, rather like an only child; I'm certain he felt this when he became a member of the large polio-family at the highly efficient special unit in the New York Hospital (they even have an E.N.T. houseman on duty for emergency tracheotomies in iron-lung cases!) After being the almost perfect patient, he started grumbling about having to fit himself into the schedule of hours and treatments, like a garment in the making on a factory conveyor-belt.

When we docked not only a Scully-Walton (ambulance) but a Hollywood magnum of photographers, reporters, and newsreel and television cameramen awaited us. Our guarantee of full coöperation and a press-conference secured us a calm landing. And did the boys "*go to town*"! We hit the headlines big. But the front-page scoop photograph was the gangway-shot taken by a coastguard from a nearby cabin port-hole.

The postscript came from the return trip. Steward to passenger in the dining-saloon: "No, Madam, the iron-lung did not hit the ship. If the R.A.F. had delivered it we would certainly have been sunk."

* * *

Before going down to the surgery I built up the fire and put the guard in front of it: of that I am quite certain. Nor was I smoking at the time. Ten minutes later my housekeeper, attracted by a smell of smoke, entered the drawing-room to find the rug and carpet both smouldering and the ancient chintz cover on the hassock in like case. Successfully and secundum artem she dealt with the fire. "But," she informed me on my return, "your book's ruined." "What book?" I inquired. "I dunno what book. 'Twas on the 'assick and 'tis ruined." I looked at the book and my heart sank. It was THE LANCET for Nov. 26 containing one of my own contributions. Feverishly I turned the charred pages and found, to my intense relief, that I.E.N., though as full of dry humour as ever, had survived the blaze.

* * *

This is the tale of Willie Squeers,
Who'd been at "Restham" twenty years
With one Idea fixed in his head—
That all this time he had been dead.

The Doctor, honestly no doubt,
Tried hard to root this notion out:
"Surely," he asked, "the Dead can't bleed?"
And Willie readily agreed.

"If on your finger, then, I made
A little snick with scalpel blade,
Although it possibly might hurt,
Should we expect the blood to spurt?"

"Of course not," Willie said, "I'm dry
As dust, or dehydrated pie."
But when they put it to the test,
Poor Willie bled like all the rest.

"I'm wrong," he cried, "for years on end
I must have been right round the bend;
But now, from all delusion freed,
At last I know: dead men DO bleed."

Letters to the Editor

CONTROL OF TUBERCULOSIS

SIR,—Many facets of this national problem are now coming under review, and such revision should be helpful. We are concerned to notice one retrograde proposal: the suggestion has been advanced that the chest-clinic physician should have personal control of patients under *treatment in the sanatorium, as well as* at the clinic. The sanatorium physician would thus be displaced, and daily charge of patients would be given to juniors, controlled by the occasional visit of a busy clinic physician. We feel that this policy can only endanger the good treatment of the tuberculous patient, leading finally to more delay in obtaining treatment of those yet to be diagnosed.

Tuberculosis sanatoria, except for certain small establishments, are more properly designated tuberculosis hospitals, for such a term conveys more clearly the present position of such institutions as major therapeutic agents. Modern treatment means much more than the old simple convalescent régime, as most people know; it has become an intensive process, calling specialised teams of physicians, surgeons, pathologists, and nurses. Patients have to spend much of their stay in bed; and the stay is of necessity long, lasting on average at least six months. Recent contributors have shown how effectively a certain proportion of patients can be treated under home conditions, and are being so treated. Such policies, together with advances in therapeutics which have brought *many more patients into the* "treatable" category, have inevitably tended to lengthen somewhat the stay of patients, but this has been controlled by diminishing the period of treatment in the institution when the patient has become ambulant. Nearly all tuberculosis hospitals have less than 20% of patients up for more than a few hours each day, though nursing shortage has prevented the full exploitation of bed rest, and most hospitals have perforce reduced their standard of medical treatment in this respect.

In addition to these important therapeutic functions, such hospitals have the duties of training potential specialists in the field of tuberculosis, and of postgraduate and undergraduate teaching. Further, they must constantly seek to advance medical and surgical practice in the specialty, and in many aspects this can only be done effectively by the study of sufficient numbers of patients treated in hospital.

These complex and integrated tasks can only be carried out by those who have the opportunity to keep largely to this work: they cannot be done by hurried visits from doctors who have heavy commitments in the clinics. To administer and practise in a clinic serving a population of 200,000 people is a large task, even with adequate assistance. Such a clinic has vitally important work in the environmental and the preventive spheres, and in the detection and the supervision of tuberculous persons and their contacts. Dr. F. R. G. Heaf, in his presidential address to the British Tuberculosis Association, has recently emphasised the range and importance of these tasks. *It would be a mistake if these were left* imperfectly done for the sake of undue concentration on bedside treatment of hospital patients, which is already more effectively performed by the sanatorium-hospital teams.

The tuberculosis hospital, in carrying out the work described above, becomes a unity which must not be broken. The morale and corporate spirit of such a hospital is a vital matter for the welfare of patients who have to stay so long, and we are convinced that the power and efficiency of the hospital would suffer most seriously if the skilled teams of medical staff were exchanged for large numbers of visiting clinic physicians, each in charge of a few beds. Nurses and clerical trative officers would have their work *increased and hampered by this multiplicity of* staff.

Clinic physicians generally have beds under charge in a local hospital, and such beds are a feature of clinic work. There may also be linking a sanatorium with a local clinic, but in event the area managed should be kept small and clinic would in effect be an *outpatient* depa the hospital. These are exceptions to the subject discussion, which concerns the larger sanatorium-h and large urban clinic areas.

Sanatorium staff are equally concerned with colleagues in the clinics at the longer waiting experienced by many patients. As already this is in part due to the very advances in which are doing so much to improve the outlook fo individual patient. Another important cause is continued shortage of nursing staff, who are under great pressure of work. Mutual co solving these and other problems should be a practice, but let us not impair the vitally im work of either branch of tuberculosis control.

SIR,—May I reply to some of the comments on letter of Oct. 8? While, as a sanatorium physicia naturally agree with Dr. Temple Clive's cautious atti towards collapse treatment (Oct. 22), I feel that the dismissal of any alternative to the conventional continued sanatorium treatment by him and by Dr. (Nov. 12) does not contribute towards the solutio the problem involved. On the other hand I feel strongly that, whatever are the merits and demerit domiciliary treatment with collapse and with stre mycin, the growing enthusiasm for so desperate an e gency measure should not result in acceptance of perpetuation as Dr. Heller's letter (Nov. 5) seems to im

Dr. Tattersall in his paper on Home Treatment Pulmonary Tuberculosis (Nov. 19), though giving do ciliary collapse treatment its place in an over-all p quite rightly deplores the tendency to retain patient sanatoria for many months, and Dr. Sita-Lumsde his most valuable contribution (Nov. 26) pronou that "the only possible solution of the present shortage is the acceptance by sanatorium physician a shorter stay for their patients." If, as he sugg more patients were isolated at home by the provisio open-air shelters, and if Dr. Rozner's timely suggest (Nov. 26) to utilise the idle beds of isolation hospitals the care of the chronic incurable infectious cases taken up by the authorities, an appreciable contribut to the "control of tuberculosis" would be made. *the same time a great* many precious sanatorium b could be set free for the treatable cases.

No doubt Dr. Pugh hits the nail on the head with eight points. However, his point "efficient means diagnosis at the chest clinic"—to which I should like add "and adequate facilities for modern treatment" touches a sore point *in our* tuberculosis service. necessary decentralisation of the service, with grea emphasis on the chest *clinics*, is, I am afraid, ha pered by the sorry fact that there are not nearly enou properly equipped chest clinics within easy reach of patients' homes. *It is* unrealistic to expect the gr number of obsolete dispensaries—very aptly describ strategically placed visiting stations "[1]—to be ced in the near future by modern chest clinics. a more realistic and practical point of view, there- I suggested for the time being the employment of le chest clinics[2] at places where the essential ties are lacking. With such facilities—whether onary or mobile—an appreciable number of sana- m patients, if properly selected, could be returned h more quickly to the chest physician's care without us harm. Such a practice would soon release the so badly needed for early admissions in order to "active treatment" (including streptomycin) in sanatorium rather than in the patient's home.

an alternative to the present unworkable system of -term sanatorium treatment for the few and too long a ing period for the many, such a scheme is preferable, lieve, to the courageous but undesirable expedient lomiciliary collapse and/or domiciliary streptomy- treatment. I would gladly welcome any constructive cism of the scheme which I have described in more il in the *British Journal of Tuberculosis* (April, 1949).

olywood Hall Sanatorium,
Volsingham, Co. Durham.

E. G. W. HOFFSTAEDT.

B.C.G. VACCINATION

IR,—I should like to thank those who have accepted incursion[3] into the subject of human tuberculosis such a generous spirit. May I reply to two ers?

iscussing the work of Ferguson and Simes. Prof. dford Hill (Oct. 15) asks why, "with the careful hod of allocation laid down, should 35 control infants only 2 vaccinated come into the groups watched for 15 years? Why, reversing the situation, should there 39 vaccinated against 2 controls watched for 12–13 rs?" The answer is, perhaps, that the trial began, years before the paper was written, as a result of ervations on largely unvaccinated children. The hors doubtless wanted to include these observations, in order to make the numbers equal they had to cinate an excess of children in the second two-year iod. The more precise standards were then laid down, in writing their report the authors overlooked the t that 12–14 years previously they had not adhered to se criteria. Professor Hill complains that in subsequent rs the groups were not always the same size; yet the areful method of allocation laid down" was: "All ldren born into the families of Group A were vaccinated one year, while all children born into families of Group in the same year were taken as controls. In the lowing year this situation would be reversed and so throughout the duration of the study." Perhaps e unfortunate investigators were not able to exert lequate statistical control over the number of children m into two groups of Red Indian families in successive ars. Yet what do these *gross* (Professor Hill's italics) ferences amount to? In the first two two-year periods ere was a large difference in the number of control vaccinated children, but this involved only 112 out of 3 children. But there is little reason to believe that the sults on these children were worthless, and Professor ill fails to mention that 73% of all the vaccinated and ntrol children lived in the same families. The remaining 7% came from families that had either all vaccinated r all control children.

He next discusses Ferguson and Simes's data on the nvironment. In the first place it should be pointed ut that even if these data are wrong they in no way ffect the validity of the trial; they are merely included to provide a background to the study. After quoting table III of Ferguson and Simes he writes:

> "These figures are said to reveal 'the infection rate among the controls using only those controls that had adequate tuberculin information.' We may waive the point (to which incidentally no attention is paid) whether these cases are a representative sample of all the controls. For the main issue is, how do the authors come at all by 157 controls observed year by year for 15 years? There is no such group in their control data—indeed only 37 have been followed for more than 12 years."

Here Professor Hill is, I think, quite right: it seemed clear to me when reading the article that these 157 children were another group altogether, whose tuberculin reactions were studied, and the information was included for general interest. It was, of course, strictly incorrect to call them "controls"; but it is really going rather far to suggest that two authors would get confused between 157 controls observed for 15 years and 37 controls observed for 12 years. It may just be mentioned that the favourable results were obtained without isolation of the vaccinated children.

It is perhaps natural that the impression left by my article should be that a controlled trial is unnecessary; but in the summary I said that "what is required is not so much an 'adequate trial' of B.C.G., as a campaign which will begin a new 'sanitary revolution' and control of the last of the great zymotic diseases in Great Britain." I think this is true, and it seems doubtful whether one is justified in carrying out a controlled trial on children or adolescents specially exposed to infection. On the other hand, everyone interested in tuberculosis will endorse Dr. Young's plea (Dec. 3) for a more intensive study of the whole subject of resistance to tuberculous infection, and there seems no doubt that an extensive controlled trial of B.C.G. should be carried out on a section of the general population—i.e., those persons not known to be exposed to special risk. During this period improved methods of producing and standardising vaccine should also be studied: the Scandinavians improved on the original methods of producing and standardising the vaccine, and I understand that important new improvements in potency, and uniformity of production, are being made in America.

As Dr. Young says, the experiments of Watson and those of Young and Paterson[4] show that the resistance of vaccinated cattle may ultimately be lower than that of controls: but the differences in the pathology of human and bovine tuberculosis[5] make it appear unlikely that one can transfer data about events in the "post-primary" stage of infection from one species to the other. Dr. Young states that "while it is true that man has a greater capacity than the lower animals for developing a lasting immunity when exposed to infection with virulent bacilli, his reactions to vaccination with an avirulent strain must be similar to those of the lower animals." I know of no evidence to support the last part of this statement, and it seems rather illogical.

The difficulty of this whole subject of active immunisation to tuberculosis can be illustrated by a quotation from Pinner and Kasper[6]:

> "Since under well-controlled experimental conditions it was shown that reinfection, frequently repeated (at different intervals), may either enhance or depress immunity, it seems hardly justified to postulate that the same mechanism should, under the more complex conditions of human life, act always one way, in other words, that repeated infections should cause the more malignant forms of tuberculosis in the Negro" (p. 487).

It is known that tuberculous infection does occur in vaccinated persons (just as reinfection occurs in persons with a "healed" primary complex) and this infection has a greater tendency to form a healed primary complex than in unvaccinated persons. Unless one assumes that it is desirable to have active tuberculosis in order to be exposed to as much antigen as possible, it seems unreasonable to believe that, under the "complex conditions of human life," the healed primary complex in a person vaccinated with B.C.G. is not as often beneficial as the healed primary complex in an unvaccinated person. At the very least it seems preferable to active disease or death. Pagel and his colleagues [7] have summarised the position admirably:

[6] Pinner, M., Kasper, J. A. *Amer. Rev. Tuberc.* 1932, 26, 463.

> "There is now ample evidence to prove that at least one reliable, safe, and sufficiently successful agent conferring partial immunity (against tuberculosis) exists. . . . It is essential to be clear as to wherein the efficacy of B.C.G. lies. Its specific value lies in the protection it confers against the risks attendant upon primary infection acquired in the ordinary uncontrolled manner. The main fall in incidence of tuberculous morbidity takes place therefore in such illnesses as are consequent upon primary infection—namely, hilar adenitis, epituberculosis, erythema nodosum, pleural effusion, tuberculous meningitis, and generalised miliary tuberculosis. As regards phthisis B.C.G. does not confer immunity directly as the vaccinated individual is merely transposed from the tuberculin-negative to the tuberculin-positive group and probably enjoys no more immunity than the person who acquired his primary infection in the ordinary way. It is possible, however, that in the case of tuberculin-negative adolescents and young adults (in whom phthisis may rapidly follow the primary infection), B.C.G., by helping to minimize the effects of the initial infection, thereby indirectly contributes towards *preventing the development of phthisis at a relatively early date*" (pp. 678 and 680).

Dr. Neville Irvine came to a similar conclusion after a detailed study of all the evidence.[8]

As Dr. Young points out, the effect on phthisis in middle or old age can be ascertained only by the large-scale use of the vaccine under controlled conditions for many years; but this does not mean that the groups of tuberculin-negative persons should be exposed to special risks of infection for many years. It may be noted that Young and Paterson [4] advocate vaccination of cattle, despite the known fact that it may sometimes lead to an eventual reduction of resistance.

Clearly there are many problems to solve before we understand all the mechanism of resistance to tuberculous infection; but no-one has questioned my conclusion [3] that the evidence supporting the value of B.C.G. is better than the evidence supporting the value of any other immunological procedure used in man. Even, therefore, if vaccination did lead to an increased susceptibility many years later (and there is very little evidence to support this view), most people might be inclined to use the vaccine, because there is a natural human tendency to postpone death and other unpleasant events for as long as possible. In any case, one hopes that with the help of B.C.G. the degree of exposure to infection will be reduced during the next 20, 30, or 40 years.

Bramhall, Cheshire. JOHN FRANCIS.

CHILDREN REFERRED TO THE PSYCHIATRIST

SIR,—May I, as a psychiatrist, put in a plea for a more balanced attitude towards those childish conditions which depend on both physical and mental factors combined in varying proportions? Nocturnal enuresis, stammer, and academic failure due to specific learning difficulty are common examples of these. And they are so often referred to the psychiatrist with the comment "I can find no physical cause. . . ." And the psychiatrist is not always without blame: "These are always psychological in origin."

Enuresis may start in over-meticulous toilet t
linked with [illegible] rsistence us
depends on [illegible] of a dec
bladder capacity. The voiding reflex acts before su
tension exists to arouse a definite sensory imp
so, in sleep, it can occur without waking the pa
Stammer often depends on confused lateral ce
dominance, which may show itself also in cr
laterality of hand and eye. School failure, in intel
children, due to backwardness in the basic sub
usually stigmatised as laziness, inattention, or la
effort, is commonly the result of crossed laterality.

Though the basis of these troubles is so often ph
by the time the child is brought for advice the con
is usually vastly complicated, and fixed, by seco
psychological disturbances in both the child an
parents. And the sufferers are often children of ne
temperament to begin with.

Treatment, to be effective, must take all these f
into consideration. A one-sided approach is s
satisfactory, and is responsible for much of the con
of thought and pessimism that surrounds these ail

HE HEALTH OF NURSES IN HOSPITAL

—The value of Dr. Court's article—and it has —will be measured by the efforts made in future rd the nurse's health.

Prophit Tuberculosis Survey showed that of the groups investigated the incidence of tuberculosis in the following descending order: (1) contacts open infection; (2) nurses in general hospitals g all classes of patients; (3) nurses in acute general tals; (4) medical students; and (5) controls. evidence in itself is a serious reflection on the ng and care of nurses. The infectious nature of the se and the means by which it is spread are known. itals are specially designed to assist in cure and have acilities to seclude infectious disease: even typhoid e nursed in a general ward. Yet, even in a teaching tal, we see the blame for infection of nurses focused e "symptomless" patients—or rather on undetected of active tuberculosis being treated for something n the general wards.

rses in training today are receiving lectures, and xpected to answer examination questions, on subjects beyond the requirements of their duties; yet rently the vital training on how to take care of selves against infection from any patient is sadly cted.

t is the doctor right in blaming the hospital? It serious matter to do so, for if the nurse is so infected, not our duty to see that she receives the very heavy pensation she might reasonably claim, as in other erous occupations? In the acute general hospital incidence of open tuberculosis among patients is umably only that of the community outside; but chances of infection of nurses outside the hospital surely much greater than in the wards, for our public eyances and public meeting houses contain a higher entration of people than the wards: such places seriously lacking in cleanliness and sanitary pretions, and the people in them are untrained and less. Further I think it might be shown that sing tends to attract young girls who have an unusual eptibility.

hough the hospital may reasonably be exonerated n blame if its cleanliness, ventilation, design, and acity are adequate, and its nurses are properly taught to avoid infection from any patient (whether known be infected or not) it cannot escape blame if it fails give the nurse proper treatment when she is found be infected. Though there is much hypocritical ration of the value of radiography in the detection of mptomless" active tuberculosis, from time to time find evidence that the serial radiographs showing e progressive disease are ignored: the nurse's record ies the entry "Still has no symptoms, and is still duty." There she remains until she goes home on liday, where her parents and the family doctor make e obvious diagnosis. The case-histories cited in the ophit report are illuminating in this respect. The ophit scholars also found that of a group of 31 nurses had definite symptoms which they had not reported. hat standard of training is that?

Nurses have the closest and longest contact of anyone the hospital with emergency patients who are usually o ill to be sent for X-ray examination, as well as with ss seriously ill patients who, unknown to the doctors, ave active pulmonary tuberculosis. It is no credit o the hospitals to admit such active cases in ignorance of their condition; and until we have better security for nurses I believe it is unjustifiable to admit, knowingly, patients with open tuberculosis to a general hospital, even for teaching purposes. It would obviously be to the patient's advantage for his doctors to know that he had active tuberculosis, for this should check rather than incite active surgical treatment. (The "simple" scraping of a localised bone focus, in one such patient, was followed within a few weeks by death from tuberculous meningitis.)

Professor Stammers states that "some would argue that these could be discovered by routine sputum tests instead of by routine radiological examinations, *but this would throw an insupportable extra burden on the laboratories*" and concludes "*the only solution to this problem* is routine X-ray examination of all admissions and *for economy* this should be with the miniature apparatus." He might not have been so dogmatic had he known more of the processes and expenses involved. He goes on to say: "And those who maintain that such a lesion should be recognised in a surgical ward solely by routine clinical examination flatter their surgical colleagues, perhaps because their own line of work no longer puts them to such a test." For myself, I would not even think of such flattery, for on the request forms for X-ray examination I usually see "routine" or "A.P. chest" and no sign at all that any clinical examination has been made. In support of the value of a sound clinical examination I may say I still find minimal radiographic evidence of tuberculosis in patients referred by general practitioners whose examinations have led them to suspect the disease. The carelessness sometimes exhibited in hospital is in contrast with this. To a request form bearing the message "X-ray chest. ? lungs touched," I was prompted—by a radiograph showing extensive tuberculosis throughout both lungs with many cavities in both—to return the full report "Not 'arf."

Birmingham. JAMES F. BRAILSFORD.

THE FUNCTION OF GASTRIC UREASE

SIR,—We have been prompted to write this letter by recent references to the composition of gastric juice [1] and to the significance of hyperchlorhydria as a possible precursor of a later ulcer dyspepsia [2] in connexion with the paper of Doll, Avery Jones, and Maclagan.[3]

The gastric juice has no constant composition apart probably from the primary acidity of the hydrochloric acid in it. In considering the pathogenesis of peptic ulcer insufficient attention has been given to the body's mechanisms for the neutralisation of acid and, above all, to the mechanisms which protect the mucosa from acid-pepsin digestion.

For this reason we feel justified in drawing attention to an important enzyme system which is present in the mucosa and can obviously act as a source of alkali both for local defence of the mucosa and for neutralisation of acid as well. This is urease, which acts in a highly specific fashion upon urea, breaking it down to ammonia and carbon dioxide. Ammonia was first recognised in the gastric juice by Bidder and Schmidt [4] as long ago as 1852, and its probable origin from the hydrolysis of urea by urease was first shown by Luck and Seth in 1925.[5] Linderstrøm-Lang and his collaborators [6] demonstrated by a histochemical technique the distribution of urease in the mucosa. It should be noted that the ferment is present in fairly high concentration in the pyloric region of the stomach, where there are no parietal cells, as well as in the fundus, and also that it is present, in much

6 Linderstrøm-Lang, K., Ohlsen, A. S. *Enzymologia*, 1936, 1, 92.

lower concentration, in the duodenum. Previous workers have speculated on the function of this enzyme, but no precise experiments have been reported.

Over the past few years we have been working on this problem and certain major conclusions have been reached :

1. Urease is always present in the gastric mucosa, though in varying concentrations depending upon the species examined. Previously this has not been generally accepted, but it is certain that from the frog up to man the stomach always contains some urea-splitting ferment. It is present in somewhat higher concentrations in the fundus than in the pylorus, but the difference between these two parts of the stomach is not so great as between the pylorus and the duodenum. The concentration of the enzyme can be increased by putting the experimental animal on a high-protein diet or by the parenteral administration of 'Urogastrone,' and by other methods.[7] In man the ferment is present in moderately high concentration—approximately the same as in the cat or dog, the two animals with the highest concentration observed. The ferment present was quite enough to neutralise large amounts of acid, and in the case of one cat could form enough ammonia to neutralise 50 ml. of $N/10$ acid per hour—far more acid than is usually secreted by that animal in this time. In man, owing to the obvious impossibility of obtaining suitable specimens, we never have been able to obtain complete quantitative studies; but, in the parts studied, the concentration of the ferment is of the same range in man as in the cat.

2. Oral administration of urea lowers gastric histamine response in both normal subjects and sufferers from peptic ulcer.[8] The percentage depression of the response is constantly greater in normal individuals and in gastric-ulcer cases than in the duodenal-ulcer subject. Recently we have, in a few subjects, administered the urea intravenously in the form of 5% solution in normal saline. The depression of the histamine response has been quite dramatic.[9]

3. Large doses of orally administered urea have been successfully used by us in a series of about 50 cases of peptic ulcer (gastric, duodenal, and anastomotic). The results have in general been satisfactory and on occasion remarkable.[9]

4. In a limited number of [illegible] peptic ulcer we have found [illegible] of urease on the very surface of the ulcer. We are obtaining successful preliminary results with a modification of Sen's[10] histochemical technique for the study of urease distribution in the mucosa. It is hoped to use this in studying suitable pathological material. Urease may be present on the ulcer surface primarily to prevent extension of the ulcer. It is too early to speculate further.

5. The achlorhydria usually found in the uræmic patient may be due to the large amounts of ammonia (as high as 50–60 mg. per 100 ml. of gastric juice) set free in the stomach. The uræmia of a gastro-intestinal hæmorrhage is often associated with improvement of the symptoms and signs of peptic ulcer; and this may, we suggest, be due to a similar response.

There is good reason to believe that urease is very important in the protection of the mucosa against acid pepsin. It may not be the only mechanism, but it is, we think, an important one. Its especially high concentration in the neighbourhood of the active oxyntic cells is far more likely to be concerned with protection of the mucosa against the nascent hydrochloric acid than with secretion of the acid itself as Glick[11] has apparently suggested. If it were important in the mechanism of acid formation, why should it be present where no acid is formed, as in the pyloric region or even the duodenum; and, above all, why should administration of its substrate, urea, greatly lower the amount of acid formed? For the neutralisation of gastric acidity this mechanism is clearly of much significance. It is interesting that the increased base produced will in turn be removed by the liver and the total acid-alkali balance remain undisturbed. Apart from such a mechanism dealing with the extra base, for each equivalent of H ions secreted an equivalent of alkali appears within the parietal cells.[12] The nat this process is discussed by Conway in a "redox" t of gastric production[13] which incorporates and e the previous organic-acid theory.[14]

The normal exposure of the gastric mucosa pepsin must be met by a normal resistance. Bre of this resistance, even in the presence of a no less than normal concentration of acid, may le gastric ulcer. It is highly probable that the exact a of a duodenal ulcer is different and depends mo excessive attack than decreased resistance.

We wish to acknowledge, with thanks, the contin received from the Medical Research Council of Irela

St. Vincent's Hospital and
University College, Dublin.

CURARE AND PRECIPITATE LABOUR

SIR,—The letter from Dr. Rollason in your i Nov. 19 raises an important issue.

It is suggested that the use of curare for an eme appendicectomy in a patient in her last mo pregnancy helped to precipitate labour and contributory factor in the birth of a stillborn The evidence adduced is by no means convincin the action of one intravenous injection of curare maintained for more than an hour and the fœtal in this case was regarded as being normal and at least 40 minutes after the injection in question. evidence suggests that fœtal distress did not aris *2–3 hours afterwards.*

It is well known that peritonitis from any cau produce a strongly acting uterus which may a to a tonic contraction, and in my *opinion* it is pr that the infective process both initiated labou produced the high tone of the uterus. I do *not* that curare by itself will produce strong contract uterine muscle, since hæmorrhage experienced cæsarean section under curare is considerably more when either a local or a spinal anæsthetic is employed

I hope that any further cases in which fœtal di might be attributed to the use of curare will be publ in order that the safety of this excellent anæsthetic *may be correctly judged.*

DEOXYCORTONE ACETATE AND ASCORBIC A IN RHEUMATOID ARTHRITIS

SIR,—The preliminary report (Nov. 26) by Lewin Wassén claiming rapid and astounding improve in rheumatic patients following the combined admini tion of deoxycortone acetate (DOCA) and ascorbic has naturally aroused great interest.

During the past year we have been studying met of measuring joint tenderness, the *power of grip,* circulation, and other physiological data which ma closely related to the rheumatic process, with a vie assessing the potency of anti-rheumatic remedies. present we have in our wards a number of pati suffering from rheumatoid arthritis in whom t factors have been followed closely over periods of sev weeks. 6 cases in whom the rheumatic condition judged to be stable were given a combined injectio DOCA and ascorbic acid as described by the Swe authors, and the results were observed closely du the following two hours and subsequently.

Of these 6 patients 1 claimed relief of pain, 2 sta that their pains were worse, and the remaining 3 no no difference. The patient who was subjectiv improved also showed a very slight decrease in jo tenderness and a slight increase in the power of g remainder there was, if anything, some increase at tenderness and some deterioration of grip but of the changes were significant. We were therefore e to observe any beneficial results from this ned injection.

nay be that Dr. Lewin and Dr. Wassén were study-atients with rheumatic fever, in whom joint dis-y notoriously varies from day to day and even hour to hour; but they do not state how long and hat manner their patients were observed before ing out this important clinical trial.

ims of this kind presented without adequate data nost unfortunate since we must all be eager to try remedy which promises to reproduce the remark-effects obtained with adrenocorticotropic hormone Cortisone' in rheumatic disease. Those of us who had the opportunity of studying the effects of one her of these substances at first hand will have little ulty in recognising similar activity in other remedies, here is a real danger that physicians without this rience may be encouraged to embark on extensive peutic trials with expensive remedies which are st certainly useless if not actually harmful.

TROPICAL POLYPHLEBITIS

R,—In recent years several reports have described cute syndrome of phlebitis and thrombosis of large s accompanied by pyrexia, observed in Northern desia,[1] Southern Rhodesia,[2] and East Africa.[3] erent names, such as primary tropical phlebitis and oathic thrombophlebitis, have been used for the lition, the cause of which is unknown.

ases observed in the Rhodesias have been sporadic ndemic, but the disease described by Manson-Bahr Charters [3] in East African troops was epidemic in acter. The circumstances led these workers to suggest possibility of a virus infection, transmitted, like ctive hepatitis, by the syringes used in venereal-ase clinics for neoarsphenamine injections. Patho-cal studies [4] indicate that the lesion in the active cute phase of the disease is essentially a replacement he media and intima by actively proliferating vascular ue, with associated polymorph infiltration and the sence of scanty but unequivocal cytoplasmic inclusion ies which can be demonstrated by Lendrum's [5] dified phloxin-tartrazine method.

ince the ætiology is unknown, it cannot be affirmed t the diseases seen in the different regions are identical. original reports, however, provide reasonable lence for the assumption that they are identical. This lso the view adopted by the authors quoted above eferring to each other's publications. They consider t the condition may be either a new disease or one ch has only lately been recognised.

he condition is probably neither a new disease nor which has only recently been recognised. For some e an apparently similar condition has been known workers in tropical medicine, though little has been tten about it. In an address to the Royal Society Tropical Medicine and Hygiene in 1930 Castellani [6] erred to polyphlebitis tropicale as a disease *sui generis* of unknown origin. He did not claim to be describing disease for the first time, but gave no previous erences.

Since the ætiology is unknown, it cannot be asserted it the condition described by Castellani is identical h that recently reported in East Africa and the Rhodesias; but his description (with illustrations) indicates that it probably is. Castellani noted that the associated œdema seems to be due to a process of periphlebitis and not to thrombosis of the vein. He emphasised the tendency to recurrence—a feature mentioned also by Manson-Bahr and Charters. Further observations on this disease by those who have the opportunity to make them are likely to be of very great interest.

REGISTRARS

SIR,—Following your leading article of Nov. 19, and the open meeting of registrars at the British Medical Association on Nov. 26 (reported in your last issue), the whole subject of registrars' prospects and conditions of service is now very much in the foreground. I attended the meeting of registrars and was struck by the small number present from the teaching hospitals and the large number from the non-teaching hospitals.

The important question arises—what is the function of a registrar? Before the war registrars were virtually unknown in the non-teaching hospitals, and in the teaching hospitals their chief function was to teach medical students. especially in the more elementary parts of the clinical course. They also helped in the outpatient department, gave general advice to house-officers, and in the surgical departments performed many of the emergency operations. By the benefit of their contact with distinguished consultants and by their own reading and experience they prepared eventually to become consultants themselves. Those that failed to make the grade—and they were not many—always had private general practice as a not very unpleasant alternative.

What, then, is the function of a registrar in a non-teaching hospital, which previously had no registrars? From discussion with colleagues who hold such posts it would appear that they act part of the time as senior house-officers and part of the time as consultants. They are often compelled to be resident the whole time. Medical registrars usually have to act as electrocardiograph technicians and often as laboratory technicians for emergency pathological work. In many cases consultants have far too many beds under their nominal care, and each consultant has one or more registrars who are doing the bulk of the work of the hospital. It is, of course, very convenient for a consultant always to have a deputy at his beck and call, but the comfort of consultants is not the only consideration. At the last meeting of members of the Royal College of Physicians (Nov. 24) I was staggered to hear consultants of non-teaching hospitals discuss the numbers (sic) of registrars each would have under his own jurisdiction. As a result of the many new registrar appointments (some still being advertised) very many men holding such posts have no chance whatever of becoming consultants.

The conclusion is inescapable. Registrars in most non-teaching hospitals are entirely redundant and all such hospitals should be staffed only by house-officers and consultants, as previously. Exceptions should only be made in the case of some large and efficient hospitals with especially able consultants on their staffs, and then the work of registrars should be recognised for what it ought to be—namely, training for consultant status.

A list of hospitals should be drawn up by each regional board or some central body, laying down clearly the hospitals in which registrars should train. This should include only the teaching hospitals (undergraduate and postgraduate), specialised hospitals, and a few—a very few—of the larger hospitals of the type mentioned above. At the same time the number and class of registrar posts should be organised so that in each grade a man

Gelfand, M. The Sick African. Cape Town, 1944.
Manson-Bahr, P. E. C., Charters, A. D. *Lancet*, 1946, ii, 333.
Fisher, A. C., Fisher, M. M., Lendrum, A. C. *J. Path. Bact.* 1947, 59, 405.
Lendrum, A. C. *Ibid*, p. 399.
Castellani, A. *Trans. R. Soc. trop. Med. Hyg.* 1930, 24, 379.

has a reasonable chance (50% or thereabouts) of obtaining a post in the next higher grade, and, in the case of the senior registrar, has about a 50% chance of becoming a consultant. Even this would only allow a junior registrar a $12^{1}/_{2}$% chance of becoming a consultant.

As far as cost is concerned, it would appear that the abolition of registrar posts and their replacement by equal numbers of full consultants and house-officers would make little difference. This, of course, would not solve the problem of many of the present holders of registrarships, and it is therefore essential, if a large number of fully trained and highly experienced doctors is not to be lost to the service as specialists, that regional boards publish as soon as possible consultant vacancies that are likely to be available in the next twelve months.

The outlook for the bulk of the present registrars, both in teaching and non-teaching hospitals, now appears very uncertain indeed; and, as was pointed out at the registrars' meeting, there are probably in no other profession so many capable men nearing middle life with so hazardous a future. If the suggestion here is adopted, at least the next generation of registrars would not be in the same position as their predecessors.

St. George's Hospital, London, S.W.1. G. P. BAKER.

SIR,—I have been reading with interest your leading article and the subsequent letters.

It is clear that many registrars are doing consultant work, and it is also obvious that the great bulk of hospital work is carried out by this class of practitioner. The Spens committee have wisely set a very high standard for full consultants with high remuneration. It will never be possible for this country to afford a large increase in this type of practitioner, even if it were desirable. The solution is to make posts of junior consultant status which carry less pay but are permanent, and from which the holders can apply for senior posts as they become available. Already one authority—Northern Ireland—is adopting this policy and many registrars would prefer this solution to wasting their training and experience.

REGISTRAR.

VITAMIN P AND ANTIBODY PRODUCTION

SIR,—In work that is to be published shortly I have suggested that what appears to be the usual pattern of plasma-protein response to infection—a lowering of the albumin/globulin ratio—is a purposive mechanism developed necessarily by natural selection, whereby the body synthesises antibody gamma-globulin in optimal relation to the lysine in the diet. This indispensable amino-acid must be obtained from the diet; for once deaminated it cannot be reaminated. Quantitatively it is the body's most important indispensable amino-acid, and plasma-albumin contains twice as much as plasma-globulin. Hence a fall in the amount needed for albumin synthesis leaves more available for globulin synthesis (the dietary intake being assumed to remain constant).

Today I came across the statement by Bicknell and Prescott [1] that in disease (presumably infections), but not in health, vitamin P decreases the serum-albumin and increases the serum-globulin. The reference given is untraceable here, but the question arises whether the increase and decrease are due in part to vitamin P or are wholly the natural response to infection. This recalls a case of kala-azar, treated in the Anglo-Egyptian Sudan in the winter of 1939–40, which much impressed me.

I was attempting to ascertain if any nutrient concentrate, given as an adjuvant with the standard antimony-tartrate treatment, would improve our results. Groups on carotenoids, carotene, thiamine, nicotinic acid, riboflavine, ascorbic acid, calciferol, and casein, as compared with controls, showed no difference. I had one bottle of vitamin P ('Hesperidin') tablets, and t there was no chance of getting any more at the time thus running a further experimental group, I ordered tablets to be given daily until finished to a fresh admitted that morning and diagnosed by splenic pun as kala-azar. The patient astonished us all by m an easy and rapid recovery, which is rarely, if e seen in Sudan kala-azar treated with antimony ta No opportunity has since been found to try vitamin as an adjuvant in the chemotherapy of infections, I others more favourably situated may be interested if inferences I have drawn from the statement of Bick and Prescott are correct.

Jiddah, Saudi Arabia. N. L. CORKILL

HÆMOLYTIC EFFECTS OF MYANESIN

SIR,—Dr. Clendon and Dr. Penfold, in their articl Nov. 26, state that "The evidence that some in vascular hæmolysis occurs after the clinical use myanesin is overwhelming."

The evidence may be strong, but it is not absolu conclusive. Our experience at the Royal Vict Infirmary, Newcastle-on-Tyne, leads me to do the occurrence of hæmoglobinuria. Pigmentation of urine—which may be red, green, or brown—has occu in a few cases. This urine gives a positive reactio the benzidine and guaiac tests, but the spectros shows that hæmoglobin is absent. The reactio apparently due to phenolic groupings, presum breakdown products of mephenesin ('Myanesin'). S one body-fluid (urine) can be red from the presenc breakdown products of mephenesin and give pos reactions to the benzidine and guaiac tests, it is impossible that similar events may occur with o body-fluids, and thus the evidence for hæmolysis g by Dr. Clendon's and Dr. Penfold's intere experiments cannot be considered overwhelming, spectroscopy was not employed.

Mephenesin is often used here in anæsthesia in chil in doses of 2 ml. of the 10% solution per stone b weight, which may be repeated if necessary. Its advan in these cases is that respiration is not markedly affe It has been employed in infants only a day old, in the poorest risks, but we have seen no adverse ch effects.

Recently, a boy, aged 13 years, with tetanus treated here with 91 g. of mephenesin in glucose-s by intravenous drip over 4 days. No sedatives employed. The effect was such that blanket baths treatment of pressure areas could be carried out wit initiating spasms. Recovery was complete and t were no untoward effects from the mephenesin.

Much adverse criticism of mephenesin has app in the literature, but unless deleterious effects ca conclusively proved it seems a pity to discourage use of a drug which can be used to obtain such exce results.

had thought that your correspondent "Ignotum lagnifico" should have remained anonymous, ld have signed myself "Lorenzo il Magnifico"! d of which I am, Sir,

ion, W.1. R. D. LAWRENCE.

ACTINOMYCOSIS

,—In your leading article last week, after describing haracteristics of *Actinomyces bovis*, you say: this reason it cannot survive on natural substrata le the animal body; so infection does not occur external sources but is always 'autogenous.'" ding to the *Shorter Oxford English Dictionary* ogenous" means "self-producing," and Dorland's *ican Illustrated Medical Dictionary* gives "self-ated; originated within the body."

iat actually is implied by the word "autogenous" ur article? The organism must come from some- and surely cannot produce itself from nothing; wise we would seem to be getting back to spon-us generation. From what does it "originate n the body" if "autogenous" is the correct word e?

eleys, Lancs. O. R. L. WILSON

* It was the infection, not the organism, that was genous—infection being "invasion of the tissues ... athogenic organisms in such a way that injury ... ts" (Dorland)—ED. L.

ACUTE MASTITIS

R,—In my letter of Oct. 22 I purposely kept my rks short; but by so doing have evidently left way open for inferences which were never intended; I have been taken to task by Mr. Hughes (Nov. 19). e agrees that it is a common farming practice to calves to suckle cows with mastitis. I said it was old-fashioned. The point was originally raised Mr. Walsh (Oct. 8) in connexion with the dangers h might arise by allowing an infant to suckle an ted breast. Mr. Walsh prefers always to boil the from the affected side; but Taylor and Way[1] did take this precaution, and—like the calf—the infants eared to take no harm. Mr. Hughes is evidently ried that one of my statements may give the impression the farming world is obtaining penicillin prepara-s through illegal channels. I simply said that the wise ner always had his tube of penicillin ointment handy eal with sores on the teats of cows.

am obliged to Mr. Hughes for drawing my attention he third point that he mentions: it is, of course, ved that, judged by penicillin content in the milk, amammary injection of penicillin is vastly superior ystemic administration. But I should perhaps have gested that this method of administration alone is able only for the less severe forms of acute mastitis e., without pronounced systemic upset. In the cow cost often precludes systemic penicillin treatment, I then content myself with sulphonamide therapy the systemic attack. At times indeed the systemic atment seems to be the more important. Generally aking, however, intramammary inoculation is always d at the same time, to provide a double safeguard. ally, I would point to Mr. Walsh's results with temic penicillin only, because in my opinion this makes it amply clear that the concentration of penicillin in the milk is not the only factor to be weighed when judging the efficacy of the various methods of treatment.

Blackburn. A. H. HOGG.

Public Health

Typhoid Fever in Salford

IN the outbreak of typhoid fever at Salford there had been up till last Monday 29 confirmed and 9 unconfirmed cases; 2 patients had died.

All the known cases became infected from meals eaten in October. The dates of the meals known to have been infected are Oct. 6, 7, 8, 27, and 28; and these dates were all before the outbreak became known and hygienic measures (including suspension from food-handling of possible carriers) were instituted. Possibly further cases may arise; there have been at least 2 ambulatory cases where subsequent relapse revealed the nature of the disease.

In all cases and carriers the *Salmonella typhi* has been of the same type—Vi-phage E.1.

Poliomyelitis

During the week ended Nov. 26, notifications in England and Wales were: poliomyelitis 176 (221), polioencephalitis 17 (8). Figures for the previous week are shown in parentheses. The number of notifications of poliomyelitis and polioencephalitis together is now a little higher than it was in the corresponding week of 1947—193 against 145. Of recent years an extension of relatively high prevalence into the winter months has been reported from other countries, and when the next review of the world situation is published by the W.H.O. it will be interesting to see how far this trend is general.

Multiple cases were reported from the following counties:

London 24 (29), Berks 3 (8), Buckingham 5 (3), Chester 6 (0), Derby 2 (1), Devon 2 (1), Dorset 3 (1), Durham 2 (2), Essex 16 (14) Gloucester 8 (8), Hereford 2 (1), Hertford 6 (4), Kent 14 (20), Lancaster 10 (10), Leicester 7 (3), Middlesex 11 (15), Norfolk 12 (3), Nottingham 5 (4), Southampton 4 (3), Stafford 3 (2), Suffolk East, 3 (2), Surrey 6 (6), Sussex, East 3 (4), Warwick 7 (13), Yorks, West Riding 17 (32), Glamorgan 5 (10).

Obituary

WILLIAM ANDERSON

O.B.E., M.B. ABERD., F.R.C.S., F.R.C.S.E.

Mr. William Anderson, surgeon to the Aberdeen Royal Infirmary, died on Nov. 29 at Aberdeen.

Born of farmer stock in the north-east of Scotland, and the eldest of a large family, William Anderson was a typical product of his race and environment. From an early age toil and sweat were familiar and almost congenial companions, and the habits of industry, application, and attention to detail, thus early acquired, became ever more deeply ingrained. In 1909 he graduated M.B. in the University of Aberdeen, and after a series of house-appointments he joined the staff of the Aberdeen Royal Infirmary as honorary anæsthetist, according to the custom of those times. In these early years he was trained by Sir Henry Gray and Sir John Marnoch, and from them he learned general surgery and much else besides.

Having taken his F.R.C.S.E. in 1912 he served during the 1914–18 war as a regimental medical officer—an experience on which he always looked back with special satisfaction—and then had charge of the surgical division of a general hospital in France. For his services he was appointed O.B.E. After the war he returned to the post of assistant surgeon at the Aberdeen Royal Infirmary, only to find promotion to a full charge blocked for many years. He made them, however, years of intensive and fruitful effort, and in 1923 he took the English surgical fellowship. In addition to work as a general surgeon in hospital and private practice, university teaching duties as lecturer in clinical surgery, and research at the Rowett Institute, he found time to initiate a neurosurgical service at Aberdeen; and later, when the need arose, he turned to thoracic surgery. The development of surgical treatment of tuberculosis at the sanatoria in the north-east of Scotland owes much to his efforts. In 1935 he became full surgeon at the Royal Infirmary, and he was also consulting surgeon to the municipal hospital group. An original member of the Society of Thoracic Surgeons, he became its president. From 1941 to 1944 he was also president of the Association of Surgeons. He was a fellow of the International Society of Surgeons.

When the late war came his services as a medical administrator were soon in demand. For a time he was surgical director in the E.M.S. for the north-east and north of Scotland, and later he became consulting surgeon, Scottish command. At the War Office, where the interests of special branches of surgery were sometimes conflicting, Brigadier Anderson's opinions were highly regarded "for their content of practical common sense, tinctured on occasion by a robust scepticism." After the war he returned to civil life with his zest for surgery and for his hobbies—shooting and golf—unimpaired. He had no thought of letting up in work or play, and he died suddenly while attending a law case as medical referee.

A colleague writes: "William Anderson, known to all in his beloved Aberdeen, and to many far beyond, as 'William' or 'Willie,' was a prominent figure in British surgical circles for a generation past. His popularity was assured by unusual gifts of easy and entertaining companionship and by an inexhaustible fund of stories. But that was only one side of the man. He was a surgeon of distinction and achievement and his career was one of which his family and colleagues might well be proud. His capacity for work was immense and it is safe to say that for years he did as much as two ordinary men and none of it slipshod. Actuated by an unswerving devotion to what he considered his duty—to his patients, to his
country, to his students—he gave of his best, reinf
always by a broad humanity, sympathy, and to
for human weakness."

J. L. adds: Anderson and I were first associated
Aberdeen, where I quickly realised that in addition
his skill in diagnosis and in operating he was a man
such simple sincerity, and so devoted to his work,
his relations with his patients were a model of what
should be. For each patient he had a different app
and the care which he took to sum up individuals and
deal with every aspect of their problems made him the
friend and wise counsellor as well as their surgeon;
always thought it a fortunate arrangement that eve
medical student in the university had the opportuni
of seeing at work so able a surgeon, who was also
superb doctor. He had the facility of shedding
unessential, whether at the bedside or in committe
and thus he was a good composer of differences
friendly chuckle, followed by his Buchan "Well, we
so often were the introduction to the outlining o
sensible and practicable course of action, into
discharge of which he almost always succeeded
drawing any who had at first disagreed with him.

During the war, when he was consulting surgeon
the Scottish command, we continued our close associa
in Edinburgh. He did his work for the Army lik
crusader—there was no trouble too great, and no d
too small, for his personal attention. He was a per
consultant: he got on well with everyone, from pri
to general: he had only one object, to do his best for
troops. In his new sphere, the absence of any pers
foible and his sound principles made him particu
welcome when the management of any condition invol
a so-called specialty was concerned. Above all, he
modest.

Those of us who loved and admired him—and
many these were—hoped that his sacrifices durin
war might be at least partly compensated for by a
and happy retirement. Instead, we must fin
epitaph: if the choice were mine it would be "W
Anderson, the good colleague."

Mr. Anderson leaves a widow and three children;
them, Dr. W. Ainslie Anderson and Dr. B. Eileen And
are graduates of medicine.

ANNA JUSTINA AUGUSTA WILSON

F.R.C.P.E., D.M.R.E.

Dr. Justina Wilson, consulting physician to
physiotherapy department of St. Mary's Hospital
on Nov. 28. Before she started her medical traini
was already a physiotherapist of standing and pri
of the Swedish Institute in the Cornwall Road.

From the Royal Free Hospital she took the Sc
triple qualification and the licence of the Soci
Apothecaries in 1916. Later she held clinical ass
ships at the Hospital for Sick Children, Great O
Street, and the National Hospital for Diseases
Heart and she was for a time in charge of the orth
department at the Miller Hospital, Greenwich. Bu
her background it was natural that she should
physical medicine as her specialty, and she was app
medical officer in charge of the electrothera
department at the Royal Free Hospital, later tak
the same position at St. Mary's Hospital. She ob
the D.M.R.E. in 1920; in 1924 she took the M.R
and four years later was elected F.R.C.P.E. Sh
an honorary member of the Chartered Soci
Physiotherapists.

F. M. S. writes: "Justina Wilson came to the
Free Hospital with the reputation of being the f
and director of a school of physiotherapy of a
hospital. She was also older than the rest of us.
two circumstances might have made it diffic
anyone else to adjust themselves to their new sur
ings. But nothing could ever daunt Justina
She was soon the most popular and the youngest
of her year and she took a leading part in every a
academic and social. We were very fond of her
admired the gay courage with which she grapple
the intricacies of a dissection and her diffic
memorising the innumerable facts presented

al student. She was never overbearing with less iced fellow students and we soon forgot that she eader in her own profession. I met her again three decades later. after she had returned to erapeutic work, and she was quite unchanged y, efficient, and always deeply concerned to do to relieve the physical disabilities of the many who sought her advice. Her passing is like the of an institution she is irreplaceable."

JOHN GRIMSHAW

M.D. LOND., D.P.H.

ohn Grimshaw was born at Fleetwood and was at the London Hospital, qualifying in 1891. everal years of general practice in Lancashire, me a civil surgeon at the Cambridge Hospital, ot, and the Herbert Hospital, Woolwich. At e he extended his particular interest and experi- ophthalmology. In 1901 he took the M.D. Lond., 1902 the D.P.H. Camb.

gh he was childless himself, one branch of public that always appealed to him was the medical ation of school-children, and in 1910 he wrote a opular guide, *The Medical Care of the School* Later he became ophthalmic surgeon to the Hospital, Liverpool, and he spent his last years ited general and ophthalmic practice in Birken- hich allowed sufficient leisure for his reading and ng.

markable knowledge of the English language was the most distinguished attribute of this gifted He loved words and had a fine taste in the choice cing of them. He was a clear thinker with high tual qualities, though his uncompromising and dent spirit kept him apart from many people evented him from reaching the position to which ity would have entitled him.

Grimshaw was proud of his profession and devoted patients and friends, who found in him a source of agement and strength; for his character was sound ong. To me he was a father in medicine, a lifelong llor, and a valued collaborator in the preparation ical contributions.

lied on Oct. 11, at the age of 82, some weeks after e, a companion of charming personality.

JOHN PARKINSON.

FRANK THORNTON BIRKINSHAW

M.R.C.S., L.M.S.S.A.

F. T. Birkinshaw, who died at his home in Auckland, ealand, on Oct. 2, was born at Ovingham-on-Tyne 9. From King Edward VI School, Birmingham, nt to the university in that city. In the first war he joined the Royal Warwickshire Regiment was later attached to the Royal Air Force, in he served with a special duty flight attached to edjaz army. For a time he was the personal pilot E. Lawrence, and he was decorated by the French ritish Governments.

1925 he qualified from University College Hospital, e years later he emigrated to New Zealand where actised in Amberley and Christchurch. In 1937 urned to this country for postgraduate study and in a London County Council hospital for eighteen . In 1943 he was appointed superintendent of oromandel Hospital in Christchurch. He gave up post in 1943 to settle in consultant practice in land, where he was also active as a producer in atic circles.

Birkinshaw is survived by his wife, Dr. Edna nshaw, and by a son and daughter.

Appointments

G. E., M.B. Lpool, D.M.R., D.M.R.E.: consultant radiologist, King's Lynn area.

A. A., M.B. St. And., F.R.C.S.E.: consultant ear, nose, and throat surgeon, Peterborough area.

G. S., M.B. St. And.: M.O., Uganda.

Major F., M.B., B.S., D.P.M., barrister-at-law; deputy medical superintendent, Cell Barnes Colony.

* Amended notice.

Notes and News

SMOKE

SPEAKING in London on Nov. 30, Sir George Elliston said that a report recently issued by the Federal Health Authority in Washington on last winter's fatal smoke fog in Donora,[1] when over 20 people died and 40% of the population were made ill, showed that the chief culprit was sulphur dioxide, the corrosive constituent of London fogs. "About the same time, here in London, a week of fog sent up deaths by 20–30% over the average for the previous four weeks, while the number of deaths from bronchitis were more than doubled. . . . It is perfectly certain that if we have a spell that is both dense and persistent, such a rise in mortality will again recur." Two and a half million tons of unburned coal particles are poured each year into the atmosphere, in the form of smoke; and under the conditions of faulty combustion that give rise to smoke there are heat-losses four or five times greater than this in the form of burnable gases—actually crude coal gas—so that altogether the equivalent of 10 million tons of coal or more are wasted yearly as, and with, smoke. "In other words, 2½ weeks' output of the mines each year goes—though it does not vanish!—into thin air." Happily, he continued, the remedies are identical with the programme for using fuel-supplies more efficiently and for improvements in the warming of houses. Even now a revolution is in progress—"a slow, hardly noticeable, and typically British revolution"—so that in fifty years or less the old-fashioned coal fire will be as obsolete as is the open sewer today. Sir George commended the abolition of smoke by stages through the setting up of expanding smokeless zones as preferable to any of the more spectacular methods that might be envisaged.

University of Cambridge

On Nov. 26 the degree of M.D. was conferred on Philip Hugh-Jones.

At a congregation held on Dec. 3 the proposals of the General Board on the new scale of stipends for university teaching officers were approved by 315 votes to 47. Three scales of emoluments are proposed for clinical, preclinical, and non-medical posts. (See *Lancet*, Nov. 19, p. 970.)

Royal College of Physicians of London

On Jan. 10 and 12 Dr. Howard Nicholson will give the Goulstonian lectures on Suppurative Pneumonia. On March 14 and 16 Dr. E. E. Pochin will give the Oliver-Sharpey lectures on the Investigation of Thyroid Function and Disease by the Use of Radioactive Iodine. All the lectures will be held at 5 P.M. in the college, Pall Mall East, S.W.1.

Royal College of Physicians of Ireland

On Dec. 2 the following, who have passed the final examination of the Conjoint Board in Ireland, were admitted to the licentiateship of the college:

Eugene Bradley, P. G. Brady, H. D. Coghlan, Jane J. Connolly, L. A. Cullen, J. C. Dillon, J. A. Doherty, Rita D. Dooley, Elizabeth M. Farrell, J. A. Fitzpatrick, J. B. Gallagher, Rhoda P. Kennedy, M. J. Moran, J. E. Murphy, J. R. Murphy, J. A. McCarthy, Eva T. McDonald, J. F. McGuire, O. A. McKee, Mary T. McQuaid, J. F. Napier, D. O. Ndukwe, Maeve S. O'Kelly, C. M. Ongley, William Quirke, B. F. Regan, Irving Rosenthal, Catherine T. Tynan, Mary T. Vass, A. M. Wells.

Royal College of Surgeons in Ireland

On Dec. 2 the following were admitted to the fellowship: W. G. Fegan, J. H. Johnston, W. R. Lamb.

Royal Society

Prof. E. D. Adrian, O.M., has been elected foreign secretary of the society, and Prof. G. L. Brown, Dr. F. M. R. Walshe, Dr. V. B. Wigglesworth, and Prof. S. Zuckerman members of council.

Scientific Films Census

The information service of the Scientific Film Association is making a national survey of makers, owners, and users of scientific films. Information has been collected already from over 400 film-makers and distributing agencies, but it is believed that there are many more whose names and films are known only to a limited number of people. Details should be sent to the secretary, at 4, Great Russell Street, London, W.C.1.

---

[1] See *Lancet*, 1948, ii, 738.

Society for the Study of Addiction

Dr. Erik Jacobsen (Copenhagen) will speak at a meeting of this society on Tuesday, Jan. 10, at 8 P.M., at 1, Wimpole Street, London, W.1, on Biochemical Methods in the Treatment of Alcoholism with special reference to 'Antabuse.'

Oxford Graduates Medical Club

The 100th dinner of this club will be held at the Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2, at 7.30 P.M. on Friday, Jan. 27, when Dr. C. M. Hinds Howell will take the chair. Tickets (price 26s.) may be had from Mr. E. G. Tuckwell, 73, Harley Street, W.1, before Jan. 13.

Plan for W.H.O. Headquarters

The World Health Organisation building committee has tentatively approved a plan by which the organisation will establish its headquarters in the Palais des Nations at Geneva, under a 99-year lease. The plan provides for additional construction at a cost of 3,684,000 Swiss francs; and the offer by the Swiss government of a grant of 3,000,000 francs has been accepted.

Congress of Obstetrics in the U.S.A.

The international and fourth American Congress on Obstetrics and Gynæcology will be held at Hotel Statler, New York, from May 14 to 19, 1950. The English speakers will include Prof. H. L. Sheehan, who will read a paper on the Kidney in Abruptio Placentæ. Further particulars may be had from Dr. Fred L. Adair at 161, East Erie Street, Chicago, 11, Ill.

Claims to Sickness Benefit

In England and Wales new claims to sickness benefit under the National Insurance Act during each of the four weeks ended Nov. 1, 8, 15, and 22 were as follows: 121,900, 135,000, 142,300, and 136,800. These figures are given in the Registrar-General's return for the week ended Nov. 26, which also records the weekly averages for new claims in each month from January to October of this year. These are as follows: 157,800, 180,100, 185,400, 114,400, 97,900, 83,700, 78,500, 88,900, 100,900, and 119,200.

No Health Centre for the Festival

The London County Council's public-health committee has informed the council that it has proved impossible to proceed with the building of the comprehensive health centre which was to have formed part of the "live architecture" exhibition in the Stepney-Poplar reconstruction area for the 1951 Festival of Britain. The Minister of Health was willing to approve the construction of a simple building to accommodate a small group practice; but this suggestion was unacceptable to the committee, and the site is to be reserved until a comprehensive centre can be built.

Anti-histamine Drugs as Cold Cures

The American Medical Association is reported by B.U.P. to have issued a warning against the indiscriminate use of anti-histamine drugs for the prevention and treatment of colds. The association's council on pharmacy and chemistry says that "experience with these drugs is not yet long enough to know whether or not they are harmless when used over long periods of time. Furthermore, the amounts taken during persistent colds may definitely be beyond what has been established as safe." The council is reported as stating that records show that about one-third of those who take these drugs become drowsy or even fall asleep while at work or occasionally even when driving a car.

Nuffield Grants for Research on Cortisone

The Nuffield Foundation have given the University of Oxford a grant of £10,000, payable over three years, for research, to be carried out under the direction of Sir Robert Robinson, P.R.S., into the synthesis of 'Cortisone' and analogous substances.

The foundation have also made a grant to the University of Cambridge of £5000 over three years for work, under Prof. A. R. Todd, F.R.S., on the convenient synthesis of peptides and their application in particular to the adrenocorticotropic hormone problem and on the synthesis of compounds with cortisone activity but simplified structure. A second grant, of £11,000, will be spent on work, under Prof. F. G. Young, F.R.S., on pituitary adrenocorticotropic hormones.

IC ULCER CASES REVIEWED AFTER TEN YEARS

T OF MEDICAL TREATMENT AND INDICATIONS FOR GASTRECTOMY

URENCE MARTIN
D. Camb., F.R.C.P.
PHYSICIAN

NINIAN LEWIS
M.B. Lond.
MEDICAL REGISTRAR

ADDENBROOKE'S HOSPITAL, CAMBRIDGE

OUGH peptic ulceration is one of the commonest porary diseases, the prognosis at the onset of any ual case is uncertain and the response to medical ent or the need for eventual surgery is unpre- e. The very nature of the disease is a major e to acquiring knowledge of these fundamental . For peptic ulceration, while frequently chronic, ecessarily incapacitating, and hospital treatment e dictated only by the appearance of a major ation.

reatment is common and medical advice may or never be sought. Thus when hospital treatment itial the cases are usually severe or complicated, ild or early ones are seldom admitted. After ion responsibility for the patient is inevitably l between the physician, surgeon, and radiologist, ch contributes his own limited services according umstances. Thus it is exceptional for all those ned with a case to have a comprehensive vista whole course. This fact is reflected in the vast ecialised literature, which tends to divide rather unify our knowledge of peptic ulceration. Papers pically concerned with statistics of incidence. experiments, X-ray findings, surgical techniques hort-term results. the vaunting of ephemeral l cures, and treatments for hæmorrhage. We een unable to discover any series of cases in this y which provides a follow-up survey of ten years, ry few from elsewhere.

sort to surgery for peptic ulceration is generally ed as a failure of medical measures; but the n as to whether medical treatment can in fact ce the natural course of the disease has scarcely considered. It must be admitted that orthodox ent by milk diet and alkalis, and even unorthodox ies, will usually relieve the pain of a relapse. his is not synonymous with healing of the ulcer guarantee against future trouble even though the ent is continued indefinitely. Moreover, the gical healing of an ulcer is still a questionable of the effectiveness of any medical treatment, for nown to take place under the simple influence of admission to hospital. We believe that the only of assessing the worth of any treatment in a fre- ly chronic disease like peptic ulceration is by a long- follow-up survey which will show whether or not atural course has been influenced for the better. sessment of the effectiveness of prolonged medical nt for peptic ulceration is an important matter that one of its main props—the hazard of gastric y—is being steadily knocked away by skilled hands. over, it is becoming more and not less difficult ur present social and economic circumstances for patients to attain such dietary ideals and mental quillity as are said to promote quiescence. Finally, pathetic gratitude of patients at long last relieved by ry emphasises the burden of human misery which have to be borne during the prolonged medical ment of a chronic peptic ulcer.

PRESENT SURVEY

e have followed up, in 1948 and 1949, all the loubted cases of peptic ulceration which were admitted to the medical and surgical wards of Addenbrooke's Hospital during the five years 1934–38 inclusive. There is thus a minimum follow-up period of ten years, and the results should be representative of those from any moderate-sized provincial hospital. Apart from essential surgery dictated by perforation, the majority of patients were treated medically, and the material is thus suitable for the assessment of medical treatment as the prime object.

The criteria adopted for the inclusion of a case in the series were either the unequivocal radiological demonstration of an ulcer crater or its verification at operation or necropsy. There are thus no doubtful cases. These criteria, however, must necessarily have excluded some cases of hæmorrhage from ulcers which had healed by the time that a barium meal could safely be given, and others—particularly duodenal—in which scarring or local tenderness was only presumptive radiological evidence of ulceration.

SURVEY METHODS

A total of 195 cases were traced (vide infra) and the great majority were interviewed and examined at hospital or at their homes. When this was impossible a postal questionnaire was submitted. It was neither necessary nor desirable to submit all cases who attended the hospital to a barium-meal examination, but this was carried out if possible on all cases of doubtful activity and on some which were evidently active and in need of treatment. Thus those which were clinically inactive were not X-rayed and the whole assessment of activity or otherwise was essentially clinical.

Criteria of Activity or Inactivity

A history of characteristic ulcer dyspepsia during the five years before follow-up was held to constitute activity, and the absence of such symptoms was accepted as inactivity. We avoided the word "cure" because experience shows that an ulcer may sometimes recur, or a new one appear, after a longer interval than five years.

Regimen Before Follow-up

Patients were questioned in detail as to whether they had or had not adhered to a regular regimen of alkaline powder and diet since discharge from hospital in 1934–38. As a result, we were able to classify them into three groups—regular regimen, occasional regimen, and none. These details were not available for the patients who were dead or untraced: but, in the former, we knew in many instances whether their ulcers were active at the time of death.

Material

The hospital records for the five-year period of 1934–38 showed a total of 356 inpatient cases of peptic ulcer which fulfilled our criteria. Of these 337 (94·7%) were accounted for as shown in table I.

TABLE I—THE MATERIAL

Type of ulcer	Dead	Traced	Untraced	Total
Gastric	97	123	11	231
Duodenal	35	62	8	105
Gastric — duodenal	10	10	..	20
Total ..	142	195	19	356

In the gastric — duodenal cases the ulcers had been simultaneous or consecutive. Cases of anastomotic ulcer are included under the heading of the primary ulcer.

The *sex ratios* are shown in table II.

TABLE II—SEX RATIOS

Type of ulcer	*Males*	*Females*	*Ratio M : F*
Gastric	178	53	3·4 : 1
Duodenal	92	13	7 : 1
Gastric + duodenal	18	2	9·0 : 1
Total ..	288	68	4·2 : 1

CASES KNOWN TO BE DEAD

Of the 356 cases 142 were known to be dead (table I): 75 died as a direct result of their ulcers (table III), 61 from other causes (table IV), and 6 cases of gastric ulcer from carcinoma of the stomach. For these last the diagnosis was confirmed by necropsy in only 2 and we have no evidence that carcinoma arose from the ulcers previously known to be present.

If we take the 75 patients who died as a direct result of peptic ulcer and the 23 who died from other causes but with active ulcers, we may say that at least 98 (27·5%) of the 356 in the series died with active peptic ulceration within the follow-up period of ten to fourteen years. This figure might be slightly higher if 19 cases had not been untraced.

UNTRACED CASES

In all, 11 gastric and 8 duodenal cases were untraced (8% of the series). Of these, 3 are known to be alive, but some, in view of calculated present ages, are probably dead.

TRACED CASES: *ASSESSMENT OF MEDICAL TREATMENT*

At follow-up there were 123 gastric and 62 duodenal cases who were traced or examined. They had undergone various treatments either while in hospital in 1934–38, before, or afterwards, and were classified as active or inactive (table V) according to whether there was a history of characteristic ulcer dyspepsia during the five years preceding our inquiry. Of the 123 gastric cases 50% were active and 50% inactive (62 and 61 cases); of the 62 duodenal cases 38 (61%) were active, and 24 (39%) inactive.

TABLE III—DEATHS AS DIRECT RESULT OF ULCER

Cause	Gastric	Duodenal	Gastric + duodenal	Total

Perforation + operation ..	21	7	2	30
Perforation. No operation	5	2	..	7
After gastrectomy.. ..	6	1	2	9
After gastro-enterostomy..	3	3	..	6
After other operations for ulcer	5	2	1	8
Total	49	20	6	75

For the assessment of medical treatment it was considered fair to include patients who had undergone the simple repair of a perforation, but those who had been subjected to gastro-enterostomy and gastrectomy were excluded. Thus 96 gastric and 43 duodenal cases were available for the assessment of medical treatment and were subdivided according to the dietary regimen which they had followed since 1934–38 (table VI).

This table shows that 42 (44%) of 96 gastric cases and 14 (32·5%) of 43 duodenal cases were inactive at follow-up. It also shows that perseverance with a regular regimen of diet and alkalis by 39% of active gastric and 65·5% of active duodenal cases, and an occasional regimen by 54% of active gastric and 31% of active duodenal had not caused healing of the ulcers. Conversely, *abandonment of treatment* by 55% of inactive and 57% of inactive duodenal cases had not adv affected the progress of healing of the ulcers. results suggest that the continued activity of gastric and duodenal ulcers favoured perseverance the ulcer regimen and that inactivity encouraged aba ment of treatment. This is only human nature or co sense on the part of the patients. Thus we may s that the natural course of the ulcer towards healing chronicity determined perseverance or otherwise treatment and not vice versa.

Subsequent Hæmorrhage and Perforation

To test this hypothesis further we examined effect of regimen upon the occurrence of subseq hæmorrhages and perforations after the patients hospital in 1934–38.

TABLE IV—DEATHS FROM OTHER CAUSES

Type of ulcer	Ulcer active	Ulcer inactive	Activity unknown
Gastric	16	9	17
Duodenal	6	1	8
Gastric + duodenal ..	1	..	3
Total	23	10	28

Taking the active and inactive gastric, and the a and inactive duodenal cases together, we found 13 (14%) of the 96 gastric cases and 11 (25%) of t duodenal cases had sustained subsequent *hæmorr* Of the 13 gastric cases 5 had followed a regular reg and 8 had occasional treatment, and of the 11 duo cases 9 had taken a regular regimen, 1 had occas treatment, and 1 had none. Thus hæmorrhage place in only 1 of those who had abandoned treat Only 2 gastric and 2 duodenal cases perforated, of 1 had taken regular treatment, 2 occasional treat and 1 no treatment.

We cannot say what would have happened if no the cases had taken diet or powder, but it is notew that only 1 hæmorrhage and 1 perforation took among those who had abandoned it. The facts su again that the natural course of the disease was influenced by medical treatment. Those cases which active persevered with their regimen and also suff complications, while those who were inactive aband treatment and had no trouble.

Effect of Length of History on Follow-up Results

It is a matter of common observation that peptic ulcers heal quickly without relapse, some sh tendency to heal over a period of several years, others pursue a relentless course to chronicity. W course will be followed by any one case cannot be pred

TABLE V—RESULTS AT FOLLOW-UP

Treatment	Gastric active	Gastric inactive	Total gastric	Duodenal active	Duodenal inactive
Medical ..	16	30	76	24	12
Medical + suture of perforation ..	8	12	20	5	2

Total	62 (50%)	61 (50%)	123	38 (61%)	24 (39%)

onset and can only be recognised in retrospect. ong-term survey, therefore, it is possible to detect results the influence of ulcers which have different s. Thus, if we classify the cases which were tively active and inactive at follow-up into groups ling to the length of their histories before hospital nent in 1934–38, we find a significantly higher rtion of those with a short history in the inactive (table VII). This finding was also noted by g et al. (1943), Qvigstad and Römcke (1946), almros and Hiertonn (1949).

us for the gastric cases there was a quite significantly greater chance of cases clearing up and being ve ten years later if they had a short rather than g history at the time of admission to hospital in -38. The difference is not so marked in the duodenal but the trend is the same and supports the g for gastric cases.

at this effect was not due to a greater effect of al treatment in cases with a short history is shown le VIII which sets out the regimen followed by active nactive gastric and duodenal cases with long or short ries on admission to hospital in 1934–38.

ble VIII shows the same state of affairs both for ic and duodenal cases. Almost all the cases which active at follow-up had had regular or occasional ment irrespective of the length of their history 1934–38. Conversely about half the number of ive cases, irrespective of length of history, had doned treatment. There is thus additional support ur belief that the natural course of the peptic ulcer the main factor which influenced perseverance or wise with treatment, as well as the patient's state llow-up.

ic + *Duodenal Ulcer Cases*

the 20 gastric + duodenal ulcer cases 10 were dead es III and IV). The remaining 10 cases are too few complicated to allow of detailed analysis, but the ts of medical treatment with or without simple re of a perforation showed the same characteristics he results in cases with gastric or duodenal ulcer e.

TABLE VI—MEDICAL TREATMENT

State at follow-up	Regular regimen	Occasional regimen	None	Total
ic active ..	21 (*39%*)	29 (*54%*)	4 (*7%*)	54
enal active ..	19 (*65·5%*)	9 (*31%*)	1 (*3%*)	29

enal inactive..	5 (*36%*)	1 (*7%*)	8 (*57%*)	14

f 6 cases treated medically (3 of gastro-enterostomy 1 of gastrectomy being excluded) 5 were active at w-up in 4 of which a regular regimen had been wed. The remaining case had become inactive treatment had been abandoned.

clusions Regarding Medical Treatment

n view of the fact that medical treatment only gave the earance of successful results in 42 (44%) of 96 gastric in 14 (32·5%) of 43 duodenal ulcers at follow-up er ten years (table v) we agree with Heuer (1944) t it is unlikely to be successful in more than 50% cases which have to be admitted to hospital. One his main criticisms of it was that it continued too long ore surgical aid was sought; for, like others, he found t the longer medically treated cases are followed the r-e the results become. Thus Natvig et al. (1943), a three-year follow-up of 152 gastric and 230 duodenal er cases treated medically, found that 44% and % respectively were free from symptoms; but when Qvigstad and Römcke (1946) reviewed the same cases again after $6^1/_2$–$9^1/_2$ years only 22% of gastric and 10% of duodenal cases were symptom-free. Similarly Malmros and Hiertonn (1949) recorded successful results from three weeks' medical treatment in 93·5% of 687 peptic ulcer cases; but when the same patients were followed up after 7–10 years only 36·5% of 192 gastric and 29% of 495 duodenal cases showed favourable results, and not all of these were entirely free from ulcer dyspepsia.

TABLE VII—ACTIVITY AT FOLLOW-UP IN RELATION TO LENGTH OF HISTORY BEFORE ADMISSION TO HOSPITAL IN 1934–38

Type of ulcer	Length of history before admission	Active	Inactive	Total
Gastric	2 years or less ..	19	26	45
	More than 2 years ..	35	16	51
	Total.. ..	54	42	96
Duodenal	2 years or less ..	10	7	17
	More than 2 years ..	19	7	26
	Total	29	14	43

For gastric cases, χ^2 exceeds 5 after adjustment for continuity.

From all this evidence and our own results we might well use the same words as Malmros and Hiertonn (1949): "To be perfectly honest the post-investigation presented here is a proof that medicinal ulcer therapy in the accepted form has resulted in almost complete failure." Yet it is remarkable, as we have commented, that the very ability of medical treatment to stay the progress of an ulcer does not seem to have been previously questioned. The reason surely must be that short-term results have been too readily accepted—probably for fear of surgery—and that cases have not been reviewed after a sufficiently long interval. It is undeniable that medical treatment relieves the discomfort of most relapses; but, from our present evidence we cannot believe that it is any protection against further trouble if this is destined by the ulcer.

CRITERIA FOR GASTRECTOMY

We have concluded that medical treatment did not influence the natural course of peptic ulcers in this series, and we now suggest that gastrectomy should be employed in chronic cases more often and earlier. We do not specify gastrectomy as an ideal or infallible cure for chronic peptic ulceration, and for some cases gastro-enterostomy is still the operation of choice. But, with the waning of enthusiasm for vagotomy in duodenal ulcer, gastrectomy remains our best alternative to medical treatment.

TABLE VIII—ACTIVITY AT FOLLOW-UP IN RELATION TO LENGTH OF HISTORY BEFORE ADMISSION TO HOSPITAL IN 1934–38 AND TO REGIMEN AFTER DISCHARGE

Type of ulcer	Length of history before admission	Regular or occasional regimen	No treatment
Gastric	*2 years or less:*		
	Active (19) .. .	95%	5%
	Inactive (26)	42%	58%
	More than 2 years:		
	Active (35)	92%	8%
	Inactive (16)	50%	50%
Duodenal	*2 years or less:*		
	Active (10)	100%	0%
	Inactive (7)	43%	57%
	More than 2 years:		
	Active (19)	95%	5%
	Inactive (7)	43%	57%

TABLE IX—DURATION OF ACTIVITY AT FOLLOW-UP

Duration of activity (yr.)	Gastric active		Gastric inactive		Duodenal active		Duodenal inactive	
1–5	0		15	(55%)	0		2	(50%)
6–9	0		8		0		5	
10–15	23	(42·3%)	13	(31%)	12	(41%)	2	(14%)
16–25	26	(57·5%)	2	(14%)	10	(59%)	3	(36%)
26–30	3		2		3		2	
30 +	2		2		4		0	
Total	54		42		29		14	

It should be recalled that cases were classed as active at follow-up if they had symptoms then or within the previous five years; thus the estimated duration of activity may be slightly too long in some as, for instance, in those whose symptoms had ceased four years previously. Conversely, those classed as inactive had *no symptoms* during the previous five years, and their duration of activity was accurately determined.

The generally accepted indications for gastrectomy are intractable chronicity of an ulcer with or without complications, the risks of further hæmorrhage or perforation, the hazard of malignant change, and as an emergency measure to arrest continuing hæmorrhage. From our present series we cannot comment upon the risk of malignancy beyond noting that 6 (3%) of the 231 gastric cases have so far died from it. Nor have we any cases in which gastrectomy was used to arrest hæmorrhage. Therefore, in suggesting more frequent and earlier gastrectomy, we put forward evidence from this series to show when an ulcer may be finally regarded as chronic, and what were the risks associated with hæmorrhage and perforation in relation to the age of the patient and the duration of ulceration.

CRITERIA OF CHRONICITY

As already stated, a peptic ulcer may either heal within a few years without relapse—even after an initial hæmorrhage or perforation—or it may heal more slowly over a period of several years, or steadily become chronic. Because the course which an ulcer will take cannot be predicted at the onset our problem is to determine how soon chronicity may be assumed and the question of gastrectomy be considered. It is as important not to advise gastrectomy for an ulcer which may still heal as it is to advise gastrectomy when chronicity is established. In table IX we show the calculated duration of activity of all the medically treated cases of gastric and duodenal ulcer which were available for follow-up (96 gastric and 43 duodenal, as in table VI). Cases treated by elective surgery are excluded because their duration of activity had been artificially terminated, and also the cases which were dead or untraced, because the exact duration of activity was unknown in many.

TABLE X—DURATION OF ACTIVITY IN GASTRIC AND DUODENAL CASES

Duration of activity	% of gastric (active + inactive) (96)	% of duodenal (active + inactive) (13)
Less than 10 years	24	16
10–15 years	37·5	33
More than 15 years.. ..	38·5	51

Thus no active gastric or duodenal cases had, at follow-up, a duration of activity of less than five or ten years; whereas 55% of the inactive gastric and 50% of inactive duodenal cases fell into these groups. At the other end of the scale the opposite conditions were observed, in that 57·5% of active gastric and 59% of active duodenal cases had a duration of activity exceeding fifteen years, as compared with 14% of inactive gastric and 36% of inactive duodenal cases. Intermediate between the two, with a duration of ten to fifteen years, were 42·5% of active gastric, 41% of duodenal, 31% of inactive gastric, and 14% of duodenal cases.

The analysis thus provides evidence of the three of peptic ulcer with different courses, together arbitrary standards for their retrospective according to duration of activity. It is that there is no significant difference in the prop of the three types in the gastric and duodenal when active and inactive cases are taken (table X).

We may thus suggest that a peptic ulcer which inactive within five or ten years will probably so, but if activity is prolonged to fifteen years the are 2 or 3 to 1 against healing, and beyond fifteen an ulcer almost certainly will not heal. We therefore, that gastrectomy ought to be all peptic ulcers of ten years' duration, from point onwards the chances of healing rapidly diminish

THE RISKS OF HÆMORRHAGE

By hæmorrhage we mean a melæna or hæmatem which was sufficient to alarm the patient or necess admission to hospital. Table XI summarises the m statistics, which do not differ significantly for all gas and duodenal cases in the series.

TABLE XI—*HÆMORRHAGE*

—	Gastric cases (231)	Duoden cases (10
Cases of hæmorrhage	62 (*26·8%*)	37 (35 3
Cases which bled more than once..	15 (*6·4%*)	11 (*10 4*
Deaths from hæmorrhage	9 (*3·89%*)	5 (4 7%
Chance of bleeding	1 in 3·7	1 in 2
Chance of bleeding more than once	*1 in 15·4*	1 in 9 5
Chance of death from hæmorrhage	1 in 25·6	1 in 21

The mortality from hæmorrhage among those bled was 14·5% for gastric and 13·5% for duode cases. Curiously enough only *1* of 26 patients bled more than once died of hæmorrhage—a duode case from the fourth hæmorrhage after 24 years' activ The incidence of hæmorrhage in this series agrees the estimate of 30% for all gastric and duodenal ul made by Hurst and Ryle (1937).

Hæmorrhage in Relation to Age

Table XII shows in groups the ages of 62 gastric 37 duodenal cases who bled; 26 cases bled more once and their ages at the last hæmorrhage have taken.

Thus the great majority of hæmorrhages (83·5% gastric and 81% of duodenal) took place between ages of forty and seventy, with approximately eq frequency in each of the three decades. The incide rose with age to a *maximum* about fifty years,

TABLE XII—HÆMORRHAGE IN RELATION TO AGE

Age at hæmorrhage (yr.)	Gastric cases (62)		Duodenal cases (37)		Gastric deaths (9)	Du den deat (5
20–29	1 (*1·5%*)		1 (*3%*)		0	0
30–39	6 (*10%*)		5 (*13%*)		0	1
40–49	15 (*24%*)	*83·5%*	10 (*27%*)	*81%*	0	1
50–59	21 (*34%*)		9 (*24%*)		4	0
60–69	16 (*25·5%*)		11 (*30%*)		4	3
70–79	3 (*5%*)		1 (*3%*)		1	0

E XIII—HÆMORRHAGE IN RELATION TO DURATION OF ULCERATION

	Gastric cases (62)	Duodenal cases (37)	Gastric deaths (9)	Duodenal deaths (5)
	20 (*32%*)	12 (*32·5%*)	3	2
	7 (*11·5%*)	3 (*8%*)	2	0
	35 (*56·5%*)	22 (*59·5%*)	4	3

ed by Lewin and Truelove (1949) and Avery (1947) in large series of cases. The 9 gastric ts who died of hæmorrhage were all over fifty of age and of the 5 fatal duodenal cases 2 were fifty and 3 over sixty, thus showing the well-ised predominance of mortality in elderly patients.

rrhage in Relation to Duration of Ulceration

able XIII the cases of gastric and duodenal hæmor-are arranged according to the times after onset eration at which bleeding took place. As before ve taken the last hæmorrhage for those who bled l times.

s table shows clearly that nearly 60% of both c and duodenal hæmorrhages took place after ten activity or more with a similar proportion of the s. It also shows a not inconsiderable incidence) of hæmorrhage, and deaths from it, in gastric and nal cases within five years of onset.

may summarise the situation regarding ulcer rrhage in this series by saying that the chance of rrhage was about 1 in 3 for all gastric and duodenal and the chance of dying from it was 1 in 20 to 25. bleeding took place it did so in 80–85% of cases en the ages of forty and seventy with equal fre-y in the three decades, and in about 60% of cases ten years or more of activity. The mortality was ntrated in the patients over fifty.

THE RISKS OF PERFORATION

ble XIV shows the main statistics for perforation of ic and duodenal ulcers.

e mortality from perforation among those who ined it was 33% for gastric and 43·5% for duodenal

TABLE XIV—PERFORATION

	Gastric cases (231)	Duodenal cases (105)
of perforation	78 (*34%*)	23 (*22%*)
who perforated twice	7 (*3%*)	1 (*1%*)
s from perforation	26 (*11%*)	10 (*9 5%*)
e of perforation..	1 in 3	1 in 4
e of death from perforation ..	1 in 9	1 in 10·5

. Since 5 gastric and 2 duodenal cases died without tions and 7 gastric and 1 duodenal case perforated , the operative mortality after perforation was 26% astric and 36% for duodenal cases. Having regard e respective numbers of perforations and totals of , we can say that there is no significant difference he statistics for gastric and duodenal perforation. perhaps of interest to note that whereas the chance erforation of an ulcer was about the same as that for morrhage, the chance of dying from perforation was e as great (tables XII and XIV).

foration in Relation to Age

n table XV the cases of gastric and duodenal perfora-n are arranged in age-groups; the age at the second foration has been taken for those who perforated ice.

This shows some difference between the relation of age to the occurrence of perforation in gastric and duodenal ulcers. In gastric cases the frequency was similar to that of hæmorrhage—namely, an increase with age so that 80% of perforations took place between the ages of forty and seventy with a maximum incidence (36%) in the sixth decade. In duodenal cases, however, the incidence was spread more evenly over the age-period of thirty to seventy years with maximum values (26·5%) in the fourth and seventh decades. Nevertheless 60·5% of perforations took place between the ages of forty and seventy.

Perforation in Relation to Duration of Ulceration

Table XVI shows the times after onset of ulceration at which perforations took place; in those who perforated twice the time of the second is taken.

This table shows clearly an equal incidence (about 45–50%) of perforations within five years of onset or after ten years both for gastric and duodenal cases. 11 of 26 gastric and 5 of 10 duodenal deaths from perforation took place in cases with ten or more years' activity; but 14 gastric and 5 duodenal deaths also took place within five years of onset, a finding partially due to perforation of acute ulcers.

TABLE XV—PERFORATION IN RELATION TO AGE

Ages at perforation (yr.)	Gastric cases (78)		Duodenal cases (23)		Gastric deaths (26)	Duodenal deaths (10)
20–29	5 (*6%*)		2 (9%)		0	1
30–39	7 (*9%*)		6 (*26·5%*)		1	3
40–49	13 (*17%*)	*80%*	4 (*17%*)	*60%*	0	1
50–59	28 (*36%*)		4 (*17%*)		11	1
60–69	21 (*27%*)		6 (*26·5%*)		13	3
70–79	4 (*5%*)		1 (*4%*)		1	1

We may conclude, then, that with a 1 in 3 chance of perforation for all gastric and duodenal cases (table XIV) it was equally likely to take place within five years of onset or after ten years, with only a small incidence in the intervening years. The age-incidence differed somewhat for gastric and duodenal cases in that 80% of gastric perforations occurred between the ages of forty and seventy years as compared with 60·5% of duodenal perforations. This suggests that duodenal ulcers tend to perforate earlier in life than gastric ulcers, and, because the proportions of perforations which occurred at the various time-intervals after onset were the same for both classes, we may deduce that the duodenal ulcers which perforated started at an earlier age than the gastric. This deduction is confirmed by the finding that 56·5% of the duodenal patients who perforated were under the age of forty at onset, as compared with 34·5% of gastric cases.

Having shown that a peptic ulcer should be regarded as probably chronic after ten years' duration, our suggestion that gastrectomy should then be seriously considered receives support from the analyses of hæmorrhage and perforation. About 55% of all hæmorrhages

TABLE XVI—PERFORATION IN RELATION TO DURATION OF ULCERATION

Years after onset	Gastric cases (78)	Duodenal cases (23)	Gastric deaths (26)	Duodenal deaths (10)
1–5	36 (*46%*)	12 (*52%*)	14	5
6–9	4 (*5%*)	1 (*4%*)	1	0
10 +	33 (*49%*)	10 (*44%*)	11	5

and 45% *of perforations in this series took place in cases* with a history of ten years' or more activity, and these included 7 deaths from bleeding and 16 from perforation. These figures alone, which do not reflect all the invalidism in uncomplicated cases, are sufficient to show the saving in lives and ill health which could have been effected by gastrectomy after ten years' duration at an early stage of chronicity. We must, of course, accept the risks from hæmorrhage and perforation early in the disease before chronicity is established; they are likely to carry a lower mortality today than they did in this series, but they are still significant.

Gastrectomy clearly should not be advised if a reasonable chance remains of an ulcer healing naturally, for the operation is severe, even at the hands of an expert. To Strode's (1948) provocative question "Why treat gastric ulcers medically?" we reply that about 30% *of the 231 gastric ulcers in this series healed without* surgical treatment; if he had specified chronic gastric ulcers we should have had no answer. We cannot discuss the mortality from gastrectomy except in the most general terms for the age and condition of the patient, the skill of the surgeon and anæsthetist, and the standard of preoperative and postoperative care are all variables. Nevertheless it may be said that the mortality in expert hands with the best ancillary facilities is probably less than 5%; but over the country as a whole it may be nearer 15%, and it rises with age.

The age and condition of the patient is certainly a major factor. A surgeon, however expert, cannot expect the same freedom from postoperative complications in elderly patients enfeebled by age and years of peptic ulceration that he can in younger subjects in relatively good condition. From our own observations we would *suggest that gastrectomy carries its lowest risks under* the age of fifty but thereafter they increase with age and become formidable over sixty-five. We have noted that in Hosford's (1949) series of 200 gastrectomies with 1 death, performed for peptic ulcer between 1936 and 1947, the average age of the patients was under fifty years. In Hedley Visick's (1948) series of 505 gastrectomies during the same period the total mortality was 5%; but it rose from 0·8% in the third decade to 5% in the fourth, 5·8% in the fifth, and 7·1% in the sixth or later.

It is evident, therefore, that the age of the patient should be reckoned with in conjunction with the duration of the ulcer when gastrectomy is considered. However, against the risk of postoperative death must be set the risk of death from complications of the ulcer if gastrectomy is not performed. Lewin and Truelove (1949) showed that the mortality from gastroduodenal hæmorrhage was profoundly influenced by the age of the patients and scarcely at all by the length of ulcer history. Thus in their series the fatality-rate did not exceed 10% in patients under fifty whatever their length of history, whereas it was not less than 22% for cases over fifty at any stage of the disease. We have not sufficient cases in this series to put forward similar statistics but the trend is the same. Thus in some cases it may be apparent that the risk of death from hæmorrhage or perforation may be greater than that of gastrectomy at a particular age.

Each case must be judged on individual circumstances, but in general we advocate gastrectomy for peptic ulcers after ten years' duration or, whenever possible, by the age of fifty. If this were done the invalidism, complications, and deaths from chronic peptic ulceration would be greatly diminished.

SUMMARY

The 356 cases of peptic ulcer, admitted as inpatients to Addenbrooke's Hospital during the years 1934–38 inclusive, have been reviewed in 1948–49.

Of this total 337 cases were accounted for or examined.

Medical treatment did not appear to have
the natural course of the disease.

Criteria for estimation of chronicity and
for hæmorrhage and perforation are given.

Gastrectomy is urged for all peptic ulcers
or more years' duration, preferably before the age

We are glad to acknowledge our indebtedness to P
Fisher, F.R.S., for statistical advice, to our colle
suggestions and access to their cases, and to the C
University Medical School for an expenses grant.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL, LO

IN *the course of routine bacteriological* exami
material from a maternity hospital it became
only that there was a high incidence of staph
infection among the infants in this hospital
that nearly all the infections were with
resistant strains of staphylococci.

In an attempt to trace the source of infe
carrier state of the staff of the hospital was
This led to the rather alarming discovery that
the staff were carrying *Staph. pyogenes,* and tha
the carriers were carrying penicillin-resistant str
was therefore decided to study staphylococcal
in this hospital in relation to the carrier stat
staff for a considerable length of time, and to
incidence of infection could be reduced by in
the aseptic technique used in the hospital. We re
the results of our investigations over eight mo

METHODS

All swabs from infective processes were plated out
blood-agar plates and penicillin ditch-plates. Th
this investigation the latter were made from 'Lem
plates, and the ditch, cut at one side of the plate,
with the same medium containing about 10 units of
per ml. They were prepared twenty-four hours or mo
use to allow some penicillin to diffuse out of the di
Oxford staphylococcus was streaked across every di
at the time of use as a control.

If staphylococci were present next day they we
for coagulase by the slide method of Cadness-Gra
(1943). Cultures of coagulase-positive staphylococci
referred to as *Staph. pyogenes*) were examined for
sensitivity. If, in such cultures, the ditch-plates s
colonies more resistant to penicillin than the Oxford
coccus, a single colony was picked from the blood-a
and streaked across a further ditch-plate to see w
mixture of penicillin-sensitive and penicillin-resistant
could be detected. *If all* colonies from a single
showed a similar reaction to penicillin, one was p
into lemco broth for further investigation. If both
sensitive and penicillin-resistant strains were presen
each was similarly picked off.

er State among Staff of Hospital.—The carrier state ntially pathogenic staphylococci in the hospital was ated by examining swabs from the anterior nares and the back of the wrist of the medical, nursing, and ic staff, and from the conjunctivæ of healthy babies. skin in every case, and the anterior nares in most moistened swabs were used. All these swabs were directly on to plain agar plates, which were incubated ht, and those from the skin and conjunctivæ were also ed in broth, which after overnight incubation was out. Where staphylococci were present they were ed by the slide coagulase test, and strains giving a e reaction were regarded as presumptive pathogens. ains, however, were later tested for α-hæmolysin (see : Where coagulase-positive staphylococci were present, er of colonies, if possible 10, were tested for penicillin ity by streaking across penicillin ditch-plates. If coagulase-positive staphylococci were present on the y plate, the growth was emulsified in broth and plated a similar ditch-plate to detect small numbers of peni- esistant staphylococci which might otherwise have been . Representative penicillin-sensitive and penicillin- nt colonies from each swab were picked off into lemco for further investigation.

rier State among Staff of London Store.—It was thought ble to compare the nasal carrier state of potentially genic staphylococci among hospital nurses with that of up of women living and working under the same roof ot connected with a hospital. Nasal swabs were therefore ned from 62 women working at a large London tment store and living in the attached hostel.

ha-hæmolysin.—All strains were tested for α-hæmolysin ction by the method of Gillespie and Simpson (1948), trains giving doubtful or negative results by this method further tested by the technique described by McFarlan).

ree and Type of Resistance to Penicillin.—All penicillin- nt strains from infective processes and 15 from carriers tested for penicillinase by the method of Barber (1947). strains were tested for penicillin sensitivity by serial ion in broth, two different sized inocula being used in case, as recommended by Gilson and Parker (1948). An mpt was made to determine the capacity of the same five ins to destroy penicillin. Equal portions of eighteen-hour ures were mixed separately with the same quantity of icillin solutions containing 500, 250, 100, and 50 units ml. The mixtures were incubated for an hour at 37°C then tested for penicillin content by the cylinder-plate hod.

ulphathiazole and Streptomycin Sensitivity.—All but one he strains from infective processes were tested for sensitivity ulphathiazole and streptomycin, and 22 strains from 18 riers were also tested for sensitivity to the former. Both ts were done on ditch-plates. For the former they were made of laked horse blood-agar as recommended by Harper and Cawston (1945), the ditch containing 1 in 5000 sulphathiazole, and for the latter ditches were cut in lemco agar plates containing 1000 µg. of streptomycin per ml. In both cases part of every ditch-plate was seeded with the Oxford staphylococcus as a control.

Phage-typing.—All strains were phage-typed by the method used at the Central Public Health Laboratory and with the same 25 filtrates. The method is based on the work of Wilson and Atkinson (1945).

INCIDENCE AND TYPE OF INFECTION

From the beginning of 1949 until the middle of September, when this investigation was concluded, there had been 950 births in the maternity unit under study. Of these 950 babies 133 developed neonatal conjunctivitis, superficial pyogenic skin lesions, or other probably staphylococcal infections. During this period 19 mothers were diagnosed as having mastitis, breast abscess, or furunculosis. The distribution of these infections throughout the period surveyed is given in table I, from which it is clear that, except for the rather high incidence of infection in February and the rather low one in August, the infection-rate has remained fairly constant for nine months.

The type of infection diagnosed clinically is listed in table II, which reveals the predominance of conjunctival and minor skin lesions in babies, and the absence of pemphigus neonatorum. In most of the cases the infection was very mild. Five, however, were sufficiently severe to require extensive treatment, and in these the patients were transferred to a pædiatric hospital. There were no deaths in the series, and no cases of permanent disablement.

STRAINS OF *Staph. pyogenes* ISOLATED FROM INFECTIVE PROCESSES

Swabs were examined from 56 cases of infection, and the results are given in table III. The only pathogen isolated from any of the specimens was *Staph. pyogenes*, and this organism was isolated from 42, in most cases in pure culture. The remaining 14 swabs were either sterile or yielded non-pathogenic organisms only. Many of these negative swabs came from patients under treat-

ment. In 36 of the 42 cultures of *Staph. pyogenes* all colonies tested were resistant to penicillin, whereas in only 3 cases were all colonies as sensitive to penicillin as the Oxford [illegible] patients both penicillin-sensiti[illegible] colonies were isolated. Thus on the basis of their reaction to penicillin 45 strains of *Staph. pyogenes* were isolated from 42 patients.

The degree of resistance to penicillin was in every case such that, when a single colony of a resistant strain was streaked across a penicillin ditch-plate, growth took place at least to the edge of the ditch and usually right across it. All the penicillin-resistant strains produced penicillinase. An attempt was made to measure the degree of resistance to penicillin of 5 of the resistant strains more accurately by serial dilution in broth. Two inocula of different sizes were used, since it is now well recognised (Luria 1946, Barber 1947) that the degree of resistance of penicillin-destroying strains when measured in the laboratory may vary many hundredfold according to the size of inoculum used. It was found that when the inoculum was about 1000 organisms, all 5 strains were inhibited by 0·5 unit of penicillin or less per ml., but, when the inoculum was 1,000,000 organisms or more, all 5 strains grew in at least 50 units of penicillin per ml. When young cultures of the same 5 strains were mixed with an equal quantity of a penicillin solution and the mixtures incubated at 37°C, they all destroyed about 250 units of penicillin in an hour.

All 45 strains of *Staph. pyogenes* were phage-typed. It will be seen from table III that 16 were not typable with the available filtrates. Of the 29 typable strains 26, consisting of 23 penicillin-resistant and 3 penicillin-sensitive strains, were phage-type 52A.

Of 44 strains tested for sensitivity to sulphathiazole, 42 had a sensitivity similar to that of the Oxford staphylococcus, but 2 strains were considerably more resistant. The same 44 strains were tested for sensitivity to streptomycin, and all showed a sensitivity similar to that of the Oxford staphylococcus.

All 45 strains were shown to produce α-toxin.

CARRIER STATE AMONG PATIENTS

At the beginning of the investigation conjunctival swabs were taken from all the babies at that time in the hospital who were free from infection. The results are given in table IV, which shows that *Staph. pyogenes* was isolated from 19 of the 35 babies examined. In 15 cases all colonies tested were resistant to penicillin, and in 1 both penicillin-sensitive and penicillin-resistant colonies were isolated. Thus from only 3 of the specimens yielding *Staph. pyogenes* were all colonies tested penicillin-sensitive.

As with the strains from infective processes, the predominant phage-type was 52A. As shown in table IV,
it was possible to type 12 of the 20 strains by
phage-method, and 10 of these 12 were type 52A.

In view of the work of Allison and Hobbs (
was thought unlikely that infants became infe
their mothers. The nasal carrier state of the
was not, therefore, investigated. Nasal and skin
were, however, taken from 6 mothers, all of whom
infected infants. All 6 carried *Staph. pyogenes*:
the nose and on the skin, 3 on the skin only, and 1
nose only. Three yielded only penicillin-resistant
2 of these were phage-type 52A and 1 non-typable.
other 3 were carrying penicillin-sensitive strains
1 of these was phage-type 3C, and the other
non-typable.

Of the 28 strains isolated from healthy babie
mothers 6 were non-toxigenic.

CARRIER STATE AMONG NURSES AND DOCTORS OF HO

The carrier state among the nurses and
doctors of the hospital was investigated on three
occasions. The carrier rates of *Staph. pyogenes*
penicillin-resistant *strains* on all three occasio
given in table v. The phage-types of the strains i
are shown in table VI. Since the hospital is a t
school for midwives, though the number of nurse
at any one time in the hospital remains about the
the staff is continually changing. About 12 of the
are permanent members of the staff, but new
midwives arrive in batches of 10–20 each mon
remain for three months. The carriers recor
table v do not therefore represent the same nu
each occasion. Only 8 nurses were examined on a
occasions; 32 were swabbed on the first two da
22 on the last two.

ill thus be seen that in spite of an almost complete e in the personnel making up the staff (40 of the abbed on Aug. 9 had entered the hospital since 22) the nasal carrier state in the hospital emained remarkably constant for six months. ghout the period penicillin-resistant organisms ge-type 52A have predominated.

table VII the nasal carrier state among the nurses is d to time of entry. This shows that the proportion ses carrying penicillin-resistant strains rises steadily length of stay in the hospital. Thus, of the nurses ed on the *first or second day after arrival less than* were carrying penicillin resistant strains of *Staph.* *es*, whereas nearly half of those who were swabbed six weeks in the hospital yielded such organisms. mong the nurses who had been in the hospital for months or more the proportion had risen to 66%. ing to the short stay of pupil midwives in the tal the nurses swabbed at the different times were not the same persons; 14 nurses, however, were d on the day of entry and again fourteen days On the day of entry penicillin-resistant strains of *pyogenes* were isolated from only 3, whereas after een days in the hospital these 3 and 5 others, making tal of 8, were carrying such organisms.

lphonamide sensitivity was tested in 22 strains ted from 18 nurses on Feb. 22; 19 showed a sensi-y to sulphathiazole similar to that of the Oxford hylococcus; 3 were considerably more resistant. the total 150 carrier strains isolated on the three ions 10 were non-toxigenic.

STUDY OF 10 HEAVY CARRIERS AMONG NURSES

nalysis of the swabs taken on Feb. 22 showed that y of the heaviest growths of potentially pathogenic phylococci ca[illegible] permanent nurses of the

TABLE VII—NASAL CARRIER STATE AMONG NURSES RELATED TO TIME SINCE ENTRY TO HOSPITAL

3 months or over ..	46	37	31

The nurses examined at different times were not always the same persons.

hospital. It was therefore decided to study the constancy of the carrier state in 10 such nurses. Starting on March 20, further nasal swabs were taken from these 10 nurses on three occasions at weekly intervals. Immediately after being swabbed on March 20, 5 of the nurses were given sulphathiazole cream, which they were asked to smear inside the anterior nares daily for four days. When the second swab was taken, three days after *stopping sulphathiazole treatment, 2 of the 5 treated* carriers had become negative and 2 showed a considerable reduction in carriage of *Staph. pyogenes*. The effect, however, was temporary, and by the following week *Staph. pyogenes* was again isolated in large numbers.

Of the 10 carriers studied in this group 9 had yielded penicillin-resistant strains of *Staph. pyogenes* of phage-type 52A on Feb. 22. From 6 this was the only strain isolated; 2 also yielded a penicillin-sensitive strain of the same phage-type, and 1 yielded a non-typable penicillin-sensitive strain. The remaining nurse carried a penicillin-sensitive strain belonging to phage-type 7/42E/44/52A. Apart from the temporary effect of sulphathiazole the staphylococcal carrier state in all these nurses remained almost unchanged. In 7 it remained entirely constant; 2 nurses originally carrying two strains appeared to lose one of the two, and 1 nurse yielding a single strain of penicillin-resistant phage-type 52A on Feb. 22 also yielded a penicillin-sensitive strain of phage-type 47C/52 on subsequent occasions.

Of these nurses 9 were swabbed again on May 17 or on Aug. 9 or on both dates; 2, who had been on holiday on May 17, had become negative on Aug. 9; the other 7 were still carrying strains similar to those isolated from them previously.

CARRIER STATE AMONG HOSPITAL DOMESTICS

On Feb. 22 nasal and skin swabs were taken from 17 of the hospital domestics. The group included ward cleaners and kitchen and laundry staff. The results are

TABLE VIII—CARRIER STATE AMONG DOMESTIC STAFF OF HOSPITAL

		Other groups	0	4

N.T., non-typable.

given in table VIII. It will at once be seen that the carrier state among the domestics is quite different from that among the nurses. Though *Staph. pyogenes* was isolated from the nose or skin of 12 of the domestics, only 2 yielded penicillin-resistant strains, both of which were non-typable. Only 2 of the 16 strains isolated belonged to phage-type 52A, and both of these were penicillin-sensitive.

All but 2 of the 16 strains carried by the domestic staff were α-toxigenic.

ASEPTIC TECHNIQUE

The main rules used to control the spread of infection in practice in the hospital at the beginning of this investigation were as follows:

Not more than 4 nurses handle any one baby between the time of delivery and the day of discharge.

Nurses and doctors, and cleaners when in the nursery, invariably wear masks which cover mouth and nose, and all nurses wear gowns.

Babies are washed in their cots and have separate towels.

Sterile cotton-wool is used during bathing. There is no communal changing table. Baths are disinfected with 'Dettol' after use.

Mothers are masked when they handle and feed their babies.

Feeding utensils are boiled after use.

Infected babies are immediately isolated in a small ward, and their attendants scrub up before and after handling them, and wear fresh gowns and masks, which are changed on leaving.

When each baby leaves, its blankets are laundered if the child has been healthy. If there has been any clinical infection, the complete bedding is autoclaved.

Ward floors throughout the hospital are swept with 'Di-dust,' a preparation resembling oily sawdust, which is intended to prevent dust particles from scattering. Babies are never in any ward which is being swept.

These measures are emphasised repeatedly to junior staff, and there is little doubt that they are fairly closely adhered to; but, since many of them depend on painstaking coöperation, and since constant close supervision is not always possible it seems likely that there are occasional examples of negligence.

These precautions seemed to us to compare favourably with those adopted in other maternity hospitals, but many possible sources of infection remain. When the carrier state of the nurses was discovered on Feb. 22, the hospital technique was discussed with one of the resident medical officers, and the following extra measures were recommended:

Masks should be changed more often, and any nurse blowing her nose should wash her hands and change her mask.

Nurses should wash up as if for a surgical operation before and after handling all babies, whether infected or not.

Nurses should all wear over their uniforms while on duty gowns which have been rendered impermeable by some process such as oiling.

The first two of these recommendations were immediately put into practice, but it was not thought possible to provide oiled gowns.

TREATMENT OF INFECTIONS

The vast majority of the lesions encountered have been mild and have readily responded to treatment, and perhaps for this reason the doctors have not practised a uniform or coördinated method of treatment. Occasionally local penicillin drops have been used in conjunctivitis, but usually bland lotions applied locally have been combined with systemic sulphadiazine or sulphadimidine ('Sulphamezathine'), and sometimes with penicillin by mouth. Gentian violet has often been used for skin lesions. It is worth noting that one of the five doctors who have treated these cases at various times during
the year expressed his opinion that penicillin
locally or systemically was the least successful m
of treatment he had used.

In accordance with modern practice in many mat
units, no prophylactic eye drops are used at birt

CARRIER STATE AMONG RESIDENTS OF A SHOP'S H

Swabs were taken from the anterior nares of 62 w
working in a large London store and living in the at
hostel. The total number of women living in the
is about 500; hence the 62 who volunteered fo
investigation only represent a small proportion
hostel population.

The results as regards the carriage of *Staph. py*
are given in table IX. It will be seen that just ove
the women were carrying *Staph. pyogenes*, but
case was any penicillin-resistant strain isolated. Di
phage-types were found, but 9 of the 15 typable s
were phage-type 52A.

ALPHA-TOXIN RESULTS

All 45 strains of *Staph. pyogenes* isolated from inf
processes were α-toxigenic, but 18 of 194 strains is
from carriers did *not* produce α-toxin. This is in agree
with the results of Schwabacher et al. (1945) in
study of the correlation between the coagulase
α-toxin production, and pathogenicity. These wo
found that of 178 strains of *Staph. pyogenes* isolated
cases of infection only 2·7% did not produce α
whereas 6·7–12·3% of strains isolated from ca
were coagulase-positive but not α-toxigenic.

DISCUSSION

We have now become accustomed to the fact
about half of all healthy adults carry potentially p
genic staphylococci in the anterior nares (Hallman
McFarlan 1938, Gillespie et al. 1939, Miles et al. 1
and that among hospital nurses the proportio
carriers is even higher (Miles et al. 1944, Allison
Hobbs 1947). In the hospital where the investiga
here recorded were made not only has the nasal car
rate of *Staph. pyogenes* among the nurses been persist
58–68% but throughout the period of observation 70
of the carriers have carried penicillin-resistant st
In addition, phage-typing of the strains of *Staph. pyo*
isolated has shown that nearly all the typable peni
resistant strains belonged to the single phage-type
This constant carrier state has been maintained
spite of the fact that, since the hospital
training school for midwives, the nurses are con-
changing.

udy of 65 strains isolated both from infected and the conjunctivæ of healthy babies showed 5 were penicillin-resistant, and once again nearly able strains were type 52A.

ems fairly clear from these results that a single of penicillin-resistant *Staph. pyogenes* phage-type spreading round the hospital. Further evidence s was obtained when the staphylococcal carriage the nurses was related to the length of time each had spent in the hospital. This showed that. s only 4 of 23 nurses on entering the hospital were ng penicillin-resistant strains of *Staph. pyogenes*, 16 who had been in the hospital for three months or arried such organisms.

s now generally accepted that penicillin-resistant lococcal infection is much more common among ts who have been in hospital for some time than patients or outpatients (Harley et al. 1946, Forbes Barber and Whitehead 1949, Rountree and n 1949). Barber and Rozwadowska-Dowzenko and Forbes (1949) in this country and Rountree omson (1949) in Australia have related this finding e high nasal carriage-rate of penicillin-resistant s of *Staph. pyogenes* among the nurses of hospitals, ave suggested that this is one of the main sources ection. The present investigations support this stion. It seems likely that nurses in many other tals would also show a high carriage-rate of penicillin-nt *Staph. pyogenes* if similarly investigated.

studies of Voureka and Hughes (1949) and tree and Tomson (1949) and the present investiga-of a London departmental store show that the nce of penicillin-resistant strains of *Staph. pyogenes* noses of the population at large is nothing like so as that in hospital communities. The incidence of illin-resistant strains among the domestics here ed was also low. Though some of these worked in ard, none had close contact with infants, and they in different quarters from the nurses.

e question arises what can be done to make such a tal a more healthy environment. Since the work of pie et al. (1939), Miles et al. (1944), and Williams) it is generally accepted that the main reservoir aph. pyogenes is the anterior nares. The way in a nasal carrier spreads infection has been studied are and Mackenzie (1946) and Duguid and Wallace). These workers have shown that as a rule the r does not infect another person directly from the but infects his clothing or bedding and skin and from sources infects other people.

e aseptic technique used in the present hospital fulfils of the recommendations of Allison and Hobbs (1947) he prevention of the spread of pemphigus neona-m. The additional measures put into practice at the of March did not appreciably affect the incidence fection among the infants. There was, however, a ficant decrease in the skin carriage of *Staph. pyogenes* the nurses in May and August which may have associated with these extra precautions. Further sures are impossible with the present facilities and available. There is no gross overcrowding of ents, and light and ventilation in the hospital are derate.

llison and Hobbs (1947) suggest that the technical culties of adequate preventive measures in nurseries so great that it might be better to give up such favour of mother and infant being nursed together small ward or cubicle. This, however, would entail e rebuilding of most maternity hospitals.

n the meantime it can only be emphasised that nicillin-resistant staphylococcal infections are nearly ays cases of hospital cross-infection. The prevention of both is therefore the same and depends on the hygiene and aseptic control of the hospital.

SUMMARY

In a maternity hospital studied for eight months the incidence of infection among the infants was 14% and remained fairly steady throughout the period of observation.

Staph. pyogenes was isolated from 42 cases of infection; 36 of these yielded penicillin-resistant strains only; 3 yielded penicillin-sensitive strains only; 3 yielded both penicillin-sensitive and penicillin-resistant strains.

Conjunctival swabs taken from 35 healthy infants yielded cultures of *Staph. pyogenes* in 19 cases; in 15 all colonies tested were penicillin-resistant; in 3 all were penicillin-sensitive; in 1 penicillin-sensitive and penicillin-resistant colonies were isolated.

The carrier state of the doctors and nurses of the hospital was studied on three separate occasions at three-monthly intervals. The nasal carrier-rate of *Staph. pyogenes* was throughout 58–68%, and 70–80% of the carriers carried penicillin-resistant strains on each occasion. The skin (back of wrist) carriage-rate, which was 51% on Feb. 22, was only 19% on May 17, and 10% on Aug. 9.

Phage-typing of strains isolated from all these sources showed that in each case the great majority of the typable penicillin-resistant organisms belonged to the same phage-type, 52A.

The carrier state among the domestic staff of the hospital was examined on one occasion. *Staph. pyogenes* was isolated from the nose or skin of 12 out of 17 tested, but only 2 yielded penicillin-resistant strains.

For comparative purposes nasal swabs were taken from 62 women working in a large London department store and living in an attached hostel. Though 33 were carrying *Staph. pyogenes*, none yielded a penicillin-resistant strain.

All of 44 strains isolated from infective processes were shown to have a sensitivity to streptomycin similar to that of the Oxford staphylococcus.

The same 44 strains were tested for sensitivity to sulphathiazole; 42 had a sensitivity similar to that of the Oxford staphylococcus, but 2 were considerably more resistant. Of 22 strains isolated from carriers among the nurses 3 were resistant to sulphathiazole.

We wish to thank the doctors and nurses of the hospital for their coöperation; Prof. Ronald Hare and Dr. Joseph Bamforth for advice; and Dr. R. E. O. Williams and the staff of the Staphylococcal Reference Laboratory for teaching us the technique of phage-typing staphylococci, supplying us with a set of filtrates, and checking many of our results.

ANTIPYRETIC ACTION OF CRYOGENINE

GEOFFREY BOURNE
M.D. Lond., F.R.C.P.
PHYSICIAN AND PHYSICIAN-IN-CHARGE OF THE CARDIOLOGICAL DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, LONDON

THE treatment of fever as such used to be an integral and important part of the treatment of disease, but the advent of bacteriology has so altered the emphasis of therapeutics that the treatment of fever *as a symptom* has largely fallen out of repute. This is understandable, for it is logical to treat the cause of the fever, where this is known, rather than the fever itself. It must, however, be remembered that fever, especially when high, is not always beneficial and may be deleterious to the patient. It necessitates a considerable increase in the basal metabolic rate; it promotes the loss of water from the body by both skin and lungs; it may be responsible for sleeplessness; and, if it is intermittent, the resulting sweats and rigors can exhaust the patient.

When I was his house-physician Dr. J. H. Drysdale prescribed 'Cryogenine' in a case of lymphadenoma. The temperature was high, swinging, and accompanied by severe sweats and rigors, and the general clinical picture resembled that of severe tertian malaria. The effect of the cryogenine, given on two or three days only, was striking, for the temperature fell to normal and remained so for several weeks afterwards, with great benefit to the patient's general condition: The recollection of this case suggested a retrial of cryogenine in lymphatic leukæmia accompanied by considerable fever (case 1). The effect of the drug was similar to that in the case of lymphadenoma mentioned above, and it was therefore given in several other cases.

Cryogenine is phenylsemicarbazide ($C_6H_5NH{\cdot}NH{\cdot}CONH_2$) in the form of white crystals soluble 1 in 100 of water, and 1 in 25 of alcohol 90%. The dose is gr. 3–24 (0·2–1·5 g.) up to gr. 40 (2·5 g.) a day.

Cryogenine was introduced by Lumière and Chevrotier (1902) as a new antipyretic. Gélibert (1902) described it as a white crystalline powder, odourless, and stable in solution. It was non-toxic to animals in intravenous doses of 2 g. per kg. of body-weight. In normal rabbits the temperature fell from 39·9 to 34·1°C after a dose of 0·05 cg. per kg. The cryogenine was excreted in about twenty-four hours, and there was no change in the pulse-rate or respiration-rate. In tuberculous guineapigs a smaller dose produced a demonstrable but smaller fall in the temperature, but there was no change in the course of the tuberculosis. In man there was sweating after doses of gr. 15.

Dumarest (1902) tried cryogenine in typhoid fever, influenza, acute rheumatism, and suppuration, and found its action definite but transitory. In "nervous fever" its action was very good, and in the fever of tuberculosis, especially in the less acute cases, the therapeutic effect was to reduce the temperature with benefit to the patient.

Noé (1903) cited Boy-Teissier and Bruneau (1903) to the effect that a single dose of 0·8–2·0 g. could bring down the temperature in 1 or 2 hours for 6–18 hours in many cases. After several successive doses the temperature would remain down for as long as 4 days.

Carrière (1905) confirmed that the fever of active tuberculosis was especially well reduced and controlled by cryogenine without unpleasant side actions. He found a slight leucocytosis and a slight increase in the output of urine, and a slight lowering of the blood-pressure. (These last two observations might equally be the result of the reduction in the fever.) Carrière confirmed the reputed action of cryogenine on rabbits and guineapigs, and found no bad effect on the appetite, bowel action, gastric secretion, blood-count, or urinary output of normal people. In normal people the temperature would fall within twenty-four hours after a single dose of cryogenine. Carrière tried cryogenine not only in typhoid fever but also in acute enteritis, acute tonsillitis, and acute bronchitis, in all of which conditions its antipyretic action was definite. In bronchopneumonia the effect on the temperature was variable, but in acute tuberculous pleurisy and *active* pulmonary tuberculosis the effect was very pronounced.

Masseguin (1903) confirmed its action in active tube both pulmonary and peritoneal, and made a special of its action in "nervous fever" complicating h paralysis.

Martinet (1903) compared cryogenine with other pyretics, such as antipyrine, acetanilide, phenacetin, 'Pyramidon,' and concluded that it was better in its less dangerous, and less liable to produce adverse

Little more seems to have been written about cry until Sainsbury (1915) reported its beneficial action in f phthisis. He found that a single dose of gr. 10–15 might an effect which lasted several days.

There was a further interval until Leulier and (1935) tried cryogenine in experimental fever produced pigeons with dinitrophenol 10–12 mg. per kg. of body-Their experiments, with controls, proved that in this type fever cryogenine would reduce the temperature measura

Graubner (1936) reported five cases of febrile ph treated with cryogenine in which the temperature definitely lowered during treatment.

Perelli (1937) reported the good effect of cryogenine antipyretic in undulant fever; it lowered the tempe and relieved the associated headache and anorexia.

Hutchison and Hilton (1948) write as follows: pulmonary tuberculosis fever is an indication for rest in and if it continues it is usually necessary to increase t of the diseased part by artificial pneumothorax or some means. The rise of temperature usually occurs in the afternoon and it can be prevented by giving gr 10 of genine about 2 P.M. In advanced cases it sometimes hap that the patient has not the strength to react, and so is no evening rise of temperature and an inverse ty therefore a serious sign. The inverse type of temper produced by cryogenine has not the same significance. the drug is stopped the temperature usually rises again in some cases it remains normal. *It is useful for its ps logical effect on patients who worry about their temperat*

Pisani and Tesi (1946) reported that cryogenine was not only in tuberculous cases with fever but also in pr of uncertain origin. They cited 210 cases of active t culosis and 60 cases of undiagnosed fever treated benefi with cryogenine.

The question naturally arises whether the non-u cryogenine and similar drugs may be due to their or other unpleasant effects. In the published re there are very few indications of any such complicat Carrière (1903) noted in one case a miliary skin erupti a child, aged 14, who was given gr. 7½ three times for several days, and hæmoglobinuria in one case Noé (1903) noted vomiting very occasionally and pro sweating but no collapse. Martinet (1903) rega cryogenine as safer than other febrifuges, and P and Tesi (1946) state that, compared with amidopyri had a much longer action and was much less toxic. his series of 270 cases he found no toxic evidence in case causing him to stop or withhold cryogenine.

CASE-RECORDS

Case 1.—A man, aged 56, was admitted seriously ill fever, profuse perspiration, and headache. Two years viously he had first noted in both groins lumps which slightly, but otherwise he had felt reasonably well spleen had been found to be enlarged and a blood co which had given the following result, suggested lymph leukæmia: red cells 4,800,000 per c. mm., Hb 92%, and cells 160,000 per c.mm., of which 100,000 were lymphoc

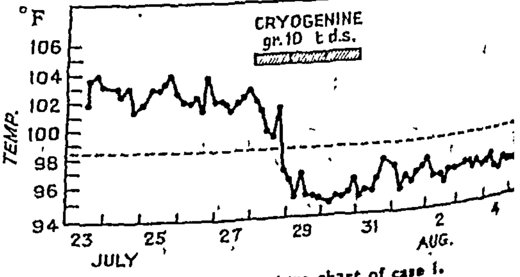

Fig. 1—Temperature chart of case 1.

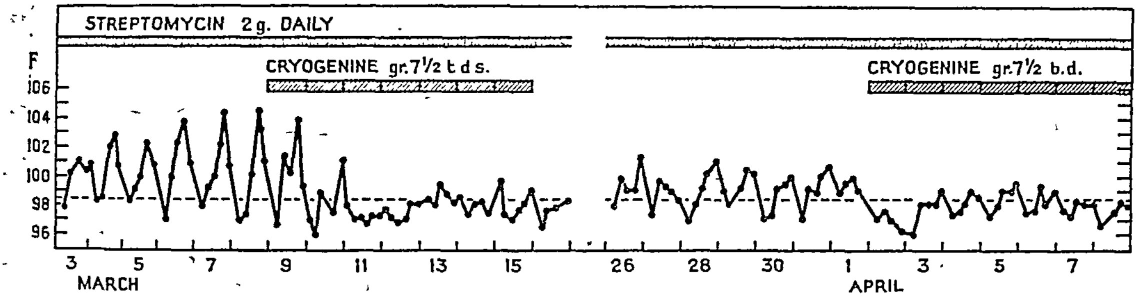

Fig. 3—Temperature chart of case 3.

tient had received deep X-ray therapy, and the leuco- unt had fallen to 7600 per c.mm. He had remained itil his symptoms had returned fifteen months before ion, and he had received a further course of deep therapy. He had improved again, but nine months admission he had had pneumonia which had been fully treated with penicillin. Eight months before ion he had begun to have fever, headache, and loss of e. The fever had remitted after seven days, and had turned. Three weeks before admission he had again febrile and was admitted to hospital.

dmission his spleen and lymphatic glands were enlarged. d-count gave red cells 3,260,000 per c.mm., Hb 46%, hite cells 4200 per c.mm. (3276 neutrophils, 798 ocytes, and 126 monocytes.)

tment.—In view of the high fever, which alone was distressing him, the patient was given cryogenine t.d.s. for three days. The patient became afebrile and went home feeling very much better.

e months later he was admitted with an acute exacerba- om which he died. Though the clinical picture was f lymphatic leukæmia, the histological features, post n, were those of a systematised reticulosis showing in the spleen, liver, lymph-nodes, and bone-marrow.

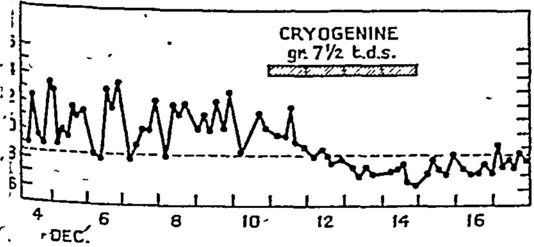

Fig. 2—Temperature chart of case 2.

pleomorphic picture, together with giant cells and sis, suggests that the diagnosis lies between Hodgkin's e and polymorphic reticulum-celled sarcoma. In spite e absence of eosinophils polymorphic reticulum-celled ma cannot be diagnosed in the absence of invasion of unding structures.

se 2.—A married woman, aged 34, had been, three years e admission, an inpatient under my care, with rheumatoid itis and patent ductus arteriosus. Her general condition een poor, and she had had the typical but not severe nities of rheumatoid arthritis affecting the joints of the s, wrists, knees, and ankles. In view of her rather poor que ligation of the ductus had been postponed. A year her erythrocyte-sedimentation rate (E.S.R.) being now 9, fever being absent, and her general condition being r, the patient had been transferred to the care of Mr. O. S. s, who had tied the ductus arteriosus. She had made a good recovery from this and had been discharged without udible ductus murmur. *Seven months before admission,* and swelling had returned to her joints, and she had me generally less well.

n hospital she developed a considerable fever, the tempera- averaging 102°F but occasionally rising to 103°F. The e of this was uncertain, but the E.S.R., which on admission 32 mm. in an hour, rose to 50 mm. in an hour. A blood- ture was sterile, and no abnormality was seen in a chest iogram. There was no appreciable leucocytosis. A white-cell count at this time was between 7300 and 11,000 per c.mm. The urine was sterile.

Treatment.—Because the symptoms were being aggravated by the persistent fever, cryogenine gr. 7½ t.d.s. was given for four days. The temperature fell to normal in twenty-four hours (fig. 2), and the patient felt much better. After a further three weeks' observation, during which she remained afebrile, she was discharged.

Case 3.—An unmarried girl, aged 22, was admitted after having been ill two and a half months with persistent dry cough, severe night sweats, rapid loss of weight, and extreme fatigue at the end of her day's work as a barmaid.

On admission she was very ill and was obviously severely wasted. Her temperature was spiky and remained for the first five weeks of her time in hospital between 99° and 103°F. Her heart-rate averaged 130, and her respirations 35 per min. Radioscopy of her chest showed a widespread miliary tuberculosis.

Treatment.—The patient was given streptomycin 2 g. daily by injection, but this had no demonstrable effect on her fever or heart-rate. At the end of her fifth week in hospital it was considered that the severe swinging fever, with its associated profuse sweating, was a definite clinical handicap to her condition; therefore cryogenine gr. 7½ t.d.s. was given for a week. The effect was dramatic, the temperature remaining below 99·4°F for the whole of that period after the first two days (fig. 3). Three days after the discontinuance of cryogenine the temperature began to rise again, but remained at a definitely lower level, the average mean reading being below 100°F. After a further fortnight cryogenine gr. 7½ was given twice daily for a fortnight, and during this time the temperature remained below 99·2°F (fig. 3). Cryogenine was then discontinued, and the temperature mounted once more. The course of the tuberculosis was slowed by the streptomycin, but the patient died after having been in hospital just over five months.

Case 4.—A man, aged 54, had begun, thirteen months before admission, to get a little breathless on exertion while at his work as a railwayman. Nine months before admission he had begun to cough, without sputum, and this had disturbed his night's sleep. *Three months before admission he had* begun to produce occasionally bloodstained sputum. He had then become increasingly breathless, had had to stop work, and had been admitted to the East Surrey Hospital, Redhill, for investigation, whence he was transferred to St. Bartholomew's.

On examination he was rather wasted, his trachea was slightly deviated to the right, and the right side of his chest was flattened and moved poorly. Physical signs of pulmonary collapse were present at the right base. Clubbing of the fingers

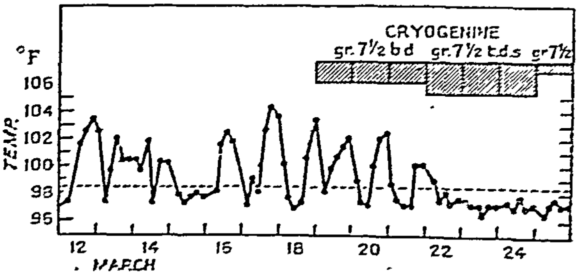

Fig. 4—Temperature chart of case 4.

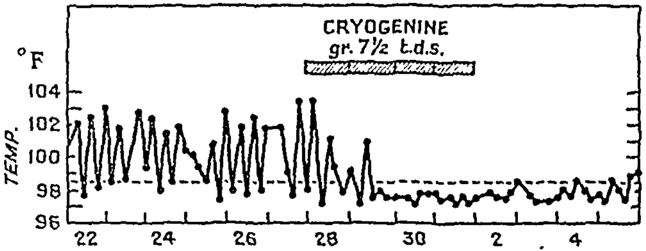

Fig. 5—Temperature chart of case 5.

was well marked. Radiography showed a definite shadow in the posterior part of the right lung, presumably due to a mixture of collapse and consolidation; the picture was typical of a neoplasm. Bronchoscopy (Mr. O. S. Tubbs) showed constriction of the right upper bronchus, which was nearly occluded by a proliferative growth, sections of which showed it to be an oat-celled carcinoma.

Progress.—The patient had fever during the whole of his three-month stay in hospital; it was moderate at first, but halfway through March there was a swinging temperature between 97° and 103°F. Since clinically the patient did not seem to have severe toxæmia with this fever, and since his white-cell count during this time fell from 15,300 to 9500 per c.mm., cryogenine gr. $7^1/_2$ was given twice daily for three days, t.d.s. for three days, and twice daily for one day. Not only did the temperature fall to normal after a week (fig. 4), but it remained nearly normal for the rest of the patient's two and a half weeks' stay in hospital, except for a few occasions on which it rose to 99·0–99·8°F. The patient was then discharged.

Case 5.—A married woman, aged 57, had ten months before admission felt abnormally tired and begun to lose her appetite. Eight weeks before admission she had begun to have a dull ache to the left of the umbilicus, to feel nauseated, and to have severe attacks of sweating, chiefly at night. These attacks had been followed by shivering. The nausea and fatigue had increased, and she had been referred to Dr. Bodley Scott, who has kindly allowed me to add her to this series of cases.

On admission to the Florence Nightingale Hospital the patient had fever rising to 102°F at night associated with rigors. Her spleen was enlarged. She was treated by chemotherapy and with penicillin, which cured a urinary infection by *Strep. viridans* but had no effect on the fever or rigors. After investigation for typhoid and *Brucella abortus* infections, which were negative, a biopsy specimen from a gland on the right side of the neck suggested an infective condition and was not typical of a reticulosis.

Treatment.—In the absence of a diagnosis the patient was given cryogenine gr. $7^1/_2$ t.d.s. for four days, which caused an immediate disappearance of the fever (fig. 5), the temperature remaining down for three weeks. In view of the severe anæmia and the enlarged spleen the patient was referred to Mr. Allan Hunt for abdominal exploration, since it was felt that splenectomy might cut short the hæmolytic process. The spleen was removed, and its histological and pathological appearance suggested lymphosarcoma.

DISCUSSION

Perhaps the most interesting point about the action of cryogenine in this series is that a small dose seems to be sufficient to reduce the temperature, and that, after this fall has been achieved, the effect continues for a much longer time than can be explained on general principles by a continued action of the cryogenine. This is seen in all of the cases here described except case 3 (miliary tuberculosis). In this case cryogenine reduced the fever each time it was given; but, when cryogenine was withheld, the temperature rose within twenty-four hours to its previous higher level.

Cryogenine seems to be an effective antipyretic in some cases, and should therefore be considered in cases in which reduction of the temperature may be important or when "nervous fever" is suspected. The rather dangerous diagnosis of "nervous fever" should only be made after an extremely full investigation has proved negative, in patients in whom the E.S.R. and w count are normal in spite of considerable fever, in the temperature has been carefully checked by a sible nurse, and in whom there is other evidence of h or psychological abnormality. Further, cryogenine be particularly useful in controlling the fever of the reticuloses where the raised temperature apparently as part of the clinical picture irres of any intercurrent infection.

The fact that cryogenine exerts a rapid effect persists for days or weeks, long after the cryo must have been either excreted or neutralised by body, suggests that it has some action on the heating centre. It is arguable that sometimes fever is to a minor disorder of this centre and that cryo renders it more sensitive to the physiological pr and nervous impulses which control the temperatu accurately in healthy people.

VITAMIN E IN INTERMITTENT CLAUDICATION

A. Hall Ratcliffe
M.A., B.Sc., D.Phil. Oxfd
LECTURER IN EXPERIMENTAL METHODS, DEPARTMEN
SURGERY, UNIVERSITY OF MANCHESTER

The connexion between the tocopherols (vitami and the development of the vascular system was repo by Adamstone (1931) from the study of chick embr and later by Mason (1943) from rat embryos.

The clinical improvement of cases of senile vu vaginitis after treatment with large doses of vitami was reported by Shute (1942). The appearance of bio specimens of vulvar tissue after such treatment sugge to Shute that the improvement was due to prolifera of new capillaries or the reopening of old colla capillaries. From the time-lag of 2–4 weeks be improvement took place and on physiological gro it was considered that proliferation of new capill was the more likely.

The effect of tocopherol therapy on vascular dis of the legs was reported by Shute et al. (1948). Cli studies of various conditions, including thrombophleb indolent ulcers, early gangrene, and "thromboang obliterans," suggested that vitamin E was of valu such conditions.

The clinical results of vitamin-E therapy in 81 cas obliterative vascular disease of the legs with intermit claudication have been analysed by Boyd et al. (19 It is from the data compiled on these and subsequ patients treated from the neurovascular clinic at Manchester Royal Infirmary that the following c have been selected.

INTERMITTENT CLAUDICATION

A routine clinical examination is made of all pati complaining of intermittent claudication, the res being entered on a standard form. The data recor include the location of the pain, the history of the co gress of the condition, the state of nutrition of the e presence or absence of pulses, and oscillometric s at various points on the leg. These data enable lerlying vascular lesion and the affected muscle be recognised (Boyd et al. 1949). It then remains severity of the condition to be assessed before the nt can be decided. Where the state of nutrition that the limb is in danger, the primary effort e directed to saving the leg. Where the limb is langer, the treatment is aimed at the relief of the ive manifestation of pain which interferes with ient's daily life. The circulatory deficiency of the st therefore be assessed in the light of the demand n the patient's blood-supply. The required data tained by testing the patient's ability to walk controlled conditions.

patient is exercised by walking either over a known of the hospital corridors or on a "claudicometer," ng of a platform over which runs an endless or belt driven by an electric motor through a iously variable V-belt system. The rate of walking led by the patient as being his normal pace.

n the claudication pain begins, the distance is y the observer. The patient is not allowed to rest urged to continue walking as far as possible, meanescribing the subjective phenomena. The distance h the patient eventually halts is also noted. From a obtained it is possible to classify the severity of ndition as belonging to one of three types.

rationale of the classification depends on a conion of the events taking place in a muscle during e. The blood-supply to a muscle at rest is scanty increases considerably with exercise (Krogh 1922). muscle is exercised under conditions of ischæmia, sults (Lewis et al. 1929). Though the exact mechaof the vasodilatation and the production of pain ot been fully described, it cannot be doubted he initiating event is the accumulation of metain the contracting muscle (Hamilton 1947). With ing exercise the level of metabolites will become when the rate of elimination is equal to the rate duction. With normal blood-supply stabilisation place below the threshold of pain; but in the ant, with reduced blood-supply, the pain threshold hed before stabilisation. The level at which equi can be attained depends on the relation between supply and demand, and it is this level which ines the severity of the pain and the clinical type dication.

THREE CLINICAL TYPES

e *I.*—In this type the blood-supply and demand out equal. Before maximum vasodilatation is ed the pain threshold is crossed, but equilibrium is ally reached below the threshold. On walking, pe-I claudicant complains of the onset of pain, but ntinuing to walk he announces, usually with some se, that the pain has disappeared. That the equin is just below the pain threshold can be demond by increasing the rate of walking above the l, causing the pain to return.

pe *II.*—Here equilibrium is reached above the hold of pain. On continuing to walk after the onset e claudication the patient says that the intensity of pain remains much the same. Eventually he stops ing, not because of any increase in intensity but use of the persistence of the pain. Naturally the nt with the less intense pain tends to walk further the patient with the more severe pain.

pe *III.*—Equilibrium is never reached with this ; the deficiency of blood-supply is such that the becomes intolerable before that point. The type-III ent, on being urged on after the onset of claudication, es that the pain is growing worse, and he halts a short ance further on, obviously in extreme pain.

SELECTION OF CASES

It is beyond the scope of this paper to discuss the treatment of intermittent claudication. Details are given in the paper by Boyd et al. (1949). Symptomatic relief is in general obtained in the type-I patient by any treatment in which the patient has confidence leading to his taking the increased exercise necessary to develop his collateral circulation; in the type-II patient by methods designed to increase the blood-supply beyond the demand (lumbar sympathectomy gives the best results); in the type-III patient by methods designed to reduce the demand for blood (the blood-supply cannot be increased to bridge the gap).

In the type-II claudicant, though sympathectomy gives the greatest improvement, it is often contraindicated for other reasons. It is for this type of patient that vitamin-E therapy is used. The treatment recommended by the neurovascular clinic consists of the synthetic α-tocopherol ('Ephynal' Roche) 400 mg. daily by mouth.

The criteria for the inclusion of cases in this series are as follows:

1. Type-II claudicants for whom sympathectomy is contraindicated.
2. The patient must not have had any other treatment.
3. The halting distance must not exceed 500 yards—the reason for this restriction is apparent from the method of assessment of results.

SELECTION OF CONTROLS

During the investigation of intermittent claudication some patients were given substances—e.g., nicotinic acid —which it was believed might relieve the condition. Certain patients for whom vitamin E was recommended were either not given the treatment by their own doctors or were given inadequate doses. For purposes of comparison with the results obtained from vitamin-E therapy it has been decided to class all these patients as having been on a placebo treatment. For inclusion in this control series the same criteria have been applied as for those cases treated with ephynal.

ASSESSMENT OF RESULTS

The patient's chief concern is the interference with his daily life by the pain on walking. As the treatment of the cases in this series was directed to the relief of this pain, assessment of results has been made on the patient's ability to walk. The cases were reviewed after about three months' treatment, when a walking test like that used for the original typing was made. It was considered that to walk 880 yards was in most cases economically desirable. The criterion for improvement was thus arbitrarily fixed as the ability to walk a minimum of 880 yards with either complete freedom from pain or what the patient regarded as very minor discomfort. All other cases have been classed as "not improved," though certain of the patients on vitamin-E therapy more than doubled their original halting distance.

RESULTS

Of the patients for whom α-tocopherol therapy had been recommended by the neurovascular clinic 41 fulfilled all the requirements necessary for inclusion in this series. The walking test after three months' treatment showed that 34 were "improved" and 7 were "not improved."

The controls numbered 25. The walking test showed that 5 of these were "improved" and 20 "not improved."

The significance of these observations can be judged most simply by a two-by-two contingency table. The modified form, quoted by Fisher and Yates (1948), for experimental data involving small numbers gives $\chi^2=37{\cdot}4$. From the tables in the same book for $n=1$ and $p=0{\cdot}001$, $\chi^2=10{\cdot}8$. The results may therefore be classed as "highly significant."

DISCUSSION

The literature of α-tocopherol therapy is vast and highly controversial. The situation has been further complicated by the appearance of articles in the popular press hailing vitamin E as a substance which to all intents and purposes is a universal remedy.

In November, 1946, the Council of the College of Physicians and Surgeons of Ontario considered claims made by the Shute brothers for the usefulness of vitamin-E therapy in cardiovascular disease. The conclusion of the council was the equivalent of the old Scottish verdict of "not proven," with about the same damning result (Noble 1947). But, whatever the findings about the treatment of cardiovascular conditions in general, it is difficult to explain the improvement in certain cases cited by Vogelsang et al. (1947, 1948) as being due to causes other than vitamin-E therapy.

A complete review of the arguments which have been advanced for and against α-tocopherol therapy is not feasible here. Certain points, however, demand mention. The most important of these is that, to be effective, vitamin E must be given in large doses and for a long time. Both from published reports and from a study of the cases treated from the neurovascular clinic it seems that the optimum dosage is about 400 mg. daily. This should be given in the form of α-tocopherol, the biological activity of the β- and γ-tocopherols being considerably less (Mason 1943). One of the most striking observations in connexion with vitamin-E therapy is the delay before the patient begins to notice any improvement. In obliterative vascular disease this delay is from four to eight weeks, the average being about six weeks. Negative evidence of the effectiveness of vitamin-E therapy with doses of less than 400 mg. daily for periods shorter than three months must therefore be considered inadmissible. Conversely, reports of success with small doses or treatment for a short time must also be suspect.

In diseases of the circulatory system the number of variables involved may be large and the assessment of progress hazardous. In reporting 13 cases of cardiovascular lesions Levy and Boas (1948) stress the difficulty of estimating the improvement. Even when, as in patients with intermittent claudication, a yardstick of improvement—albeit an artificial one—is available it must be used with care. Thus it would be possible to present a series of type-I cases in which 100% success was obtained; but other substances are equally successful in this type. A series of type-III cases judged by the walking test would be a complete failure. It should be observed, however, that in certain type-III patients to whom vitamin E was given, though their ability to walk did not increase sufficiently to be considered as "improved," a considerable change for the better was noticed in the nutrition of the feet.

Of the 7 "not improved" patients in this series one, who had originally been diagnosed as having diffuse obliterative arteritis, later had a secondary popliteal thrombosis, which would be sufficient to explain the lack of improvement. Examination of the case-records of the other 6 did not reveal any common factor which might suggest that vitamin-E therapy would not succeed.

From the economic point of view it must be admitted that α-tocopherol is expensive. Presumably therefore it should be used only where there is a reasonable hope of success that could not be achieved by other means. Even in these cases, however, to give inadequate doses for short periods is just as wasteful as to use the substance haphazardly.

SUMMARY

Cases of obliterative vascular disease leading to intermittent claudication were selected from the records of the neurovascular clinic at the Manchester Royal Infirmary.

The criteria for the selection of cases for with vitamin E and of the controls are detailed.

The results were assessed after three months' by testing the ability to walk. Patients treatment had been forced to halt at less than were classed as "improved" if after tr could walk more than 880 yards.

Of 41 cases in the treated group 34 were of 25 cases in the control group 5 were χ^2 test shows that the results may be classed as "significant."

Points in connexion with the use of including the necessity for high dosage treatment, are discussed.

For permission to publish these cases I wish Prof. A. M. Boyd, professor of surgery in the U Manchester and director of the neurovascular cl Manchester Royal Infirmary.

INHIBITION BY METHIONINE O TOXICITY OF CRYSTALS FRO AGENISED ZEIN

OBSERVATIONS ON LEUCONOSTOC MESEN

J. G. HEATHCOTE
B.Sc. Manc., A.R.I.C.

From the Research Association of British Flou Cereals Research Station, St. Albans

THE isolation from agenised zein of a substance which is toxic to rabbits and dogs wa recently from these laboratories (Bentley et It was shown further (Heathcote 1949a) crystals are markedly toxic to the bacterium, *mesenteroides* P 60, even at concentrations 5 µg. per ml. of liquid medium, the bacterial agglutinated and acid production substantiall Still smaller concentrations—e.g., 1–5 µg. produced milder effects resembling the a effects of certain chemicals on acid-producin

EFFECT OF ADDING METHIONINE TO CULTURE M TOXICITY OF CRYSTALS TO *L. mesenteroide*

EXPERIMENT I

Concentration of toxic crystals in full-growth medium (µg./ml.)	*dl*-Methionine added to medium (µg./ml.)	Mean titre (ml. of 0·01*N* NaOH)	Toxic of ag or di in nu ba
Nil	..	1·13	++
200	..	0·11	
50	..	0·57	
50	ca. 1000	1·04	

EXPERIMENT II

Nil	..	2·70	
20	..	1·38	
20	100	2·44	
20	500	2·44	
20	1000	3·02	

1945, Heathcote 1949b), which are believed to be an unbalanced mixture of amino-acids.

reliminary work on the mode of action of the toxic s on this bacterium relatively large doses of individual amino-acids, including those known to ential for its growth, were added to the culture n. The amino-acids examined were: *dl*-alanine, ine monohydrochloride, *dl*-aspartic acid, *l*-cystine, eine, glycine, *l*-glutamic acid hydrochloride, sodium tate, *l*-histidine monohydrochloride, *l*-hydroxy- . *dl*-isoleucine, *dl*-leucine, *dl*-lysine, *dl*-methionine, ylalanine, *dl*-proline, *dl*-serine, *dl*-threonine, *dl*-phane, *l*-tyrosine, and *dl*-valine.

hese amino-acids, methionine alone showed any on the toxicity. The addition of sufficient nine to the medium nullified the toxic effect estored acid production as illustrated in the panying table.

n these and other experiments it appears that the substance formed by the action of nitrogen tri-le on zein is absorbed by the bacteria in similar r to methionine but that when methionine is t in excess it is preferentially absorbed. Conse-y, it is not unlikely that the toxic substance is to methionine in chemical composition, in which t is based on the methionyl residue of the zein le. More detailed evidence implicating methionine essential reactant is contained in a further paper hese laboratories (*Nature, Lond.* in the press).

e nitrogen trichloride can act as an oxidising the simple oxidation products of methionine— nine sulphoxide and methionine sulphone—were for toxicity towards *L. mesenteroides* P 60. The ne was found to be more toxic than the sulphoxide he toxicity of both compounds was negligible red with that of the crystals isolated from agenised The crystals cannot, therefore, be identified with of these two compounds. This result is in keeping the comparative harmlessness of oxidised peptone n et al. 1947), containing methionine sulphone, it is used as a medium for microbiological assays, . *mesenteroides* P 60 as the test organism.

ther evidence suggesting a relationship between known substance and methionine is derived from onine assays on hydrolysates of the crystals red from agenised zein. Hydrolysis with 2·5*N* HCl autoclave at 15 lb. pressure for 6, 12, and 24 hours, h causing some reduction in toxicity, did not etely destroy it. Treatment with 6*N* HCl for 68 at 110°C, however, completely removed all toxicity. a hydrolysate of crystals (0·5 mg.) prepared in ay the excess acid was removed on a water bath he hydrolysate was neutralised and made to volume. olution was tested in the usual manner (Heathcote) to ensure the complete absence of toxicity ds *L. mesenteroides* P 60 and was then assayed ethionine using the same organism and a supple-d medium of oxidised peptone ('Difco'). The result e microbiological assay indicated a methionine-ement value equivalent to 0·8% of *l*-methionine. r chromatograms on the hydrolysed material failed eal the presence of free methionine. The inference ore is that the hydrolysis produces some substance ssing only partial methionine-replacement value he organism.

is work supports the conclusion in an earlier paper these laboratories (Bentley et al. 1948): that it is methionine portion of a protein molecule which gives xic properties when it is treated with nitrogen loride.

SUMMARY

he addition of methionine arrests the toxic effect on conostoc *mesenteroides* P 60 of the crystals isolated agenised zein. This finding is in keeping with the view that it is the methionine portion of the protein molecule which is essential for the production of the toxic substance.

HOSPITAL MEDICAL SCHOOL, LONDON

Thomsen and Plum (1939), reviewing eosinophilic leukæmia, summarised 14 published cases, since when a further 9 cases have been described:

Drennan and Biggart (1930) described a case of eosinophilic response to an irritant in a boy, aged 15 years, whose leucocytes numbered 61,000–73,000 per c.mm. (eosinophils 28–70%).

Stephens (1935) described a case of acute eosinophilic leukæmia in a girl, aged 17, with 130,000 leucocytes per c.mm. (eosinophils 68%), and Reye (1940) another in a boy, aged 5½ years, with 160,000 leucocytes per c.mm. (eosinophils 72%).

Lepak (1940) described eosinophilic leukæmia, possibly complicated by tuberculosis, in a man, aged 41, with 9500–40,300 leucocytes per c.mm. (eosinophils 15–30%).

Bass (1941) reported the case of a boy, aged 6½ years, with 9400–51,000 leucocytes per c.mm. (eosinophils 29–70%).

Goehl (1942) reported a case of eosinophilic leukæmia in a male, aged 18, with 7900–190,000 leucocytes per c.mm. (eosinophils 5–88%).

Fenner (1943) reported one in a male, aged 19, with 56,000–63,000 leucocytes per c.mm. (eosinophils 55%).

Friedman et al. (1944) reported one in a boy, aged 11 years, with 126,000 leucocytes per c.mm. (eosinophils 82%).

Hodgson et al. (1945) reported a case of myeloid leukæmia, probably eosinophilic, in a woman, aged 44, with 46,000 leucocytes per c.mm. (eosinophils 43%).

Sex and Age.—Of the 23 cases 18 have been in males. The age-incidence ranges from 1 year 4 months to 55 years, the distribution being 6 cases in the age-group 1–14 years, 4 in that of 15–20 years, 2 in that of 25–35 years, and 9 in that of 40 years or more; in 2 cases the age was not given.

Duration.—The duration of the illness, where stated, was in 5 cases more than two years, and in 13 cases was from a few days to fourteen months, suggesting that eosinophilic leukæmia tends to run an acute rather than a chronic course.

Eosinophilia.—The percentage of eosinophils ranged from 41 to 70, with an average of 63. The white-cell count fluctuated from normal to more than 200,000 per c.mm., the average being about 76,000.

Liver, Spleen, and Lymph-glands.—Enlargement of the liver, spleen, and lymph-glands was not constant. Any combination might be present or absent at any time of the disease. In nearly every published case attention was drawn to the maturity of the eosinophils in the peripheral circulation, the coarseness and heaping of the granules, and the vacuolation. Eosinophil and neutrophil metamyelocytes, myelocytes, myeloblasts, and normoblasts were met with in the serial counts in all the published cases. The myeloblasts ranged from 0·5 to 9% of the differential count. 2 cases (Stephens 1935, Thomsen and Plum 1939) terminated in a myeloblastic crisis.

Marrow.—The marrow picture varied. In Thomsen and Plum's (1939) case 40% "stem" cells were found, and in Stephens's (1935) cases 98% "blast" cells; Goehl (1942) found many myeloblasts, and Hodgson et al. (1945) 7% myeloblasts. However, Bass (1941), Fenner (1943), and Friedman et al. (1944) reported that the marrow was normal except for a great preponderance of mature eosinophils, as was also found in the present case.

Necropsy.—Widespread infiltration of voluntary muscle, myocardium, pulmonary alveolar walls, splenic pulp, lymph-glands, liver, and kidneys by mature eosinophils was found. The cause of death in most cases was heart-failure due to infiltration. Mural thrombi were found in 4 cases, those of Reye (1940), Thomsen and Plum (1939), and Stephens (1935), and in the second case published by Hay and Evans (1929).

CASE-RECORD

Case 1.—A boy, aged 1 year 4 months, was admitted on Jan. 1, 1948, with bronchopneumonia and mild rickets. Radiography of his chest showed patchy areas of consolidation in both lower lobes. Blood examination showed Hb 61% (Haden) (9·52 g. per 100 ml.), white cells 17,800 per c.mm. (neutrophils 26%, lymphocytes 51%, eosinophils 20%, monocytes 3%, basophils 0).

Jan. 9.—Chest clearing. Liver and spleen impalpable. Lymph-glands not enlarged. Mantoux 1/1000 negative. White cells 20,000 per c.mm. (neutrophils 12%, lymphocytes 76%, eosinophils 12%, monocytes 0, basophils 0). Hb 72% (Haden) (11·32 g. per 100 ml.).

Feb. 4.—Neither ova nor worms were discovered on repeated stool examinations. Casoni intradermal test negative. White cells 44,000 per c.mm. (neutrophils 13%, lymphocytes 30%, eosinophils 55%, monocytes 1%, basophils 1%).

Feb. 13.—A short course of arsenic was begun. Liver three finger-breadths below the costal margin. Spleen impalpable. Small hard discrete glands in axilla, neck, and groin. White cells 33,000 per c.mm. (neutrophils 10%, lymphocytes 45%, *eosinophils 45%, basophils 0, monocytes 0). Hb 62% (Haden)* (9·67 g. per 100 ml.).

Feb. 22.—Spleen impalpable. Liver still three finger-breadths below the costal margin. Its edge was thin and sharp. White cells 35,000 per c.mm. (neutrophils 12%, lymphocytes 33%, eosinophils 53%, monocytes 2%, basophils 0). Normoblasts 1%. Hb 70% (Haden) (10·92 g. per 100 ml.).

Feb. 27.—Glands in the right axilla were enlarged. Liver as before. White cells 35,600 per c.mm. (neutrophils 11% lymphocytes 36%, eosinophils 50%, monocytes 1%, basophils 0, eosinophil myelocytes 2%). Wassermann reaction negative.

March 1.—The patient was discharged. White cells 24,300 per c.mm. (neutrophils 20%, lymphocytes 50%, eosinophils 28%, monocytes 2%, basophils 0). Hb 66% (Haden) (10·3 g. per 100 ml.).

March 31.—The patient attended hospital outpatients with another attack of bronchitis. Spleen palpable. Liver three finger-breadths below the costal margin. *White* cells 81,800 per c.mm. (neutrophils 17%, lymphocytes 24%, eosinophils 54%, monocytes 1%, basophils 0, neutrophil myelocytes 3%, eosinophil metamyelocytes 1%). Normoblasts 1%. *Hb 65% (Haden) (10·14 g. per 100 ml.).*

June 14.—The patient was seen again for the first time since March. Spleen impalpable. Liver still three finger-breadths below the costal margin. Lymphatic glands still enlarged. White cells 49,600 per c.mm. (neutrophils 33%, lymphocytes 35%, eosinophils 30%, monocytes 2%, basophils 0). Hb 66% (Haden) (10·3 g. per 100 ml.).

June 26.—White cells 22,200 per c.mm. (neutrophils 16%, lymphocytes 47%, eosinophils 36%, monocytes 0, basophils 1%). The tibial marrow contained hæmocytoblasts 0·5%, erythroblasts 3%, normoblasts 8%, myeloblasts 1·5%, early myelocytes 6%, neutrophil myelocytes 3%, neutrophil metamyelocytes 4%, neutrophil polymorphs 13%, eosinophil myelocytes 11%, eosinophil metamyelocytes 9%, eosinophil polymorphs 35%, lymphocytes 5·5%, monocytes 1·5%. Leuco-erythroblastic ratio 7·5 to 1.

The eosinophils seen in the peripheral blood and marrow smears were mostly bilobed mature cells. The granules were coarse and tended to "heap" in the cytoplasm. There was well-marked vacuolation. The nucleus was
and the cytoplasm did not stain.

The cells called early myelocytes in the marrow
somewhat of a puzzle; except for a loss of intensity
in the nucleus and the presence of granules, they c
been called myeloblasts. The nucleus filled the cell
one pole, where there was a slight indentation, and
paler than the myeloblast. At the indentation ther
a few granules, some eosinophilic and others ma
basophilic.

Examination of Relations.—A history of allergy w
obtained. The mother's white-cell count gave 8400 leu
per c.mm. (neutrophils 72%, lymphocytes 18%, mon
6%, eosinophils 4%, basophils 0). The father's whit
were 4700 per c.mm. (neutrophils 56%, lymphocytes
monocytes 2%, eosinophils 0, basophils 1%). *The pa*
sister had 11,250 white cells per c.mm. (neutrophils
lymphocytes 16%, monocytes 6%, eosinophils 4%, ba
1%). His twin brother had 13,100 white cells per
(neutrophils 23%, lymphocytes 70%, monocytes 5%,
phils 2%, basophils 0). The diagnosis was th
eosinophilic leukæmia.

FAMILIAL EOSINOPHILIA

Familial eosinophilia is much rarer than eosin
leukæmia. Stewart (1933), reviewing the published
reported 4 of his own, Malmberg (1939) added

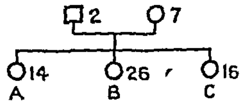

Fig. 1.

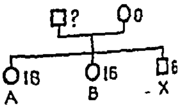

Fig. 2.

Atmar (1940) published 1 with a report on a
specimen of the liver. Bowman (1941) describe
families in which the diagnosis might reasonal
entertained. The number of families with f
eosinophilia reported hitherto is fourteen (not inc
the one here presented). The familial incide
the four families described since Stewart's (1933)

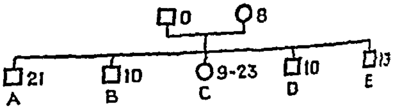

Fig. 3.

is shown in figs. 1–4. In Bowman's patient (fig.
eosinophils were of adult type, the spleen and l
nodes were enlarged at various times, and the m
showed eosinophil hyperplasia. The patient a
two sisters were subject to urticaria. In Atmar's
family no parasites were isolated and the Wass
reaction was negative. When the patient was op
on for repair of a ventral hernia, the liver was s

parenchyma with mature eosinophils.

Inheritance.—Analysis of the published family hi
shows that eosinophilia was transmitted throu
mother in 11 families, through the father in
through both parents in 2.

Allergy.—Of the families reported, 5 show alle
one or more members (Klinkert 1911, Stewart
Bowman 1941).

Eosinophilia.—The average percentage of eo-in
in the differential white-cell counts was 21%, the
being from 4 to 80%. The total white-cell
varied from normal to 46,000 per c.mm. Inexp
transient eosinophil leucocytoses lasting up to
months were encountered in the affected families.

ot accompanied by any signs of ill health. As the phil percentage rose, the neutrophil-count fell, ie result that at maximal eosinophil-counts there ı absolute neutropenia. The eosinophils in the eral circulation were normal adult cells and l in no way from those seen in routine counts. s in contradistinction to the picture presented in philic leukæmia. In none of the families reported ny immature eosinophils noted in the smears.

r, Spleen, and Lymph-glands.—At various times, erved members of the families, the liver, spleen. mph-glands enlarged temporarily.

row.—The marrow presented an orderly pro- ve maturation in which the emphasis in the lar elements was on the eosinophil at the expense neutrophil.

CASE-RECORD

e 2.—A boy. aged 2 years 4 months, was referred to ients on Feb. 27, 1948, with a history of pallor for nine s. He was otherwise apparently healthy. There was inite family history of allergy. but his mother had had rh" for many years. The patient had had bouts of itis with wheezing. A blood-count had been done on .6 privately. The white-cell count was given with no on of a differential count. Eosinophilia had thus been l—a lesson on the necessity of looking at every film. *examination* the patient appeared pale, his liver edge st palpable, but his spleen was impalpable. The left al glands were slightly enlarged, but the other lymph- s were normal. A blood-count showed red cells 5,060,000 mm., Hb 66% (Haldane), colour-index 0 65, white cells) per c.mm. (polymorphs 11·5%, lymphocytes 25·5%, ytes 1%, eosinophils 59·5%, basophils 2·5%).

rch 5.—The patient was admitted for investigation. nx test 1/1000 negative. Erythrocyte-sedimentation mm. in 1 hour (Westergren).

rch 8.—Hb 66%, white cells 22,500 per c.mm. (poly- s 16%, lymphocytes 24%, monocytes 2·5%, eosinophils plasma cells 0·5%). Three stools were examined, but r ova nor worms were seen. No obvious cause for the philia was found.

imination of Relations.—The patient's father had 6400 cells per c.mm. (polymorphs 68%, lymphocytes 27%, cytes 4%, eosinophils 0·5%. basophils 0 5%), and his er had 6800 white cells per c.mm. (polymorphs 54%, hocytes 28·5%, monocytes 3·5%, eosinophils 11·5%, hils 2 5%).

rrow.—The patient's tibial marrow gave a total nuclear of 58,500 per c.mm. (hæmocytoblasts 0·2%, pro-erythro- s 0·2%, normoblasts 3·8%, myeloblasts 0·6%. pre- cytes 1·4%, neutrophil myelocytes 0·9%, eosinophil

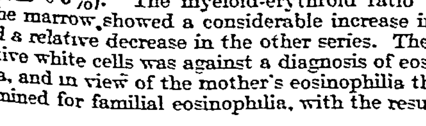

Fig. 5.

ocytes 6·8%, neutrophil metamyelocytes 1·8%, neutro- polymorphs 16·0%, eosinophil leucocytes 34·9%, basophil cytes 0·2%, lymphocytes 28·9%. monocytes 4·0%, a cells 0·3%). The myeloid-erythroid ratio was 15·6 . The marrow showed a considerable increase in eosino- and a relative decrease in the other series. The absence mitive white cells was against a diagnosis of eosinophilic æmia, and in view of the mother's eosinophilia the family examined for familial eosinophilia, with the result shown g. 5.

The blood-group genotypes of the patient and his parents e as follows: father A,r r, mother B,R R, and the patient R r.

March 25.—The patient was discharged unimproved. with diagnosis of familial eosinophilia.

DISCUSSION

Hæmatologists have been reluctant to admit the istence of eosinophilic leukæmia as a pathological tity. It does not exhibit the characteristics which they pect of a leukæmia, and other eosinophilias reported as possible leukæmias have, in the light of newer knowledge, been found to belong to Löffler's syndrome or tropical eosinophilia. Nevertheless that this condition is a form of leukæmia is strongly suggested by the following facts: (1) the eosinophil is abnormal: (2) each case has shown immature forms in the peripheral bloodstream if followed long enough—in contradistinction to familial eosinophilia. where, in spite of a persistent leucocytosis, immaturity is never seen, and the eosinophil looks normal; (3) the condition can end as a myeloblastic state; and (4) the marrow films show a reversion to immaturity. which is not seen in familial eosinophilia.

The point of departure from ordinary myelogenous leukæmia seems to be at the early myelocyte or premyelocyte stage. An unusual type of cell was noted in the marrow by Thomsen and Plum (1939) and Stephens (1935) and in the present case. It has been described as a "stem" cell by Thomsen and Plum (1939), who state that it does not resemble a leukæmia cell or a normal marrow cell, and describe it as having a sharply defined and deeply staining nucleus and a poorly defined cytoplasm with minute blue granules at the periphery. Stephens (1935) calls it a "blast" cell. with a nucleus paler than a myeloblast and a faintly basophilic cytoplasm with no granulation. In our case it was about as large as a myeloblast, the nucleus was sharply defined and stained less deeply than the blast cell, the cytoplasmic rim was faintly basophilic, there was an indentation at one pole and there were a few large coarse mixed eosinophil and basophil granules. In the two cases published by Thomsen and Plum (1939) and Stephens (1935) the cells were seen in a terminal myeloblastic phase of the disease, and in our case during the chronic stage. Possibly the different descriptions are due to different stages of maturity.

Infiltration.—Death in eosinophilic leukæmia is due to infiltration by the adult leucocyte of organs essential to life, particularly the myocardium. Though the eosinophil is usually referred to as a tissue-fluid leucocyte, its power of infiltration in the adult form does not seem to be fully appreciated. This power of infiltration has been shown in both eosinophilic leukæmia and familial eosinophilia, and therefore seems to be distinctive of the cell, suggesting that it has primarily a tissue function; whether this is a "detoxication" or not is hardly germane to the present discussion. The extent of the infiltration seems to depend on the degree of the leucocytosis and its duration; that the infiltrative capacity of the eosinophil is of general importance is suggested by a case reported by Barrie and Anderson (1948), who describe pyloric hypertrophy due to massive eosinophilic infiltration in a patient with persistent eosinophilic leucocytosis. They conclude that the appearance of the pylorus was due to an organic intestinal allergic reaction; the possibility that it might have been secondary to familial eosinophilia, or even an eosinophilic leukæmia, was not considered. Up to now these two forms of eosinophilia have been classed as a hæmatological curiosity, but familial eosinophilia may be more widespread than is suspected, and its presence may be a more rational explanation for some of the focal lesions hitherto described. The release of relatively large amounts of histamine set free by the death of the eosinophils may explain the localised areas of necrosis which so often accompany focal infiltration by eosinophils.

Allergy.—Whether the allergic reactions commonly noted in familial eosinophilia are coincidental with, causes of, or caused by the eosinophilia is difficult to decide. Their incidence is too great for coincidence to be a plausible explanation; and, if inherited sensitivity was the cause of familial eosinophilia, one would expect the condition to be much commoner than it is. It therefore seems more reasonable to conclude that the existence and death of a large number of eosinophils in the body may be responsible for the allergic manifestations, which are an expression of systemic histamine activity. This point raises the question of eosinophilic leucocytosis in allergy. In view of the many cases of allergy seen, and the relative paucity of counts showing much eosinophilia, we suggest that, where allergy coexists with a high degree of eosinophilia, other members of the family should be investigated for familial eosinophilia. Possibly a separate class of " allergics " exists who are such because of their blood condition and not because of any sensitivity to bacteria, dust, or pollen.

SUMMARY

A case of eosinophilic leukæmia and one of familial eosinophilia are described, and previously published cases reviewed.

The evidence suggests that eosinophilic leukæmia is an entity.

Attention is drawn to the infiltrative power of the adult eosinophil.

The relation of allergy to familial eosinophilia is discussed.

We acknowledge gratefully the help of Dr. A. Doyne Bell, under whose care both patients were admitted.

WOOLWICH GROUP OF HOSPITALS

Lewin and Wassén [1] report that the combined injection of deoxycortone acetate and ascorbic acid caused temporary improvement in cases of rheumatoid arthritis. Our object here is simply to state that we have been able to confirm these results in a considerable proportion of cases. Further work is proceeding on the mode of action of these substances and the physiological changes they produce and will be reported in due course. We have studied 23 cases, using the recommended dosage of 5 mg. of deoxycortone intramuscularly followed within five minutes by 1 g. of ascorbic acid given intravenously, and these are grouped below according as to whether there was a striking response, an improvement, or a failure to react favourably at all.

STRIKING RESPONSE

CASE 1.—A woman of 34 with polyarthritis of five years' standing and the left shoulder restricted to a painful limit of 150° in abduction acquired a full free painless arc within ten minutes. The improvement was maintained for seven hours, and control injections with water the next day failed to elicit any response, much to the patient's disappointment.

CASE 2.—A woman of 38 with polyarthritis of three years' standing. Fifteen minutes after injection she was able to close one fist for the first time in seven months, there was a great increase in excursion of the wrists with disappearance of forearm spasm, and the left knee bent easily into full flexion, an increase of 20°. *All pain went, the* generally relaxed, and this improvement lasted for The same effect was reproduced two days later, but day an injection of ascorbic acid + saline gave only improvement which she found disappointing. The effect was reproduced with deoxycortone + as after two days.

CASE 3.—A woman of 56 with polyarthritis of twelve standing, in great pain, with many tender joints, and to walk without assistance. Two hours after injectio could walk unaided, all pain had gone, and both fists be closed for the first time for nine months. T lasted twenty-four hours. Four days later the initial was reproduced, but after another three days a injection of saline + saline gave no obvious improve Some improvement persisted in this case; the swelling ulnar deviation of the metacarpophalangeal joints hand cleared up and she was able to get her shoes on for the first time in six months.

CASE 4.—A woman of 44 with quiescent arthritis in joints and a warm swollen foot and ankle in which movement was prevented by pain and spasm. Afte minutes a full painless range was obtained and main for several hours, and the swelling decreased. The considerable subjective improvement and the gait was

CASE 5.—A rather obtuse and sceptical working m 60 with quiescent polyarthritis and a right shoulder rest by pain and spasm to 140° of abduction. Improv began fifteen minutes after injection and in two hours was an enormous subjective change. He felt "as joints had been well oiled," there was a complete easy at the shoulder, and there was an obvious ease of mo in the wrists and loss of forearm spasm.

CASE 6.—A man of 45 with polyarthritis and shoulders grossly limited in abduction and rotation relieved of pain within an hour and acquired almo rotation and greatly increased abduction movement.

IMPROVED

CASES 7–21.—All of these lost some pain and some completely relieved, there was lessening or disappearan spasm, and in some cases measurable increase in movement. These cases include a boy with Still's d and a [illegible] thritis. One woman wh had a [illegible] response lasting twent hours then developed a painful exacerbation lastin three days.

FAILURES

CASE 22.—A man of 55 with polyarthritis of ten standing.

CASE 23.—A man of 26 with quiescent ankylosing sp litis of four years' duration.

DISCUSSION

The natural history of rheumatoid arthritis has been fully studied owing to the practical difficul following cases over the long and variable cour the disease without giving any treatment. The g view, however, is that 25% of cases undergo sponta recovery, 50% improve, and 25% deteriorate de treatment.[2] To prove beyond any possible doub value of a treatment it is necessary to watch a series of cases over a period with careful control to establish a significantly better improvement ra the treated cases. But in our experience, and we be the experience is general, although the disease may a comparatively sudden onset, it never undergoes a sudden improvement as we have witnessed, in cases within a few hours or even minutes of inje of deoxycortone and ascorbic acid. We know instance where such rapid loss of pain and joint tende and increase in range and ease of movement have occ either spontaneously or after any form of treat If it be shown that such changes occur after injections a very remarkable fact has been establi and with such a dramatic effect it does not need a series of controls to establish this fact.

We have taken the following features as criter improvement.

---

[1] Lewin, E., Wassén, E. *Lancet*, Nov. 26, p. 993.

[2] A Primer of Arthritis: Committee of American Rheum Association, 1942.

e subjective impressions of the patient.—These, though ition not to be objectively assessed, are equally not nored. Of our 23 patients 21 felt better in them- the result of a general feeling of well-being plus a or complete loss of local pain and spasm. Several became obviously relaxed and at ease.

e relief of pain, both on the patient's statement and observations during passive movement of affected

ening of spasm.—This is best appreciated if the r moves the wrist-joint with one hand, keeping ers of his other hand resting on the volar surface of the s forearm. The relaxation of the wrist flexors after n was frequently noted, and even with cold wrists h there were fixed obstacles to motion at the extremes ited range the same range was now traversed without or apprehension. In the better cases it was notable ns of gross underlying pathological changes, in the of grating and crepitus, which had previously been appeared for the first time.

provement of joint movement includes an increase in ed range, a greater ease of motion, a loss of apprehension ing, and, in 3 cases, the overcoming of a resistance houlder motion which had been present for several years.

are satisfied from these early observations that on of deoxycortone acetate and ascorbic acid temporary clinical improvement in a considerable tion of cases of rheumatoid arthritis. This improve- was dramatic in only 6 of our 23 patients, and the observer of a series which did not include such cases might fail to notice instances of slighter improvement. We refer to what appears to be a specific pattern of response indicated by increased ease and comfort in active and passive movement, the decrease of regional pain and spasm, and an indefinable but genuine improvement in the patient's sense of well-being. We noted in case 2 that if deoxycortone + ascorbic acid gave a good result on one day, ascorbic acid + saline might give a moderate improvement the next day, and we feel that enough of the deoxycortone may linger for a day or two to enable this to happen, so that a longer interval is desirable between control injections.

SUMMARY

23 cases of polyarthritis, mostly instances of rheumatoid arthritis, have been treated with deoxycortone acetate and ascorbic acid injections. 6 of these exhibited rapid striking improvement lasting several hours, 15 were temporarily improved, and 2 failed to respond. We regard these findings as substantiating the claims of Lewin and Wassén that these substances given in conjunction exert a beneficial action in some cases of rheumatoid arthritis.

Six of the patients were seen at the Kensington Institute of Rheumatic Diseases through the kindness of Dr. Kenneth Stone.

Medical Societies

ROYAL SOCIETY OF MEDICINE

stroduodenal Hæmorrhage as a Surgical *Emergency*

surgical section of the Royal Society of Medicine n Dec. 7, under the chairmanship of Mr. DIGBY BERLAIN, president of the section, to discuss duodenal hæmorrhage as a surgical emergency.

A. H. DOUTHWAITE said that such hæmorrhage ited one of the most difficult and terrible problems dicine; it could not be solved by laying down atic rules. He proposed to confine himself to onsideration of peptic ulceration, but there were important points in the differential diagnosis.

hosis of the liver might be difficult to diagnose. ic indigestion was quite commonly associated with nd the liver and spleen were not always palpable, ally since the spleen shrinks with hæmorrhage. -function tests were unreliable in an exsanguinated it. In some cases peptic ulcer complicated cirrhosis result of the gastritis which was usually associated it. Chronic nephritis with uræmia was another e of trouble. The urine might not contain albumin ery case, but the patient was drowsy, and the le, in clear contrast with cases of peptic ulceration. dirty. The heart was enlarged and the blood- was always over 100 mg. per 100 ml. Two other tions to remember were pulmonary tuberculosis, might be complicated by acute gastric ulcer, and tension; but this last was a quite uncommon e of bleeding from the stomach.

ferent figures and opinions about the results of tment were difficult to compare because so much nded on the criterion of severity. The hæmoglobin entage might be used, but it was *unreliable*; *if the* ing on admission was 50% or more and the patient not become restless or the pulse-rate rise, or if no e red stools were passed, Dr. Douthwaite adopted ical treatment, and in a series of 35 cases managed this way only 1 had died. Treatment consisted in administration of fluids, blood-transfusion if the moglobin fell below 40%, and rest. He believed in rphine, but it sometimes had undesirable side- ects such as vomiting and pyloric spasm, and he refore combined it with papaverine gr. 2 and phenobarbitone gr. 3, all given together by intramuscular injection—somewhat of a blunderbuss, but effective.

Dr. Douthwaite thought it impossible to decide which patients would continue to bleed and which would not. He had treated 7 patients with a hæmoglobin of 30% or less. They had been cold, sweating, and mentally confused; the blood-pressure had usually been under 70 mm. Hg. 6 of them had died directly as the result of hæmorrhage, despite transfusion: the 1 who survived was aged 35. 6 similar cases operated on had all died, 4 of them on the table. The mechanical and technical difficulties of stopping the bleeding by surgical methods were very great. He had come to believe that in cases with a hæmoglobin of 50% in which the pulse-rate rose or there was a further fall of hæmoglobin, surgical treatment should be given without any further delay. Only so could surgical results improve.

If a patient with a chronic ulcer had bled and recovered on two occasions, operation should be done in a quiescent interval. The ulcer was likely to be chronic in 90% of cases; but it was not always easy to be sure. This difficulty was often due to the unreliable history given by patients of poor intelligence. If a chronic ulcer was shown radiologically in a patient aged 55 or more who suffered from arteriosclerosis, operation was indicated after only one hæmorrhage.

One cause of surgical failures was the poor general condition of patients with chronic ulcer. They sometimes developed serious deficiencies in their plasma-proteins which gravely undermined their resistance to the strain of operation. Curare was a dangerous drug not only in emergency operations for hæmorrhage but also in elective gastric operations.

Mr. NORMAN TANNER said that gastroduodenal bleeding as a surgical emergency resolved itself into three problems: (1) for which lesions is surgery indicated? (2) when is surgery required? (3) what surgical technique is appropriate? At St. James' Hospital between 1941 and 1949 there had been 836 cases of gastroduodenal hæmorrhage, constituted as follows:

Gastric ulcer	364	Simple gastric neoplasm ..	5
Duodenal ulcer	258	Gastric diverticulum.. ..	1
Anastomotic ulcer ..	40	Pancreatitis	2
Œsophageal ulcer.. ..	2	Carcinoma of pancreas ..	2
Gastritis	53	Aneurysm of aorta	1
Carcinoma of stomach ..	29	Uræmia (chronic nephritis)	1
Portal hypertension ..	31	Uncertain, duodenal diverticulum, &c.	44
Hiatal hernia	3		

The first five causes might be grouped together since they present with similar histories so that preoperative differential diagnosis is uncertain and the treatment is similar. Surgery must play a most important part in the treatment of this group. In carcinoma of the stomach the bleeding usually ceased spontaneously unless the growth was inoperable. Portal hypertension was best treated medically in the first instance, and in some cases the bleeding might be checked by direct pressure on the œsophageal varices produced by the balloon of an adapted Miller-Abbott tube (Rowntree's method). But in some cases emergency surgery was needed.

In solving the problem of when surgery was required, three possible courses were open to the clinician.

1. He might treat all cases medically except those which were certain to die without operation. No patient who would have recovered naturally would lose his life because of unnecessary surgical interference, but on the other hand some patients would die of bleeding while the physician made up his mind; and the majority of those who would have died under purely medical treatment would still die because surgery was too late.

2. The second course might be called selective surgical intervention and was the one most generally chosen nowadays. Medical treatment was given first, but the surgeon was called in for those cases which bled repeatedly or persistently.

3. The third course might be called the Finsterer method. Every patient with a chronic peptic ulcer who was admitted with severe hæmorrhage was operated on at once.

In order to test the efficiency of each of these three courses under constant conditions, Mr. Tanner arranged in 1941 for all cases of gastroduodenal hæmorrhage to be admitted to his own wards. A standard régime was laid down but from time to time the surgical policy was changed. The results were as follows:

	No. of cases	*Percentage over 60 yrs of age*	*Percentage operated on*	*Over-all mortality %*
1941 to 1943: operation avoided as far as possible	193	33	5	10
December, 1943, to June, 1944: earlier operation, always gastrectomy	60	33	15	20
June, 1944, to December, 1947: operation early, simplest to stop bleeding	312	35	11	11
January, 1948, to September, 1949: "Finsterer"	183	42	60	7

Two special points about these figures were the high average age of the patients and the omission of the operative mortality. This was low, but it was omitted because the over-all mortality was the more important. The operative mortality depended on the type of risk accepted.

The problem of surgical technique concerned mainly the peptic-ulcer group, but Mr. Tanner had devised an operation which he had used for œsophageal varices in quiescent intervals, and he suggested that it might be adapted as an emergency treatment for hæmorrhage. He called it "transgastric portocaval phlebotomy." Its object was to interrupt the collateral channels carrying blood from the high-pressure portal system up to the œsophageal veins, and thus to reduce the pressure in these veins to that of the caval system. It consisted in transecting the stomach (and with it all the vessels in its wall), dividing all the vasa brevia and the left gastric vein, and then re-anastomosing the stomach.

For bleeding peptic ulcer the operation of choice was gastrectomy, provided that one was well acquainted with the operation and particularly with its difficulties in duodenal ulcer. For very large gastric ulcers in debilitated patients it was sometimes necessary to restrict the operation to a local attack on the ulcer itself, and for a time he had treated duodenal ulcer by opening the duodenum, closing the ulcer crater with deep sutures, and then closing the duodenum in way as to narrow it, finally making a gastroje He now, however, preferred gastrectomy for d ulcer. Before deciding at operation that bleeding due to gastritis, a most careful search must be for an ulcer, which sometimes might be very to find. If the search was finally negative, all arteries supplying the stomach were ligatured; even this would not stop the bleeding in every erosive gastritis, and when the bleeding from this was very severe gastrectomy should be done.

The early surgical treatment of gastroduodenal h rhage required that an experienced gastric surgeon continuously available, and there must be an enth team. Although they had improved their results they had undertaken more frequent surgery for rhage, he intended to revert for a time to selective intervention to see whether this improvement fortuitous. In any case there would remain one advantage in frequent surgery. When patients discharged on whom gastrectomy had been most of them were rid of their ulcer trouble for when they were discharged after a conservative many would return with bleeding and some would die

Mr. IVOR LEWIS thought that the managemen gastroduodenal hæmorrhage should be shared by physician and the surgeon, and the ideal combir was a keen young physician and a somewhat re surgeon. The surgeon should be careful to exch palpable tumour, an enlarged spleen, and a bl diathesis. Operation should be considered in all of peptic ulceration, aged over 40, with a h under 40%, especially if the bleeding was recurre persistent. It was difficult clinically to distin acute from chronic ulcers, and the preoperative diag could be expected to be correct in only about of cases. Frequent aspiration through a Ryle's was a good way of keeping a really close watch case, because the patient might not vomit the bloo collapse until an hour after the bleeding had st At operation the minimum requirements were to the bleeding vessel and to exclude it from the g juice. It was of fundamental importance to rec that bleeding from a peptic ulcer was seco hæmorrhage from a large vessel.

Mr. A. M. DESMOND described his experien St. James' Hospital with a series of cases of duodenal hæmorrhage; this included 45 cases peptic-ulcer group operated on with only 2 d In the selection of cases for operation, certain fe were unfavourable for medical treatment. Pa who had severe pain and vomiting before the bl started, those in whom the pain continued aft bleeding started, bleeding while the patient w hospital under treatment for peptic ulceration, an going through to the back, all suggested a serious nosis without operation. Emergency gastroscop of great help to a clear preoperative diagnosis.

Dr. AVERY JONES reviewed his experience i cases of gastroduodenal hæmorrhage with an o mortality in some years of between 6% and 7%. S had been used very little, but there was a small that did need operation: these were patients middle age who had repeated hæmorrhage. serious feature was the steady increase i average age of patients admitted with gastrodu hæmorrhage.

[illegible] Dr. DOUTHWAITE explained th as a serious feature b t stood the loss of blood

Mr. TANNER paid tribute to Dr. Avery Jones's adv of gastroscopy in hæmorrhage and said that i improved the rate of correct preoperative diagn St. James' Hospital from 65 to 85%.

For accurate and consistent CHOLECYSTOGRAPHY

The need for a standardized fat meal to promote evacuation of the gall bladder during cholecystography has been recognised. Fel-Evac has been found to meet this requirement satisfactorily. The use of Fel-Evac as a substitute for a meal of eggs with bacon or milk does not necessitate any departure from normal routine, but it does ensure that each patient receives a definite and known amount of fat.

Fel-Evac is so flavoured that patients find it quite palatable and it does not cause any discomfort. It is supplied in tubes containing sufficient for one dose and is prepared for use by simple mixing with water.

FEL-EVAC *A standardized fatty meal for Cholecystography*

Supplied in packages of 6 tubes, each tube containing 1¼ oz. (sufficient for 1 dose).

LONDON: SATURDAY, DEC. 17, 1949

Education and Practice

OGRESS has certainly been made in some of the tions indicated by the Goodenough Committee's rt in 1944. Contributing to a symposium on ical education,[1] Mr. L. FARRER-BROWN, who was etary of the committee, is able to show that ernment grants towards medical education have dily increased: in 1947–48 the medical schools ived from public funds about £2,500,000 more t before the war, and the promised figure for –52 is about £3,200,000, which will represent it £240 per student compared with the pre-war te of about £60. Though the committee has not red that all qualifying examinations shall be ternal" university examinations, its recomded abolition of the four remaining non-university lical schools has taken place. Its guidance has been largely followed over the appointment of f. There are now many more whole-time appointnts (senior, junior. and intermediate): whereas in 4. the undergraduate medical schools (excluding ord and Cambridge) had 11 whole-time clinical fessors, in 1948 they had 40, besides a few others were giving nearly all their time to their departnts in medical schools and teaching hospitals. ile the clinicians in charge of firms or clinics tinue to have full responsibility for the care of ients, they are expected to regard the professor ., of medicine or surgery) as the academic head of r department, responsible for the coördination of ching within the department and for its proper age with teaching in the other departments. In e schools, Mr. FARRER-BROWN says, the principle academic headship of departments has been cepted with reluctance and is not yet fully applied: t in the main it has been adopted more rapidly d widely than was generally expected five years ago. Advance can thus be recorded in what may be called e machinery of medical education. But are we yet ear on how the machinery should be used or even hat it is supposed to produce? Pointing out that me 60–75% of students become general practioners, Dr. P. J. MACLEOD agrees with the Goodnough Committee when it said that "the type of struction and the relative importance attached to various subjects should have a definite bias towards the needs of the future general practitioner." At present not only does the young doctor entering general practice find that he has to teach himself much of his difficult job. but he is wrongly oriented towards it: he probably feels guilty because he can no longer apply all the scientific methods possible in hospital. and because so much of his work is with the minor disorders which he has been taught to despise.

> "With such ill-preparation and with such an unpromising start," Dr. MACLEOD says, "it is a wonder how well most practitioners learn their work. Many don't. however. They leave off the scientific approach when they find it difficult or that it does not apply and take to the easy method of earning a living—sometimes with able tuition from a senior—by evasion, prevarication, and the glib tongue . . . The standard of medicine practised by some general practitioners is lower than that in any other profession and it is time the profession realised that fact."

Dr. J. H. F. BROTHERSTON argues that the real menace to the quality of practice today is neither the capitation fee nor the grossly inflated list of patients: "it is loss of a sense of pride in their work which seriously afflicts many men in general practice." For this the teachers bear some responsibility. During the student's impressionable years they may lead him to regard the social medicine of general practice as an inferior substitute for "real" medicine as practised in hospitals. And Dr. MACLEOD complains that later, when they meet him in general practice, they fail to realise that he has acquired knowledge which they lack. They are pleasantly condescending, and the practitioner, made freshly aware of his ignorance of a growing specialty, accepts the devaluation.

How is the student to get a proper training for general practice? Dr. BROTHERSTON rightly wants him to be taught some social medicine. "The gulf between hospital medicine and medicine outside is widening," he points out. "Yet the hospital remains the sole scene of medical training although there are many problems of individual and community health with which the hospital cannot deal." Dr. MACLEOD would like the student to see more of the beginnings of disease and have more practical experience in dealing with minor disorders: "most final year students can detail the stages of a gastroenterostomy but many of them have a very hazy idea only of how to incise a whitlow, or of what the drum looks like in an otitis media in a child." He would like every doctor after graduation to have a year's apprenticeship in practice; and this would at least ensure that the teachers of the future knew something about the work their students were going to do. Many believe that experienced general practitioners should give courses to students in their clinical years, either by coming into the teaching wards or by taking students with them on their rounds. The Cohen Committee[2] rejected both plans for what Prof. J. M. MACKINTOSH, editor of the symposium, describes as a "suspiciously large number of reasons."

Professor MACKINTOSH examines and contrasts the proposals of the Goodenough and Cohen Committees, from "premedical" education onwards. The Goodenough Committee thought that a good grounding in physics, chemistry, and biology at school should

The standard of medicine practised by some general practitioners is lower than that in any other profession and it is time the profession realised that fact."

Dr. J. H. F. Brotherston argues that the real menace to the quality of practice today is neither the capitation fee nor the grossly inflated list of patients: "it is loss of a sense of pride in their work which seriously afflicts many men in general practice." For this the teachers bear some responsibility. During the student's impressionable years they may lead him to regard the social medicine of general practice as an inferior substitute for "real" medicine as practised in hospitals. And Dr. Macleod complains that later, when they meet him in general practice, they fail to realise that he has acquired knowledge which they lack. They are pleasantly condescending, and the practitioner, made freshly aware of his ignorance of a growing specialty, accepts the devaluation.

How is the student to get a proper training for general practice? Dr. Brotherston rightly wants him to be taught some social medicine. "The gulf between hospital medicine and medicine outside is widening," he points out. "Yet the hospital remains the sole scene of medical training although there are many problems of individual and community health with which the hospital cannot deal." Dr. Macleod would like the student to see more of the beginnings of disease and have more practical experience in dealing with minor disorders: "most final year students can detail the stages of a gastroenterostomy but many of them have a very hazy idea only of how to incise a whitlow, or of what the drum looks like in an otitis media in a child." He would like every doctor after graduation to have a year's apprenticeship in practice; and this would at least ensure that the teachers of the future knew something about the work their students were going to do. Many believe that experienced general practitioners should give courses to students in their clinical years, either by coming into the teaching wards or by taking students with them on their rounds. The Cohen Committee[2] rejected both plans for what Prof. J. M. Mackintosh, editor of the symposium, describes as a "suspiciously large number of reasons."

Professor Mackintosh examines and contrasts the proposals of the Goodenough and Cohen Committees, from "premedical" education onwards. The Goodenough Committee thought that a good grounding in physics, chemistry, and biology at school should relieve the student of any detailed study of these subjects at the university; the Cohen Committee, on the other hand, held that this would cramp the student's general education, and that these pre-medical subjects should be used to give him a training in scientific method, which is best done in a university atmosphere. Both committees, however, see the student as an almost non-stop learner. The Cohen report does allow him eight weeks' holiday during each of the three clinical years, and short breaks at Christmas and Easter, but his preclinical studies are to be crowded into fifteen months, with fifty-six weeks of study—four of them, Professor MACKINTOSH remarks, "blatantly stolen from the summer vacation." Under the Goodenough plan vacation courses are held, which worthy students will attend to their physical and mental detriment, while "the gayer and more casual worker will reap an undeserved advantage."

[2] The Training of a Doctor. Report of the Medical Curriculum Committee of the British Medical Association, 1948.

> "The various committees have tended to regard the student too much in quantitative terms; they have been careful of his capacity as a holder-tank for learning. Or, in a more considerate way, the student has been regarded as an object whose health is to be promoted, who is to play games, and who is to be given the benefit of medical care when sick. All this is good, but the student is also a creature '. . . with such large discourse, looking before and after.' And each committee which reports on these matters has a plain duty to show how and when the student has time for eating, resting, reading, thinking, and playing. It would be nonsense to expect a timetable, but mere subtraction from a schedule of work is not good enough. The onus of showing time for other things rests on the committee that proposes a timetable of lectures and practical exercises. Here, for example, is a library—well-stocked, let us hope, for wide reading as well as for exact scientific reference; well lighted, comfortable, and spacious. When do the students have time (not merely snatched moments) to sit there, and read, and browse? At present they have far too little time to themselves, and even their spare evenings are clotted with hand-to-mouth medical fodder."

Dr. MACLEOD believes that the newly qualified doctor of today is a less developed man than his counterpart of a century ago, who had a larger experience of life and had learned his job in a more practical way: "the learning of an art gradually has been replaced by the rapid acquisition of a pseudo-science." The proposal in the draft Medical Bill (now awaiting Parliament's consideration), that a year of house-appointments before registration shall be compulsory for newly qualified doctors, will no doubt send them into practice better equipped, so far at least as hospital knowledge goes. But there is little sign that, even yet, the authorities have really come to grips with the question of what the student need not learn and why; and the curriculum, in prospect as well as in fact, remains ill-balanced, unwieldy, and poorly designed for its purpose. The contemporary student may be excused for feeling that between the various millstones he is being ground exceeding small, and it can be no satisfaction to him to know that having gone through the mill he will emerge only half-baked. As Professor MACKINTOSH says in conclusion, "it is pathetic to see that all committees demand . . . of candidates for medicine the very qualities which they are industriously stifling in the overcrowding of the medical curriculum—broad and humane qualities which will make the student a better doctor and a better citizen."

Tuberculous Patients' Washing

ng. Some years ago the Registrar-General,[2] aching the problem from another direction. ed that in male laundry workers the standard ality-ratio from tuberculosis is low (70) and that omen over thirty-four it is not significantly high but that in young women below that age it es 151; so the possibility of infection from lry handling cannot be ruled out. There ars, in fact, to be good grounds for a new and ugh bacteriological research into the mode of mission of the human strain of tubercle bacillus. of existing knowledge is inadequate and is l on early unreliable experiments. Meanwhile ospitals and sanatoria the possibility that tion may be distributed via the patient's night- es should be considered; for we are not justified glecting any simple precaution. On occasion the ma jacket and the front of the nightgown may carry a heavy load of infection. The waking nt reclining in bed normally has his arms outside coverlet, with the bedclothes drawn up to about nipple line. When he coughs, then, the front of nightwear is as liable as the bedclothes to receive ay of micro-organisms. This garment is later rolled and handed to the relative, who often tucks it the family shopping bag. When she gets it home may stuff it into the family clothes basket: or e it rolled up on the kitchen table while she cuts bread for tea: or shake it out—possibly over family butter and jam—to see whether it needs ding; or stop to rub the baby's sore gums with finger while she is in the act of darning it: or ny number of other natural but unhygienic things ch may introduce risk. Some hospitals warn of these risks: most it seems do not. Some see t the washing is handed over to her in a paper and give her a printed list of directions about hing it: some give her no advice at all. So far ur knowledge goes, no hospital at present arranges terilise such clothing before it leaves the premises. it would surely not be difficult to provide calico s, marked with the patient's name, which would e all his soiled linen, and which could go through autoclave once a week, on the eve of visiting- . This measure would presumably end the s at one stroke: but if for some reason it is of the question the clothing should be handed r in strong paper containers, and relatives should given some simple rules for dealing with it.

High Thoracic Œsophagectomy

THE rapid development of the surgery of œsophageal er in the last ten years has been bound up with o measures: free transpleural resection, and imme- ate restoration of continuity. This phase dates om ADAMS and PHEMISTER's[3] operation of 1938, hich became the standard procedure for cancer of e cardia. This involved left thoracotomy, trans- renic resection of the growth, and mobilisation of e stomach, bringing up the remainder thereof to e anastomosed to the œsophageal stump. Recently urgeons have improved the approach in this opera- ion, by adopting an abdominothoracic incision such s was used by the Japanese surgeon OHSAWA in 1933. The technical problem of growths of the middle third was solved five years later, in America by SWEET,[4] using a left thoracotomy and a supra-aortic anastomosis, and in this country by IVOR LEWIS,[5] who favoured the approach through the right pleura and a separate epigastric incision. Both these surgeons pointed out that the stomach, carefully mobilised, would reach the dome of the pleura, allowing a high anastomosis free from tension. Thus it came about that the Torek œsophagectomy, never satisfactory as a palliative operation, was almost given up. But this must be said for the Torek operation: it did not tempt the surgeon to conserve more than he should of the proximal œsophagus—a sin often committed by the anastomers-at-all-cost.

Growths of the cervical œsophagus are mostly postcricoid, and these have been treated on different lines. As long ago as 1886 MIKULICZ reported a case of postcricoid carcinoma where he had not only done a resection but had successfully restored continuity by means of a skin tube. This method was later perfected by TROTTER, but its general adoption was checked by the advent of radiotherapy, which is effective in many of these comparatively superficial growths. There remains, however, a stretch of œsophagus in the thoracic inlet and the superior mediastinum—from about an inch above the manubrium to the angle of Ludwig—where it seemed that these two principles of modern œsophagectomy were impossible to apply. This no-man's-land lies opposite the 1st, 2nd, 3rd, and 4th dorsal vertebræ. Fortunately these growths above the aortic arch are uncommon. A Torek operation, even if desirable, is difficult owing to the shortness of the œsophageal stump. "The difficult we do at once: the impossible may take a little longer." It was obviously only a matter of time before the boldness of the surgeons, combined with what may be called the far-reaching qualities of the stomach, solved this problem too. Both SWEET[6] and GARLOCK[7] reported cases in 1948 in which they had been able to resect such a growth, bring the stomach the whole way through the thorax into the neck, and there anastomose the fundus to the stump of the œsophagus. Several other successes with this procedure have been reported since—by WYLIE and FRAZELL,[8] LYMAN BREWER,[9] and RUDOLPH NISSEN[10] in carcinoma; by SWEET[11] in a case of congenital atresia; and by TAYLOR and CLAGETT[12] of the Mayo Clinic in a boy with lye strictures. Besides the awkwardness of the approach to this region, which is reasonably accessible neither from the neck nor from the thorax, there is also the problem of the restoration of alimentary continuity which has baffled generations of surgeons. The great number of techniques described for the construction of an antethoracic gullet is eloquent testimony to their difficulty and uncertainty. The anatomical difficulties are enhanced by the fact that the thoracic inlet is tightly packed with important structures leaving little room to spare within its bony ring. Two elusive but important structures which are hardly ever injured in œsophagectomy lower down are the thoracic duct and recurrent nerves. In resection of growths, unnoticed division of the duct or damage to both recurrent nerves is likely to prove fatal. At this level the vagus trunks must also be respected.

The steps of the operation, say for a growth at the level of D2, opposite the jugular notch, are three. It is a good plan to begin by exploring the neck through a long incision along the anterior margin of the left sternomastoid, continued for an inch or more down the front of the manubrium. The œsophagus is isolated and the finger passed down into the thorax between it and the longus colli. If the growth is found to be operable, the inner third of the clavicle and anterior half of the first rib are resected. The patient is then turned on his right side and re-draped for the second stage. A left thoracotomy is done. The diaphragm is divided and the stomach mobilised, carefully preserving the right gastric and right gastro-epiploic vessels. The left gastric branches are divided close to the stomach. This allows the stomach to stretch into a long straight tube. The œsophagus is cut off at its lower end and the cardia is closed. The second part of the duodenum is mobilised. It will now be found that the antrum will come up to the diaphragm and the fundus of the stomach reach the dome of the pleura. The arch of the aorta is mobilised, and the œsophagus, with its growth, is freed and passed up through the cervical wound. The fundus of the stomach is fastened just below the dome of the pleura so as to be readily secured from above. The chest is then closed and the patient again placed on his back for stage three. The neck wound is opened. The thoracic œsophagus is delivered and the fundus of the stomach brought up into the neck and secured to the prevertebral fascia. The œsophagus is resected, and an end-to-side œsophagogastrostomy done just below the cricoid. The following are important: to preserve the cricopharyngeus; to avoid damage to recurrent nerves and thoracic duct; judiciously to divide the left gastric branches so as to allow maximum stretching of the stomach while yet not devascularising any area of the fundus; and, finally, so to place the sutures in the prevertebral fascia that they hitch the stomach well up and prevent any pull on the anastomosis itself. Postoperatively, trouble may be expected from shock, bronchi [illegible] and regurgitation of food. In some cases [illegible] has caused attacks of coughing and cyanosis—doubtless due to postoperative œdema of the stomach incarcerated in the neck—and it seems sounder always to remove lengths of rib and clavicle.

These resections are undertakings of great magnitude, bound to have a considerable mortality. The operation time in one of the cases reported was $6\frac{1}{2}$ hours, and in another $9\frac{1}{2}$ hours. With regard to the operation itself, it may well be that the right pleural route would be better than the left, though needing three incisions. The indications for the procedure are cancer, and possibly some cases of benign stricture. With regard to the cancers several considerations arise. Postcricoid carcinoma should be treated either by radiotherapy or by resection with local œsophagoplasty—a method recently revived by Wookey. Cervical œsophagogastrostomy should not be done for these; it is more hazardous and no more radical than local resection, and it is unsatisfactory if the pharyngeus is not preserved, for peptic ulcer occur not only on the stoma but on the pha wall. Postcricoid carcinoma lies opposite C6. C at the level of C7 also will not allow an margin above if the pharyngeal pinchcock is to preserved. For some of these growths—especi really operable early ones—the pedicled ski operation suggested by Bricker et al.[13] may be answer. Their plan has the advantage that surgeon's energies at the first operation are trated on the thorough dissection of the area. It must not be forgotten however that growths may respond to radiotherapy, and where is the case the result is likely to be at least as good that of a limited dissection by the surgeon. The of this procedure for simple strictures requi consideration. In the first place, it is difficult disciples of Chevalier Jackson or of Grey T to believe that there are many simple strictures will not finally respond to skill and patience in tion. Time does not press and so the various me of antethoracic œsophagoplasty have a place—notabl the jejunal method of Yudin. The use of jejunu with or without a skin bridge would seem a sound undertaking for the few simple strictures whic cannot be satisfactorily dilated. In simple strictu the cervical œsophagogastrostomy enthusiast mu show that the operation can be done with reasonabl risk. He still has to convince us that it was reall necessary, and that, having been done, it is satisfactory

Annotations

RESUSCITATION IN RESPIRATORY ARREST

Sooner or later most practising doctors are fac with a case of respiratory arrest, or "respiro-cardi crisis,"[14] in which the patient's life depends on ho quickly proper treatment is applied. These cases a by no means limited to the operating-theatre and th orbit of the anæsthetist; so diverse are the causes o asphyxia that the patient requiring immediate resuscita tion may be a newborn baby in the delivery-room, housewife in her home, a workman in the factory, child on the river-bank, or a motorist in his garage o on the roads. In the United States a group of physician anæsthetists, and others have formed a Society for th Prevention of Asphyxial Deaths,[15] to disseminate kno ledge of the hazards and treatment of asphyxia. Th it is apparently not uncommon for laymen, such as police or the fire force, to be called on when resuscita is needed, rather than a medical man, even when th patient is inside a hospital. Such a practice may b unknown in England, but that there is a need here to for education in the prevention and treatment of the emergencies has been convincingly shown by Macintosh. He describes with welcome bluntness and clarity th number and variety of circumstances in which lives a needlessly lost in connexion with anæsthesia alon His article is a challenge to teachers of anæsthetics an hospital administrators, for nearly all the deaths a due to [illegible] during the administratio [illegible] are in the recovery perio of an a[illegible] Professor Macintosh's advice should be studied by eve newly qualified doctor before starting his first hous appointment.

ion of Asphyxial Deaths, hopes to make every doctor
se that impending asphyxial death is "the supreme
of his life-saving skill as a physician."

HE RH HAPTEN AND ERYTHROBLASTOSIS

RECENT number of an American advertising
al, *What's New*[21] carried an article on the "Rh
en," and suggested that this substance, or some
ance with the properties of Rh hapten, had been
ined in a form suitable for clinical trial. In theory
hapten is that part of the immune body which,
her with complement, combines with the immune
ody and neutralises the properties of the antibody.
it has been known that erythroblastosis of infants
e to the presence in the maternal blood of anti-
es to factor Rh, it has been clear that if the appro-
e hapten could be obtained it could be used to remove
maternal antibody, and so perhaps prevent the
lopment of this hæmolytic disease of the newborn.
action of Rh antigen and hapten from erythrocyte
na was reported by Calvin et al.[22] early in 1946.
claimed that the Rh antigen was a lipoprotein
ined in the elinin portion of stroma extract. From
fraction they obtained an ether-soluble material
a higher content of Rh-inhibitory activity than the
nt substance, or the original red-cell stroma. In
Carter[23] reported that from an ether extract of
ositive red blood-cells she had prepared a crude
rial that would neutralise Rh antibody in vitro
was presumably Rh hapten. Price et al.[24] confirmed this report and stated that they had purified this crude extract and obtained a crystalline material which, when tested by complement-fixation with anti-D serum, was active in a dilution of 1 in 5000. Further purification, however, suggested that at least two different substances were present, possibly corresponding to different Rh subgroups. Later Carter[25] described a revised technique for preparing this Rh hapten and gave some details of clinical trials.

Carter started off with a large volume of pooled human red cells of any ABO group and comprising as many of the Rh subgroups as possible, except for Rh-negative (cde/cde) cells. After various chemical manipulations, a lipid substance was obtained that would inhibit Rh antibody in vitro and would fix complement in the presence of Rh antibody. Guineapigs were injected with Rh-positive cells and Rh antibodies appeared in their blood: when the hapten material was injected into these immunised guineapigs, a fall in the titre of Rh antibody occurred, and this fall was used as a rough assay of the activity of the hapten lipid. Methods were described for in-vitro assay of the hapten activity of the material that were claimed to be more accurate, and no difficulties with non-specific reactions were encountered. As expected, no substance with hapten activity could be prepared from Rh-negative (cde/cde) red blood-cells. The material was said to be relatively stable—it kept without deterioration for at least three months at room temperature—and so was readily available for clinical trial.

For clinical use, 100 mg. of the preparation was dissolved in 1 ml. of alcohol, suspended in 10 ml. sterile saline, and injected intramuscularly; no untoward reactions occurred. The material has been given in this manner to thirty women. Eight mothers with Rh antibodies present in their blood delivered completely normal babies, and in two cases the infants had mild erythroblastosis. Seven mothers were not delivered at the time of the report, but the titre of Rh antibodies in their serum had been reduced. Four children were lost; two were premature and did not survive, two died in utero; in these four mothers treatment was begun late. In eight further cases reports were incomplete, and in the remaining patient an attempt was being made to reduce the Rh antibody titre before a further pregnancy commenced. Loughrey and Carter[26] and others have tried the preparation for the treatment of infants affected with erythroblastosis. Twenty-seven infants were treated; twenty recovered and became normal and well, seven died—but in five of these death was due to some other complication. Of the twenty recoveries, only six needed blood-transfusion, and then a single transfusion of 100 ml. of whole blood sufficed. These results were obtained in clinically severe cases; if it was thought that the infant would recover spontaneously this form of treatment was not given.

Now it is known to all workers in this field that the preparation of an Rh hapten might well solve the problem of how to prevent the birth of an infant affected with erythroblastosis when the mother is known to have Rh antibodies present in the blood; and equally, it might be used for the treatment of the erythroblastosis in the infants themselves. Present methods of dealing with these syndromes are not very satisfactory and alternatives would be welcomed. The successful preparation of Rh hapten suitable for clinical use would therefore be news indeed. But, though the first announcement of the extraction of an Rh hapten was made in 1946, no confirmation of the claims of Carter and her colleagues has yet appeared. Mrs. Carter herself says of the clinical reports: "it is imperative that great conservatism

be the state of mind when approaching this phase of the problem," and it has to be remembered that there are probably other factors, besides maternal sensitisation, that influence the prognosis of erythroblastosis. This silence is undoubtedly due to difficulties that have arisen in repeating Mrs. Carter's results. The chemical techniques used by her produce a mixture of blood lipids, and it may well be that substances that inhibit Rh agglutination are contained in this mixture; but that these extracts represent Rh hapten in a reasonably pure form seems unlikely. In view of its importance, we hope that those who have been trying to repeat Carter's work will soon publish their results, positive or negative. Meanwhile the treatment of erythroblastosis in infants must follow present lines.

TEMPORAL ARTERITIS

FIVE further examples of the condition now known as temporal arteritis have lately been described by Migone and Mortara[1] in Italy. The pattern of the disease ran true to type. During the prodromal phase, which may last from a few days to many months, the patient feels unwell and usually has a fever ranging between 99° and 103°F, joint pains, pains in the muscles, often with well-marked tenderness, night sweats, lassitude, and anorexia—a vague pyrexial illness with no obvious localising feature or characteristic change in the blood-count or blood picture to aid in diagnosis. In most patients the general symptoms are sooner or later overshadowed by more definite disturbances of special systems.

Headache, of a particularly severe and continuous type, is almost invariably present. It may be generalised or confined to the occipital or frontal regions. Its severity may be judged by the frequent necessity of large doses of morphine, which give only temporary relief. At this stage the temporal artery is felt as a thickened tender tortuous cord, and the overlying skin is reddened. Ocular and oculomotor manifestations were met with in 55% of the 121 cases analysed by Migone and Mortara. Direct spread from the temporal artery to the arteries of the optic nerve has been postulated as the basis for this high incidence, but Migone and Mortara prefer to ascribe the ocular complications to systemic dissemination. The visual disturbances range from blurring of the field of vision to actual blindness, which has occurred in 30 to 50% of reported cases. The oculomotor symptoms include transitory ptoses, dilatation of one pupil, or strabismus. Cerebral disturbances are frequent and are easily misconstrued. There may be hallucinations or transient disorientation, and delirium, sometimes leading rapidly to coma, may also occur. In patients in the sixth or seventh decades these may be dismissed as secondary to the general systemic disturbances and cerebral arteriosclerosis. It would therefore be wise to consider temporal arteritis as a possible diagnosis in any elderly patient with central nervous symptoms, especially when these are accompanied or preceded by a pyrexial phase. Coronary thrombosis or angina pectoris have been included in the symptom complex, and Kaye[2] has described in detail the onset of pericarditis with characteristic electrocardiograph changes during the pyrexial stage.

The Italian workers managed to obtain biopsy specimens of the temporal arteries in most of their patients. Their findings confirm those already accepted, though there is still dispute as to the exact site of the disease process in the arterial wall. They postulate a panarteritis, suggesting that it is difficult to prove that any particular coat bears the main brunt of the infection. Cooke suggest that the process starts subacutely in adventitia, spreading to involve the media and intima. Andersen[4] thinks that the initial lesion is tunica intima, and is proliferative in nature, the coats showing an exudative or chronic reaction with giant-cell formation. Certainly cells are commonly found, and in fact are said characteristic. The ætiology is still obscure. and Mortara could not identify any specific ætio agent in their cases, and this has been the c of other workers, even after the most exhaustive logical and cultural tests. Gordon and Thurber[5] that histologically periarteritis nodosa and te arteritis are identical, but this view has been di by Harrison.[6] The responses of the arterial injury, whether this is allergic or bacterial in are of course limited; so similarities in the path changes present in the two conditions do not sarily prove that a similar agency is responsible fo Biochemical tests of the plasma-protein level constant relative hypoalbuminæmia. The actual protein level may not be altered, for the plasma is correspondingly raised.[7] The significance change has not been explained, though it might for the raised erythrocyte-sedimentation rate w always present in the disease.

Temporal arteritis thus remains a clinical syndr unknown ætiology. The pathological changes are constant, though the histological picture seen in specimens will depend on the severity of the the site from which the specimen was taken, a stage the disease had reached at the time. The be little doubt that temporal arteritis is only a p larly prominent manifestation of a general disea one which may involve the veins and the a simultaneously or successively.

MECHANICAL HEART SOUNDS

A DEVICE for demonstrating heart sounds to st recently described by O'Farrell,[8] produces the artificially and synchronises them with an illum diagrammatic model of the heart cycle. It is c that "the construction and components of the app are simple and can be assembled in a well-equipped service station." The apparatus has the advantage of being readily portable. The two sounds are produced by two hinged metal ha striking separate drums, and murmurs are evok the friction of a smooth metal edge on fibro (e.g., bicycle brake-block). The murmurs are mitted separately to a narrow plank of wood c with cotton-wool and velveteen, to which the li students apply their stethoscopes. The visual consists of five mounted flash-lamp bulbs enclo boxes faced with coloured glass and marked sound," "second sound," and "presystolic," "sys and "diastolic" murmurs. These sound box "suitably placed over the 'murmur' boxes so indicate the interval between the sounds in the ventional graphic manner." Ten different combin of sounds can be produced.

This ingenious machine is said to be helpful t student with little clinical experience while he is stu pathological specimens of the heart, and also a next stage when he first starts using a stethosco hospital. Physiologists might find it useful in teaching of preclinical students.

Points of View

RMY MEDICINE IN THE LATE WAR

SOME MISTAKES OF POLICY?

JOHN W. TODD
M.D. Lond., M.R.C.P.
ISTANT PHYSICIAN TO FARNHAM HOSPITAL; LATE
LIEUT.-COLONEL, R.A.M.C., OFFICER IN
CHARGE OF MEDICAL DIVISION

1. Malaria

ny campaigns during the war, and particularly rma, malaria had a profound influence on the ions. According to Marriott (1945), the admission-o medical units serving the Burma Front was, in just under 1200 per 1000 troops per annum, and proportion of these casualties—up to 80% during d seasons of the year—were caused by malaria.

PREVENTION

best method of malaria control—destruction of sect vectors—was clearly inapplicable to the zones tual fighting. An infantry attack could not be led by the advance of a large anti-malaria squad ing D.D.T. and draining pools. Even in the base with the possible exception of certain large towns ld-standing military encampments, this method, h widely used, was only partially successful.

e military authorities, especially during the first ears of the campaign, pinned their faith largely to ndividual efforts of the soldier to prevent himself being bitten by mosquitoes. There were strict s that everyone should invariably sleep under squito-net, which should be put down before dusk, hat long sleeves and long trousers should always be during the hours of darkness. Every soldier was d—or should have been issued—with a tin or bottle osquito repellent, which he was ordered to smear l exposed parts of his person at two-hourly intervals dusk when not under a mosquito-net. Even the istance of the soldier being compelled to leave his y the call of nature was not overlooked: before g the net he was ordered to smear with repellent his ks and other parts which would be exposed.

t in spite of much propaganda these orders were ly ignored. The majority of soldiers doubtless slept arly under mosquito-nets, unless they were in the of the enemy, when this was impracticable. They kept their sleeves rolled down when under the eye of ority. But few attempts were made to enforce the hourly smearing with repellent: I was never in it in which this rule was observed. And there were soldiers who did not, when alone or in the company iends, habitually expose unanointed parts of their s after dusk. This slackness was common to all s and to all branches of the Service.

was argued by those responsible for malaria policy these widespread breaches of anti-malaria dis-e were a scandalous reflection on soldiers in general officers in particular, and that malaria would be vented only if the precautions were observed. But reasoning is futile. If regulations are so onerous t they are widely ignored in spite of intense efforts, blame should fall on the framers of the regulations, on those who have to carry them out. Even if every dier had obeyed his orders in respect of mosquito-e prevention to the letter, it seems highly doubtful ether the incidence of malaria would have been sensibly inished: for when mosquitoes are really numerous few bites are inevitable. This conclusion applies rticularly to front-line soldiers, who were preoccupied th the enemy and commonly had to fight in intensely alarious areas.

Prophylactic Mepacrine.—Though the Burma campaign began in 1942 with the Japanese advance to the frontiers of India, it was not until 1944 that mepacrine was continuously administered to troops, and some of the personnel of units in malarious areas did not have it till 1945. For generations a daily dose of quinine has been taken by many Europeans living in malarious countries, with the conviction that thereby malaria can be suppressed. Mepacrine was discovered in 1930 and its efficacy as a curative drug was soon demonstrated beyond question. Quinine supplies being largely cut off by the Japanese occupation of Java it must be wondered why prophylactic mepacrine was not introduced sooner in Burma.

DIAGNOSIS

From early in 1943 until the end of the war in Burma the methods of dealing with malaria were largely laid down by regulation. Perhaps the order which had the most far-reaching consequences was: "*every effort will be made to establish diagnosis by microscopic demonstration of malaria parasites before treatment is begun.*" This statement was qualified by such further statements as "this must not be allowed to delay urgently needed treatment," but it nevertheless appeared at the beginning of every edition of the regulations about malaria treatment, even after suppressive mepacrine (which, if malaria develops, increases the difficulties of finding the parasites) had come into general use. It was also stated that "*all attempts at microscopic diagnosis having failed,* should the clinical condition justify a diagnosis, treatment must not be withheld" (my italics).

Since regimental M.O.s were not provided with microscopes, this order, if obeyed, meant that every soldier with suspected malaria had to be admitted to a medical unit. Not only, therefore, were fighting soldiers in the face of the enemy evacuated (which may seem reasonable) but the sepoy in an I.E.M.E. maintenance unit alongside the Manipur Road and hundreds of miles from the nearest Jap, who had what seemed a typical malarial attack, could not just be given quinine or mepacrine, but instead had to go to a medical unit perhaps fifty or more miles away: and this meant that his unit might not see him again for weeks. (The same sepoy in his native village would, when ill with malaria, merely lie down for an hour or two and then proceed with tilling the land and have no further fever for a long time, owing to the immunity acquired by the repeated infections he suffered throughout life.)

A second consequence of the order was that the initiation of treatment was always delayed a little and often delayed for a long time. Many soldiers had several rigors, with all the unpleasant symptoms accompanying them, before they received drugs: and of those infected by virulent strains of *Plasmodium falciparum* no doubt a few died.

In December, 1944, when stationed with an Indian malaria forward treatment unit in the Kabaw valley, I made a special study of all the suspect malaria cases among the British other ranks who were patients at one particular time. Of sixty-nine cases, twenty-one had remained untreated (apart from the statutory mepacrine tablet daily) for 3–7 days before being admitted to the unit. This time had chiefly been spent in a main dressing-station, where repeated blood slides had been examined. The men were not very ill, and, as the evident result of their small daily dose of mepacrine, had only moderate degrees of fever. They all quickly recovered when given quinine and mepacrine in adequate quantities.

It must be wondered, then, why this order was ever made. The usual defence was that to treat patients before the diagnosis was certain was "unscientific." But even admitting this, it is not true that the finding of parasites in the blood-stream is always the best way to diagnose malaria. On the contrary, in the case of Indians and Africans (who together formed the great majority of the troops in Burma) the presence of malaria parasites by no means proved that their fever was malarial, for most members of those races have had malaria throughout their lives, and the parasites can commonly be found in their blood when they feel perfectly well. Even among British troops the presence of parasites did not prove that they had malaria alone. And the failure to find parasites, especially among British troops who had not previously had malaria, could not, by universal agreement, exclude the disease. On the other hand, a single brief high fever, preceded and followed by afebrile periods, could hardly be due to anything but malaria, and such fever occurring every second or third day provides evidence as near pathognomonic as any in the whole field of medicine. Here, indeed, is a good example of the extraordinary assumption, so commonly made now in the medical world, that the evidence of the laboratory is inevitably superior to the clinical evidence.

And the premise that there is something wrong or "unscientific" in giving treatment before the diagnosis is made is itself damnable. Diagnosis is not an end in itself but the means to an end. To give quinine or mepacrine to those who in fact are free of malaria cannot do them any possible harm, and to give the drugs as soon as the disease is suspect can only do good.

A further defence of the order was that if soldiers were wrongly started on anti-malaria treatment, they would unnecessarily be held in hospital, since the official scheme of treatment, until February, 1945, lasted 2 weeks. But this implied that it was in fact correct automatically to keep soldiers in hospital because they had had a malarial attack—a question to which I shall return.

A comparison between this order and a number of orders issued in connexion with certain other diseases is interesting. Thus, a memorandum of August, 1944, about scrub-typhus, said: "If a suspected or definite typhus case has come from a malarious area he must forthwith be given a full course of anti-malarial treatment *whether or not malarial parasites are found in his blood-stream.* Neglect of this precaution has resulted in deaths . . ." (my italics). In other memoranda it was laid down that all soldiers who had been wounded, who were admitted to hospital for ordinary surgical operations, or who had severe anæmia should be given anti-malaria treatment. Thus if a medical officer had the best clinical evidence for supposing that a man had malaria he was strongly discouraged from prescribing anti-malaria remedies; but if he knew that a man had one of these other conditions he was *compelled* to prescribe these remedies!

It was not surprising that this order was widely ignored. In many units officers and N.C.O.s were not evacuated when their regimental M.O. thought they had malaria, but were given quinine and mepacrine on the spot, even though the rank and file were disposed of through the correct channels.

A company commander of a field ambulance who had been in the 36th Division during the advance from Myitkina told me that of course his own personnel who developed malaria did not become casualties as they should have done. They were immediately given the drugs and as soon as their fever had subsided returned to duty. "If we had done otherwise," he said, "the unit would have become incapable of functioning and the evacuation arrangements would have broken down completely."

The commanding officer of an infantry battalion told me that when his unit was on the Arakan Front it acquired great prestige because of the almost complete absence of malaria among its personnel. In fact there were many cases of malaria, but they were kept in a special tent, having the drugs until their fever subsided; they then returned to duty. This policy was continued even when parts of the battalion were in contact with the enemy. On the occasion of visits by an A.D.M.S. or D.D.M.S., the malaria tent was struck and the casualties were hidden in the jungle, all evidence of being thus obliterated.

In such ways as these did individuals and in units diminish, if only slightly, the disastrous this order.

TREATMENT

Until February, 1945, it was laid down that all of malaria should be given the following course of ment: Days 1 and 2, quinine gr. 10 t.d.s.; days mepacrine 0·1 g. t.d.s.; days 8 and 9, no drugs; 10 to 14 pamaquin 0·01 g. t.d.s. (After February, a course of mepacrine only, lasting 7 days, was instit Now it was officially decreed that pamaquin was a drug, and an order was issued that all those tal must be kept at rest. Since it was given at the end course, fighting soldiers could hardly be sent st back to duty even two weeks after beginning their ment. It was customary in many medical units to them for a further week or two. A Fourteenth operational research group, investigating a sam soldiers admitted to a casualty-clearing station Kabaw valley during October, 1944, found th average time spent there by Indian other ranks on a of malaria was 23·5 days.

Pamaquin was apparently prescribed for two re first, to destroy the gametocytes and thereby di the number of infective mosquitoes; and seco hinder relapses. But the vast reservoir of native p tions took neither pamaquin nor anti-mosquito cautions, which disposes of the first reason. And t pamaquin may have a slight effect on hindering re this could not possibly counterbalance its adverse e immobilising vast numbers of men in hospital. Mo the use of pamaquin was for about a year comp even for troops having suppressive mepacrine (w an immeasurably more effective way of prev relapses). It commonly happened that soldiers n relapsed while having pamaquin. In this event medical officers who obeyed orders began the 14-day course again, with the chance of their p relapsing once more when taking pamaquin f second time.

After the "mepacrine only" course was insti the average stay in hospital of malaria cases do decreased very considerably. Nevertheless, it was to retain men for the full 7 days at least, and in units for considerably longer. Admittedly, no ord issued insisting on this, but no order was issued enc ing the practice of discharging men while still treatment.

CONSEQUENCES OF THE OFFICIAL POLICY

When a soldier belonging to a static unit in a area entered hospital with malaria, he could be ret straight to his unit as soon as his course of treatmen over. He was a casualty, therefore, for only 2 weeks. But the soldier who fell ill near the Fron to be evacuated for a considerable distance; s problem arose of returning him to his unit whe charged. The fact that as a rule the Front was cons fluid, changing its position perhaps by many miles day, further aggravated the difficulties. Durin earlier phases of the campaign the flood of malaria was so great, in relation to the number of forward that the orders making it inevitable for all men wi disease to remain in hospital for over 2 weeks repeated evacuations from hospital to hospital, farther away from the fighting zone. In 1943 man who developed malaria in the Arakan did not come to rest until they had reached such plac Bangalore and Rawalpindi, thousands of miles There was naturally a very long interval before suc arrived back at the Front again. Statistics as t average time malaria cases remained hors-de-comb itly unavailable, but during that year the figure ave been several months. Even when there were it Indian malaria forward treatment units in the l areas to deal with every case of malaria, a soldier harge might often be some hundreds of miles from n position of his own unit. As a rule his immediate tion was the nearest transit camp, where he would until a plane or truck took him forward. The ent in transit camps was commonly measured in or months rather than days.

ever short the period spent in hospital, and r efficient the machinery for returning men to nits, if soldiers were once evacuated there was during the mobile phases of the war in Burma, a long interval before they reached the Front The only way of avoiding this wastage was to en in their units; and if they developed malaria uld only be done by disobeying orders.

DISCUSSION

peans long resident in malarious countries, and e few well-to-do natives of those countries, have erations dealt with malaria very simply. On the mptoms of what they believe is an attack, they iately start a course of quinine. The hardier, ose with the mildest attacks, then continue with ork or play. For a worse attack they may retire with a bottle of whisky, a bottle of aspirins, and water bottle, and perhaps remain there for a few returning to work the following morning. If still next day they may summon the doctor, and y go into hospital for a few days. When such men the Army, they were astounded to discover that case of malaria was admitted to a medical unit eks.

e is nothing original, therefore, in suggesting oldiers with malaria should have been managed similar lines. Regimental M.O.s should have been instructions that whenever a soldier seemed to malaria, the exhibition of anti-malaria remedies commence immediately. Whenever practicable uld not be evacuated but retained in the unit. provided his fever had gone by next day, he return to his ordinary duties if he seemed well, not, to light duties for a day or two. Only if the persisted should he be evacuated.

h a scheme would not, perhaps, have been always able to troops in contact with the enemy, unless ymptoms were unusually trivial. But at any one he number of troops actually fighting was usually small; a high proportion even of the infantry not in action, while there were vast numbers of of communication troops who were never, except ident, near the Front.

y the authorities did not adopt a scheme along lines I was in no position to judge; but it is possible nk of various reasons.

t may be argued that soldiers live lives so arduous mparison with civilians that though it may be reasonable for the latter to return to work immey after they become afebrile for the first time rs require a further period before they are "fit" In fact a high proportion of soldiers do not as e live particularly arduous lives; and even infantrymay not do so for long periods at a time. Moreover, attacks of relapsing B.T. malaria (which formed the st proportion of the cases) if treated immediately o trivial that their victims seem perfectly well in y way within a very short time.

In the Army there is a tendency to regulate as h as possible by fixed drills designed to cover all ingencies. Now malaria in its M.T. form can be a most us, even fatal, disease; and those who are very ill it should obviously not be retained in their units. Therefore, since some should rightly be admitted to hospital, a rule making it inevitable that everyone should be so treated naturally follows. In a similar manner, since some soldiers should be in a high state of "fitness," a rule is made requiring that all should be in this same state. But admitting all that may be said in defence of this Army practice, any attempt to make fixed regulations for a disease so variable as malaria, affecting soldiers whose conditions of life differ so widely, is surely unjustified.

3. There might be parliamentary or press criticism if it was alleged that soldiers were sent back to duty too soon after attacks of malaria.

4. If soldiers were treated in the field by their regimental M.O.s, there could be no guarantee that they would receive their drugs regularly. This argument has some substance. Nevertheless, to ensure that all soldiers being treated for malaria attend a parade once daily (for the drugs could satisfactorily be given in a single dose) should rarely have been difficult, especially after the use of suppressive mepacrine became compulsory, for then everyone had to attend a daily parade for his tablet. And this procedure was certainly far more easy to carry out consistently than were the complex and irritating anti-malaria regulations which were officially compulsory for all.

5. Regimental M.O.s might misdiagnose other fevers as malaria. This may be so, but it would soon have become apparent that a diagnostic error had been made; and if the cases were then evacuated (perhaps one or two days after the start of their illness) it is most unlikely that harm would have been done.

6. If malaria were diagnosed clinically, the statistics as to the ætiology of fevers would have been wrong. But this assumes the wrong premise previously discussed—that the laboratory diagnosis of malaria is inevitably superior to the clinical. Moreover, many cases of malaria diagnosed clinically were deliberately given such labels as dengue or sandfly fever, because it was thought that Authority disliked the diagnosis "clinical malaria."

CONCLUSION

I believe the schemes for preventing and treating malaria in the Burma campaign were mistaken. It is widely supposed that, though at first malaria was a more serious enemy than the Japanese, in the end the tremendous efforts of the authorities, scotched, if they did not quite destroy, this enemy. The arguments here advanced suggest that, on the contrary, the delay in introducing suppressive mepacrine, the discouragement of the early exhibition of anti-malaria drugs, and the insistence on prolonged hospital care for each malaria case contributed to disastrous happenings in 1943 and 1944; and that suppressive mepacrine, the shorter hospitalisation, and the increase in forward medical units made the situation later not quite so bad. The regulation urging that soldiers should not be treated for malaria on clinical grounds was, I believe, particularly unsound.

2. Amœbiasis

NEXT to malaria, amœbiasis was probably the most serious medical problem in Burma. It was much less common than bacillary dysentery, but it was a greater menace because that disease is as a rule trivial and of short duration. According to Marriott (1945) it was "the most important single cause of protracted illness and invaliding" from the Burma theatre.

Amœbiasis is similar to malaria in its susceptibility to specific drugs and its tendency to relapse. But it does not consistently and rapidly respond to treatment in the same manner. And whereas the relapses of malaria tend to be both less serious and more susceptible to drugs than the first attack, the relapses of amœbiasis are usually worse and less susceptible. Commonly the and Africans (who together formed the great majority of *the troops in Burma) the presence of malaria parasites* by no means proved that their fever was malarial, for most members of those races have had malaria throughout their lives, and the parasites can commonly be found in their blood *when they feel perfectly well. Even among* British troops the presence of parasites did not prove that they had malaria alone. And the failure to find parasites, especially among British troops who had not previously had malaria, could not, by universal agreement, exclude the disease. On the other hand, a single brief high fever, preceded and followed by afebrile periods, could hardly be due to anything but malaria, and such fever *occurring every second or third day provides evidence* as near pathognomonic as any in the whole field of medicine. Here, indeed, is a good example of the extraordinary assumption, so commonly made now in the medical world, that the evidence of the laboratory is inevitably superior to the clinical evidence.

And the premise that there is something wrong or "unscientific" in giving treatment before the diagnosis is made is itself damnable. Diagnosis is not an end in *itself but the means to an end. To give quinine or* mepacrine to those who in fact are free of malaria cannot do them any possible harm, and to give the drugs as soon as the disease is suspect can only do good.

A further defence of the order was that if soldiers were wrongly started on anti-malaria treatment, they would unnecessarily be held in hospital, since the official scheme of treatment, until February, 1945, lasted 2 weeks. But this implied that it was in fact correct automatically to keep soldiers in hospital because they had had a malarial attack—a question to which I shall return.

A comparison between this order and a number of orders issued in connexion with certain other diseases is interesting. Thus, a memorandum of August, 1944, about scrub-typhus, said: "If a suspected or definite typhus case has come from a malarious area he must forthwith be given a full course of anti-malarial treatment *whether or not malarial parasites are found in his blood-stream.* Neglect of this precaution has resulted in deaths . . ." (my italics). In other memoranda it was laid down that all soldiers who had been wounded, who were admitted to hospital for ordinary surgical operations, or who had severe anæmia should be given *anti-malaria* treatment. Thus if a medical officer had the best clinical evidence for supposing that a man had malaria he was strongly discouraged from prescribing anti-malaria remedies; but if he knew that a man had one of these other conditions he was *compelled* to prescribe these remedies!

It was not surprising that this order was widely ignored. In many units officers and N.C.O.s were not evacuated when their regimental M.O. thought they had malaria, but were given quinine and mepacrine on the spot, even though the rank and file were disposed of through the correct channels.

A company commander of a field ambulance who had been in the 36th Division during the advance from Myitkina told me that of course his own personnel who developed malaria did not become casualties as they should have done. They were immediately given the drugs and as soon as their fever had subsided returned to duty. "If we had done otherwise," he said, "the unit would have become incapable of functioning and the evacuation arrangements would have broken down completely."

The commanding officer of an infantry battalion told me that when his unit was on the Arakan Front it acquired great prestige because of the almost complete absence of malaria among its personnel. In fact there were many cases of malaria, but they were kept in a special tent, having the drugs until their fever subsided; they then returned to duty. This policy was continued even when parts of the battalion were in contact with the enemy. On the occasion of visits by an A.D.M.S. or D.D.M.S., the malaria tent was struck and the casualties were hidden in the jungle, all evidence of *being thus obliterated.*

In such ways as these did individuals and in units diminish, *if only slightly,* the disastrous this order.

TREATMENT

Until February, 1945, it was laid down that all of malaria should be given the following course of tr ment: Days 1 and 2, quinine gr. 10 t.d.s.; days 3 mepacrine 0·1 g. t.d.s.; days 8 and 9, no drugs; d 10 to 14 pamaquin 0·01 g. t.d.s. (After February, a course of mepacrine only, lasting 7 days, was institu Now it was officially decreed that pamaquin was a drug, and an order was issued that all those taki must be kept at rest. Since it was given at the end of course, fighting soldiers could hardly be sent strai back to duty even two weeks after beginning their t ment. It was customary in many medical units to re them for a further week or two. A Fourteenth A operational research group, investigating a sampl soldiers admitted to a casualty-clearing station in Kabaw valley during October, 1944, found tha average time spent there by Indian *other ranks on a* of malaria was 23·5 days.

Pamaquin was apparently prescribed for two reas first, *to destroy the gametocytes* and thereby dimi the number of infective mosquitoes; and second hinder relapses. But the vast reservoir of native pop tions took neither pamaquin nor anti-mosquito cautions, which disposes of the first reason. And the pamaquin may have *a slight effect* on hindering rela this could not possibly counterbalance its adverse effec immobilising vast numbers of men in hospital. More the use of pamaquin was for about a year compul even for troops having suppressive mepacrine (whic an immeasurably more effective way of preven relapses). It commonly happened that soldiers actu relapsed while having pamaquin. In this event t medical officers who obeyed orders began the 14-day course again, with the chance of their pa relapsing once more when *taking* pamaquin for second time.

After the "mepacrine only" course was institu the average stay in hospital of malaria cases doubl decreased very considerably. Nevertheless, it was to retain men for the *full 7 days* at least, and in m units for considerably longer. Admittedly, no order issued insisting on this, but no order was issued encou ing the practice of discharging men while still treatment.

CONSEQUENCES OF THE OFFICIAL POLICY

When a soldier belonging to a static unit in a b area entered hospital with malaria, he *could* be retu straight to his unit as soon as his course of treatment over. He was a casualty, therefore, for *only* 2 weeks. But the soldier who fell ill near the Front to be evacuated for a considerable distance; so problem arose of returning him to his unit when charged. The fact that as a rule the Front was consta fluid, changing its position perhaps by many miles in day, further aggravated the difficulties. During earlier phases of the campaign the flood of malaria c was so great, in relation to *the number* of forward h that the orders making it inevitable for all men with disease to remain in hospital for over 2 weeks ca repeated evacuations from hospital to hospital, farther away from the fighting zone. In 1943 many who developed malaria in *the* Arakan did not fin come to rest until they had reached such places Bangalore and Rawalpindi, thousands of miles a There was naturally a very long interval *before* such arrived back at the Front again. Statistics as to average time malaria cases remained *hors-de-combat* rapidly became free of all symptoms after the mœbic remedies were begun had been discharged say, two weeks, it would have mattered very little heir symptoms in fact been due to another cause the entamœba. To those who did not recover the could have done *no* harm.

other source of error caused by the excessive con- ation on the microscopic aspects of amœbiasis is the *E. histolytica* discovered in a man's stools may ecessarily be responsible for his symptoms—just alarial parasites may not be responsible for fever. aps vegetative forms of the organism are always d by active disease, but it has been widely thought any years that in countries where amœbiasis is mic a high proportion of the natives habitually the cystic forms, though free of all symptoms. that even in temperate countries such as England passers are by no means rare. Commonly, therefore. ers with alimentary symptoms due to another cause amœbiasis, or even those with vague complaints sychological origin. were given the recommended e of anti-amœbic remedies because of the coinci- al presence of *E. histolytica* cysts in their stools. situation is further complicated by the fact that may be considerable difficulty, even for the expert, ifferentiating *E. histolytica* cysts from other cysts only found in the bowel, as was recently emphasised ershaw (1946) and Hill (1947). It can hardly be ned that many soldiers in forward medical units in na, the laboratories of which were often staffed by y trained technicians, were wrongly considered to arbouring *E. histolytica* cysts.

TREATMENT

rhaps the most striking feature of the Army policy rds amœbiasis was the length of time it caused men emain *hors-de-combat*. For the ordinary case an SEA medical directive dated December, 1945, pre- ed emetine, emetine-bismuth-iodide (E.B.I.), and iofon-enema courses lasting about 17 days. This followed by 'Diodoquin,' if available, for 20 days, therwise acetarsol or similar compound for 12 days. r an interval of 2 weeks from the end of treatment. ls had to be examined microscopically for 6 consecu- days. Clearly, a man could not be returned to his in the forward areas for the 2 weeks' interval, gh he might sometimes spend this time in a con- scent depot. The total time, therefore, between nning treatment and being ready to return to duty ; if diodoquin was used, a minimum of 8 weeks and ay. This naturally meant that cases of amœbiasis ld not be treated in the forward areas, but had to be uated a long distance, probably to such places as illa in Bengal or Madras. Moreover, the treatment rarely started immediately after the soldier reported in the forward areas ; commonly there was a delay ays or weeks (which in many cases could be ascribed the official policy of discouraging the making of ical diagnoses). And the delay between a soldier's harge from hospital in, say, Comilla and his return to forward unit was often measured in numbers of weeks. eral of which were commonly spent in a convalescent pot. Hence soldiers with the mildest attacks of œbiasis were often casualties for many months.

A full course of treatment with E.B.I. and chiniofon tention enemata, followed by diodoquin and one of e arsenicals, was also prescribed for soldiers who had symptoms of amœbiasis but were found to be passing ts.

In the treatment of amœbiasis it is widely believed at a variety of drugs are complementary, and this was e reason why, in the Burma theatre and India during e war, it was at first customary and later obligatory give at least three groups of drugs, provided they were all available (which was *often not* the case): first, emetine injections followed by E.B.I. by *mouth* ; *second*, chiniofon retention enemata, or alternatively *diodoquin* ; and third, certain arsenical drugs, such as *acetarsol*, carbasone, and amibiarson. In addition, sulphaguanidine or other sulphonamide was commonly given, and in severe and relapsing cases penicillin. In treating amœbiasis greater stress is put on *régime* and *dietary* measures than in treating most other diseases. *Rest* is deemed necessary not only as an aid to recovery *but also* to minimise the toxic effects of emetine on the heart, and in the Burma theatre it was usual to order soldiers to remain in bed for their whole emetine course and often for longer.

Now, the severity of an attack of amœbiasis varies *infinitely*, and the untreated natural course of the disease is of exacerbations and remissions, which can be of varying lengths. The difficulties of assessing the value of a remedy for such a disease are very considerable even when it is given alone, and when numerous remedies are given simultaneously are even greater. So far as I know, nobody has yet published the necessary large-scale controlled series in which alternate cases are given a standard combination of remedies and the others this combination plus the preparation to be tested. In the absence of such evidence, treatment is a matter of opinion, and I offer the following propositions :

1. The reasons for supposing that *rest* and *dietary measures* can influence the course of amœbiasis appear to be no stronger than the reasons in favour of these remedies in other circumstances. That if a man lies down all day his diseased colon will heal, but that if he walks about it will not heal is unlikely ; and it is hardly conceivable that finely divided cellulose in the colon can prevent its healing (the residue-free character of a diet being considered the most important quality). The advocacy of rest to minimise the toxic effects of emetine on the heart appears, *a priori*, equally *groundless*. *Probably*, therefore, the right policy is the general policy I have suggested elsewhere (Todd 1949)—namely, that the patient's symptoms should determine his activities and the nature of his food.
2. There is no apparent reason for supposing that the use of *purgatives* in amœbiasis is in any way beneficial, while it must aggravate the diarrhœa.
3. There seems to be no good reason to think that the *arsenic-containing drugs* improve the results of emetine and the oxyquinolines alone. However, provided their exhibition is not allowed to interfere with the patient's return to work or duty—a most important proviso—they can hardly do harm.
4. Since most attacks of amœbiasis clear up with emetine and the oxyquinoline compounds, *sulphonamides* and *penicillin* are best reserved for cases whose attacks do not take so favourable a course.
5. There is no convincing empirical evidence in favour of the use of E.B.I. by mouth rather than *emetine* by injection. The findings of Rail (1947), in one of the few papers in which any attempt is made to compare the effects of the two preparations on a series of otherwise similar cases, suggest that in fact E.B.I. is not superior, but is possibly inferior, to emetine.
6. If emetine injections do not relieve acute symptoms within a few days, they are unlikely to do so later ; so there is no point in continuing the drug. If emetine is successful, probably nothing will be gained by continuing to give it, or E.B.I., for longer than about 10 days.
7. Oxyquinoline compounds are commonly given by both rectal and oral routes ; it seems reasonable to suppose that the lesions near the anus are best dealt with by enemata, and lesions higher up by the substances coming down from above. Since these drugs rarely cause toxic effects, it is doubtless sound policy to continue them by mouth for some time after the symptoms have subsided ; but long-continued administration per rectum can be condemned because it is trying to the patient and almost demands hospitalisation.
8. In a community where some 15–20% of people are passing *amœbic cysts*, *there is little* point in treating

victim of this disease becomes more ill with each attack until finally he fails to respond at all to treatment as long as he remains in the tropics.

DIAGNOSIS

Though no regulation was issued by the Army authorities urging that anti-amœbic treatment should not be given until the organism was isolated, it was nevertheless said or implied in the Army publications that the diagnosis should not be made until the *Entamœba histolytica* was discovered. Thus, the *Memoranda on Medical Diseases in Tropical and Sub-tropical Areas* (1942) states that "the diagnosis depends on the detection of *E. histolytica* in the motions." The instructions issued by ALFSEA in 1944 said: "For successful diagnosis of amœbic dysentery a 'red hot' stool is necessary. . . . If medical officers and pathologists are both 'on their toes' early diagnosis is assured. In cases strongly suspect but with negative stools sigmoidoscopy or proctoscopy and microscopic examination of ulcer scrapings may provide the answer . . ." These statements strongly suggest that the microscope is the only proper means of diagnosing alimentary amœbiasis. A similar conclusion is reached in such standard works as Manson-Bahr's *Manson's Tropical Diseases* (1940). And in the many papers on amœbiasis which have appeared during and since the war, though the great difficulty of diagnosing the disease is stressed, it seems to be generally assumed *that the clinical evidence provides insufficient grounds* for starting treatment.

Yet it has long been agreed that *E. histolytica* can be very hard to find (cf. Hayward 1946). And it is also widely realised that many cases of amœbiasis—the very cases from which it is most difficult to isolate the organism—do not reveal the "classical" picture with marked symptoms and "anchovy sauce" stools, but merely mild intermittent diarrhœa (without blood), vague abdominal discomfort, anorexia, nausea, and perhaps loss of weight.

In Burma the emphasis on the microscopic, as opposed to the clinical, findings inevitably delayed the initiation of treatment. A soldier might report sick in the forward areas and be evacuated through many medical units until, after perhaps a lapse of weeks, some pathologist would succeed in isolating the entamœba or some clinician would finally decide that the clinical evidence was sufficient to warrant beginning the exhibition of the drugs. Alternatively he would improve sufficiently with the aid of a chalk mixture to be discharged after a week or two with some such diagnosis as "gastro-enteritis" or "dyspepsia," to be later readmitted with a relapse. Sometimes soldiers with persistent symptoms typical of low-grade amœbiasis would be enthusiastically investigated by barium meal and enema radiography, gastric analysis, sigmoidoscopy, and stool examination. All these *studies being negative*, the conclusion would be reached that, organic disease having been "excluded," they must be neurotic.

When stationed with an Indian general hospital at Agartala in Bengal during the summer of 1945, with the help of Captain M. S. Khera, I.A.M.C., I made a special study of twenty-four Indian soldiers admitted under my care during a period of about 10 days. In coming from the Burma Front they had all passed through several medical units before reaching us, the average time they had been casualties then being 38 days. In these units each had had on the average about four stool examinations. Vegetative *E. histolytica* were of course never found. The main treatment they had received had been the ordinary chalk or kaolin mixtures; none had been given anti-amœbic remedies. The reason for withholding these remedies was not that an amœbic infection had been unsuspected, for on many of the documents appeared the provisional diagnosis "? amœbiasis"*; and this commonly appeared on the front of the field medical card over the signature of the M.O.—a signature then about 38 days old.

Their *histories* were strikingly similar. All said been unwell for 2-5 months (though this figure taken as accurate). All complained of anorexia and a discomfort, pain, or distension, particularly after Ten (42%) stated that they had had much vomitin had had a certain amount of diarrhœa, often in spell *nating with constipation, though this was not th* complaint. Thirteen (54%) stated that they had so passed blood in the stools. All complained of weakn *some loss of weight. Thirteen (54%)* had soreness tongue.

On examination, none had severe abdominal ten Nine (38%) were moderately tender over the ascen descending colons or both. Two (8%) had palpable livers. Sigmoidoscopy was performed on twenty case mucous membranes of four (20%) appeared nor eleven (55%) congested in places, swollen and " and covered to various degrees with thin tenacious and of three (15%) merely flecked with a little mucus. only could an ulcer suggesting amœbiasis be seen.

Smears taken at sigmoidoscopy were examined scopically, but vegetative entamœbæ were never Each patient had one stool examined, also with n results, though the special techniques employed to i the chances of finding the organism were not used.

These men were immediately treated as if the amœbiasis. All were given *ten injections of* e gr. 1 on successive days, coincidentally with ten ch enemata, followed by 'Amibiarson' for 10 day addition, all were given vitamin concentrates, b many had symptoms suggesting vitamin-B, defici Twenty (82%) rapidly became free of abdominal toms; even when asked leading questions none admit that his relief from dyspepsia and diarrhœ anything but complete. Three (*13%*) *said they* l diarrhœa and their indigestion became much l though still troubling them slightly. The remaini still complained of a good deal of indigestion, bu he had improved.

From all this I conclude that *the diagnosis of amo should not wait upon the discovery of the organis* should be made on clinical grounds. Even if it wer that *E. histolytica* could always be isolated *from* with amœbiasis within a short time, the pract *refusing to diagnose* that disease on clinical gr could, during the Burma campaign, be condemne practical reasons.

It was agreed that for rapid microscopic diagnosis it be necessary to examine repeated fresh stools from patient after he had taken salts and to perform sigmoido and take swabs from the bowel. The entire pathologica of a forward medical unit might consist of one jema sergeant technician working in a small tent. When cas were pouring into the unit he could not *possibly* spare the from such other duties as studying innumerable blood t testing urines, and performing blood-counts to spend poring over vast numbers of fresh *stools*. The main why the cases just described had only had about four examined, though they had been in hospital over five was doubtless the pressure on the *pathological* services units through which they had passed.

The *only rational objection* to the practice of tre amœbiasis on clinical grounds—for the *objection* th do so is "unscientific" may be dismissed *out of* h as in the case of malaria—*was* that it would cause who were in fact free of amœbiasis to be *given* amœbic remedies. And the prescribed course of t ment and aftercare made it *inevitable* that soldiers amœbiasis should be *casualties* for at least *two mo* *But I hope to show* later that this long minimum p was unjustified. If soldiers with "*clinical* amœbia

---

* It may possibly be objected here that the cases were examples of primary vitamin deficiency, cured not by the amœbic remedies but by the vitamins. But there seem doubt that the dyspeptic symptoms had long prece mouth symptoms, while at that time the rations of the fo troops were very *good*.

A piece of fresh normal aorta, still warm, is not easy to get from our pathologists, and surgeons are easily insulted. We must send one of our girls down to the slaughterhouse; for the students must have their 90 microgrammes ($1{\cdot}98\times10^{-7}$ pounds) of flesh. Our histology department is "out of aorta," but a sheep's will do.

Our messenger returns. "They say you have to write to Dr. X of the Ministry of Health. It requires a permit." I ring WHI. 4300, and arrive, via several female voices, at that of the arch-aortamonger himself (thought: if he specialises in the second portion of the aorta, he will be entitled to a second arch). I explain my predicament. Ominous apologies, including the words "red tape" follow. He ends at last by saying that unfortunately he is no longer dealing with these matters (I suppose these cabinet-type reshuffles must go on at all levels all the time, and that this is the result of a thoracic purge). He refers me to their Kensington branch where a Mr. Y (this lack of a medical qualification disturbed me) will fix me up. Again the series of female voices. "Mr. Y is not available, but Mr. Z knows all about that sort of thing—but, no, I can really tell you myself! You write to us, we authorise it, and the Ministry of Food will grant a permit. No, in a *straightforward* case like yours it shouldn't take more than a few days."

It will probably mean cutting the aorta ration to 45 microgrammes ($9{\cdot}9\times10^{-8}$ pounds), but all must make sacrifices these days. Ours will be a rabbit.

* * *

I really must give my hobby horse another gallop. When it last had an outing I suggested that Sir Ernest Gowers should try to persuade medical writers, as well as civil servants, to give up verbose jargon and to use Plain Words instead. But now that I have joined up as a G.P. I can see why his first attack was against civil-service English.

I learned that I had permission to practise in a remarkable letter which reads as follows:

> "Your application . . . has been considered by the Committee and they have decided to grant the application, subject to the exclusion of the provision of general medical services by you, in those parts of the Executive Council's area where the Committee declared the number of doctors to be adequate, published in the *Lancet* of 30th July 1949, and *British Medical Journal* of the 6th August 1949, and any subsequent amendments published prior to the date of this letter. Such restriction is subject to the right of appeal against the decision of the Committee to the Minister. . . ."

The essential phrase here is, I think, "decided to grant the application," which evidently means that I may practise.

I soon received a bundle of forms and documents. To my delight I found one headed STATUTORY INSTRUMENTS, which contains the original of a now famous sentence: "Every woman by whom or on whose behalf a claim for maternity benefit is made shall furnish evidence that she has been, or that it is to be expected that she will be, confined by means of a certificate given in accordance with the rules for certification . . . or by means of such other certificate as the determining authority may accept. . . ." Such is the art of obstetrics in the Welfare State.

* * *

A simple case of hiccup (or hiccough) was shown at the physicians' meeting—a refreshing change from the rare and bizarre cases usually appearing at these learned gatherings. However, it was soon clear that this problem was frightfully complicated, for the hiccup may persist after the crushing of both phrenics, and in their enthusiasm to explain the movement some of the physicians began to imitate hiccup, with emphasis on the hic rather than the cup. At one point one wondered whether the whole audience might become afflicted, as in the medieval orgies when communities would succumb to some hysterical outburst (see Dancing Mania). Fortunately, the tone of the meeting was restored by the pronouncement of the neurologist, that we were dealing with a typical example of Focal Epilepsy of the Hind Brain.

ascertained cyst-carriers—unless perhaps they are engaged in preparing food. Patients with the symptoms of amœbiasis should be treated, even if the organism is not found. Those with the organism but not the symptoms should not be treated.

If these propositions are accepted, the ordinary attack of amœbiasis should be treated along the following lines. Injections of emetine gr. 1 are given daily for, say, 10 days, simultaneously with diodoquin by mouth, and perhaps with chiniofon enemata. During this period the patient, unless he is very ill, is encouraged to be up and about, except for several hours after the enemata (which, if given in the evenings, should not interfere with his activities). He has a full diet, so far as practicable to suit his tastes, and no purgatives or other ancillary drugs. For a further period afterwards he possibly has more diodoquin. Patients who are not completely symptom-free after this course, or who quickly relapse, should, after an interval, be given a further course of the same drugs accompanied or preceded by sulphonamides and penicillin and perhaps followed by other remedies.

While the problem of the treatment of amœbiasis remains obscure, it seems to me reasonable to adopt this scheme rather than others more complicated. The onus of proof should rest on those who state that long spells in bed, fluid or residue-free diets, regular purgative drugs, and a long course of E.B.I. are valuable.

If these conclusions are sound, the minimum period for being a casualty from amœbiasis should have been measured in small numbers of weeks (as it was measured by those who treated cases in forward medical units and ignored the regulations). The combined emetine, chiniofon, and diodoquin course could have been started in a casualty-clearing station or other equivalent forward unit immediately after admission. After some 10 days the patients who were still unwell, and those whose attack was a recent relapse, should have been evacuated to base hospitals for further treatment and, if necessary, invaliding. The remainder—as a rule the great majority—could then have been given an intensive toughening course (if coming from front-line units) and after a few days could have been discharged to duty, possibly with a supply of diodoquin or arsenic compound to take for a few weeks. Admittedly, until fairly late in the campaign, diodoquin was unavailable, and for the first year or so chiniofon was scarce; but in so far as there was a shortage of these compounds, the forward units could have been given priority.

It may be objected that a proportion of soldiers treated in this way would relapse shortly after returning to their units and become casualties again. But it would have been far better that a few men should become casualties twice than that a large number should be hors-de-combat for many months at a time. Those who had two attacks within a short period should have been sent to the base areas, to prevent their becoming casualties a third time.

DISCUSSION

My conclusions about amœbiasis thus resemble my conclusions about malaria. For the official policy towards the diagnosis and treatment of the two diseases was wrong for similar reasons: in diagnosis the microscopic aspects were given far too great an emphasis by comparison with the clinical, and in treatment soldiers were caused to remain hors-de-combat far longer than was necessary. In the case of malaria this policy was responsible for soldiers remaining undiagnosed for days and being casualties for weeks; in the case of amœbiasis it meant that soldiers often remain undiagnosed for weeks and became casualties for many months.

During three years in the tropics I discussed these problems with numerous clinicians, and many admitted that they too believed that amœbiasis should oft diagnosed on clinical grounds. Pathologists, on the hand, tended to have the opposite opinion, which is altogether surprising. Some of the advocates of clinical approach nevertheless seemed a little f they would *give* the anti-amœbic remedies without covering the *E. histolytica*, but they hardly liked t publish the fact openly, doubtless having a fear of bei dubbed "unscientific" by some scorning patholog With rare exceptions those who committed themsel to print seemed to take for granted the diagnost superiority of the microscope.

No European civilian in the tropics would stay i hospital for two months with a mild attack of amœbia And the difference between the lives of civilians and soldiers can no more excuse this prolonged hospitalisati for all soldiers with amœbiasis than it can excuse t practice of keeping every soldier with malaria in hospit for two weeks. The arguments against a minimu period of hospitalisation for malaria apply equally amœbiasis. For any attempt to make fixed regulati for a disease so variable, affecting soldiers wh conditions of life differ so widely, is surely unjustified

THE CANADIAN ROYAL COLLEGE

FROM A CANADIAN CORRESPONDENT

THE annual meeting and convocation of the Roy College of Physicians and Surgeons of Canada was he in Toronto on Nov. 25 and 26. This is the first ti that the college has been convened outside of Ottaw Parliament was in session and the halls of the Châte Laurier Hotel were not available.

The first day was devoted to scientific papers. T of these were given by the first winners of the med offered by the college for essays on original work b young investigators. The contest is open to the professi throughout Canada, provided that the essayist be n more than forty years of age. Dr. Euchariste Samso of Quebec, won the medal in the division of surger with his paper entitled Traitement Radical du Canc de la Tête du Pancreas; and Dr. W. Stanley Hartrof of Toronto, was awarded the medal in the division of Toronto, was awarded the medal in the division medicine with a study entitled Aspects of Experiment Choline Deficiency.

At the convocation the address in medicine wa delivered by Prof. C. E. van Rooyen (Toronto), wh spoke on Current Problems in the Diagnosis and Treatmen of Virus Diseases. The address in surgery was given b Dr. Frank Lamont Meleney, associate professor surgery, Columbia University, New York, who discu the Clinical Application of the Present Knowledge Antibiotic Therapy to Surgical Infections.

Fellowships were awarded by the president, Dr. W. Gillespie, professor of surgery in the University Alberta, to Prof. William Boyd and Prof. W. W. Barr clough (Toronto), Professor van Rooyen, and Profess Meleney, among others. Honorary fellowship wa bestowed upon Lord Webb-Johnson, immediate pa president of the Royal College of Surgeons of Englan who addressed convocation. In his citation Prof. W. E Gallie (Toronto) said:

> "During the eight years that he was president he brough about a change in the college that the previous hundre years had failed to do. When he took office it wa primarily an examining board, dignified, aloof, cold. No it has become the very centre of postgraduate educatio friendly, stimulating, warm-hearted. He has changed i from a museum to a laboratory, from an examination ha to a postgraduate school, from a place of many unhapp recollections to a place where happiness abounds. Al students of our art are welcome there and those from overseas will find in it not only a spiritual but also literal home."

stigation of the second question has proved that the dentist nor his personnel are exposed to any isk of mercurialism, provided that they handle y with the necessary precautions—wearing rubber talls while mixing it, and squeezing out the ous mercury with the aid of chamois leather. ger[4] found that in dental surgeries the content of y vapour was 0·0277–0·948 mg. per c.m. air, while urine of two people who handled the amalgam he mercury content was 0·023–0·078 mg. and 240 mg. per 4 litres: in other cases no mercury und. On the other hand, Parfitt and Herbert[2] eports on the Berlin school dental service where kers were found to be excreting mercury. Lately, an and Dannenberg[5] have concluded that "the t of mercury vapor with which the average dentist nto contact in his office or laboratory is not toxic. trations of the vapor were so uniformly low e study was terminated after fifty dental offices xamined instead of the one hundred originally l." The authors state that toxicity will result if y vapour exceeds 0·1 mg. per c.m. of air.

REATMENT OF PERNICIOUS ANÆMIA

–In your leading article of Dec. 3 you rightly ut the difficulty confronting the practitioner in ection of a preparation for the treatment of ous anæmia. However, one important point tted—namely, that of late years it has been ngly difficult to find, amongst all the parenteral tracts on the market, one that is really reliable. omitted this important point you sum up by that "the treatment of pernicious anæmia, still rests on the proper use of liver and desiccated- h preparations."

is hospital, during the past twenty years, patients g from pernicious anæmia have been treated in al clinic. We have therefore had an opportunity rving the same patients over many years and of the maintenance value of many extracts. From perience two important points emerge: (1) treat- must be controlled by periodic blood-counts, r reliable the liver extract used may have proved past: and (2) of recent years there has been a decline in the potency of liver extracts. There le evidence that other workers have had similar nce: and in the Oliver-Sharpey lectures, to you refer, Wilkinson[6] confirms the latter point ggests that the explanation lies in the use of so- "pharmaceutical" livers by the manufacturers.

arked has been this decline in potency of liver s in recent years that we welcomed the opportunity o us by Messrs. Glaxo Laboratories Ltd. to test s of vitamin B_{12} derived from botanical sources. the past six months we have treated with this ation fourteen patients who were suffering from rst attack of anæmia. All of them have given ous reticulocyte response followed by a rapid of hæmoglobin and red cells to normal levels. ition to these fourteen patients, we have success- reated relapses in eighteen patients who were ng for maintenance treatment by liver extract, ho had relapsed in spite of such treatment. Finally patients under liver maintenance treatment but relapse, who have been changed to treatment amin B_{12}, have volunteered that they felt better; such patients the red-cell levels have generally from 4·0–4·5 million per c.mm. to 5·0 million mm.

Whatever else may emerge from our experience, if the treatment of pernicious anæmia is to rest on the proper use of liver extracts as at present available, such treatment will be unsatisfactory. In our limited experience with vitamin B_{12}, we have yet to meet the patient that is not better for the change from liver extract to this preparation. We have little or no experience of the use of desiccated-stomach preparations and so cannot comment on this treatment.

Surely the position is that all pernicious-anæmia patients under treatment must receive adequate hæmatological control. If this condition is satisfied, then whatever treatment may be used it can be modified if hæmoglobin and red-cell levels are not maintained.

ANONYMITY IN BROADCASTING

SIR,—Your correspondence on anonymity on the B.B.C. puzzles me. How can one be anonymous on a television programme, unless one wears a mask and disguises one's voice? Surely the situation is becoming ridiculous, because if in fact such measures are taken to their logical conclusion no doctor could ever appear on any public platform unless speaking from behind a screen and billed as an unknown doctor. The point about this question of advertising is whether these public appearances are for the purpose of gaining patients; and I cannot see that any harm is done by doctors broadcasting by sound or television, or by their public appearance, so long as it is obviously not for the purpose of advertising themselves.

I feel that the entirely negative attitude of the General Medical Council is to be deplored, and that they should formulate rules for guidance on this important matter.

Urmston, Lancs. BERNARD SANDLER.

OPERATIONS FOR MITRAL STENOSIS

SIR,—It might perhaps have been desirable to mention, in your leading article of Oct. 29, the influence of pathological changes in the intrapulmonary arteries and arterioles upon the outcome of operations for mitral stenosis. An investigation by Larrabee et al.[1] emphasises the importance of this aspect.

They have studied post mortem 20 cases of well-established mitral stenosis, the patients having mostly died as a direct result of the mitral lesion. The lesions found in the intrapulmonary arteries and arterioles were medial hypertrophy, intimal fibrosis, and medial scarring; in 6 there was medial hypertrophy only. Owing to these lesions, the calibre of affected vessels was reduced, with consequent increased resistance to blood-flow at this level.

The question naturally arises whether direct relief of the mitral stenotic lesion by operation on the valve itself might fail to produce the desired effect in the presence of widespread intrapulmonary arterial resistance. Right-heart failure might still ensue under such circumstances even though the mitral obstruction had been relieved. Larrabee and his co-workers suggest that in mitral stenosis medial hypertrophy probably represents the earliest organic change in these vessels; that a vessel so affected remains flexible and capable of dilatation after alleviation of the mitral obstructive lesion; and that no relief of the intrapulmonary resistance may be expected in the presence of intimal fibrosis and medial scarring. A similar line of reasoning is applicable to the operation of Bland and Sweet,[2] in which a venous shunt is established between the dorsal-segment branch of the right inferior pulmonary vein and the azygos vein. It is natural to assume that optimal benefit would be expected

Letters to the Editor

ACADEMIC SALARIES AT CAMBRIDGE

SIR,—We ask you to publish the following facts relating to scales of stipends at Cambridge[1]:

	Non-medical	*Preclinical*	*Clinical*
Professor ..	£1950*	£2050†	£2500
Readers ..	£1800 and £1600	£1800 and £1600	£2000 and £1800
Lecturer ..	£750–£50–£1250	£750–£50–£1250	£850–£100–£1450
Demonstrator or assistant lecturer	£600–£25–£700	£600–£25–£700	£700–£25–£800
Departmental demonstrator		£350 (no superannuation)	

* Plus administrative payments up to £400.
† Plus administrative payments up to £300.

In certain cases (both medical and non-medical) there are additional pensionable payments up to £120. The scale for teaching officers ordinarily resident in college is £100 less than that shown.

For the medically qualified man these scales mean that if he teaches at Cambridge rather than in other medical schools, he may be at a financial disadvantage amounting to some £6000 of pensionable stipend during his first ten years of appointment (due to the low annual increments), and at a final disadvantage of over £400 of annual pensionable stipend. These considerations may weigh heavily with the man who lacks private means but has a growing family, for which the "amenities of Cambridge" ought not to be measured thus.

These scales were approved by the university on Saturday Dec. 3. Many eminent men, both medical and non-medical, opposed this approval, which in their opinion would create a grave risk to the future of medical teaching in Cambridge—a risk which was avoidable and which therefore should not be incurred. They pointed out that in a comparable university different decisions had clearly been made in the national interest, with a proper appreciation of the problems arising from the nationalisation of medicine and the Spens report. They were refused permission to disapprove only of those stipends with which they were obviously concerned, and were heavily defeated by a large non-medical vote.

*** On Nov. 19 (p. 970) we briefly summarised the arguments advanced in the senate on Nov. 1.—ED.L.

THE ANTERIOR TIBIAL SYNDROME

SIR,—In their excellent article of Nov. 19, Dr. Barham Carter and his colleagues put forward the hypothesis that a rise in tension is the essential feature in producing the ischæmia of this syndrome. Two findings are emphasised as significant evidence in support of this view:

1. The presence of old and recent hæmorrhages in 3 out of 9 cases. Since the biopsies were performed at three, four, and six months after onset, recent hæmorrhages are likely to be of little ætiological significance and old ones perhaps difficult to assess.

2. The associated lesion of the anterior tibial nerve, which was noticed in all their cases and which cleared up completely in 3. The authors suggest that this indicates a compression neuropathy, but is not this rather begging the question? While rightly giving prominence to this associated nerve involvement, the authors themselves suggest that "in those cases in which the nerve lesion recovered, the lesion may have been a mild and reversible type of nerve ischæmia."

In their extensive investigation, the electromyographic findings are particularly interesting. Of the 3 cases in which the extensor digitorum longus was examined, the response was normal in 2 and silent in the 3rd, whilst the corresponding tibialis anterior extensor hallucis longus were silent in all 3 cases. peculiar differential involvement of muscles is a experience of other observers, and cannot be disregarded in any hypothesis. That the tibialis an is subjected to greater strain than the toe ext fails to explain the differential involvement of th extensors themselves. Furthermore, tension wit single closed compartment must obey the la dynamics and tend to be distributed uniformly that space. The fact that arteriography showed n abnormal in all 4 cases where it was carried out significant addition to our knowledge, and vir excludes any permanent organic occlusion of the anterior tibial artery; while the negative oscillo findings some months after onset are perhap helpful.

It seems that this intriguing syndrome still with many of its secrets.

Liverpool. J. ROWLAND HUGH

MERCURY AS AN OCCUPATIONAL HAZAR

SIR,—In your issue of Sept. 10, I read the inter article by Dr. Agate and Miss Buckell on mercury p ing from fingerprint photography. The authors m the dangers of mercurialism amongst refiners, m makers, hatters, manufacturers of thermometers others. As a dental surgeon, may I make a few addi remarks regarding the hazard in my profession?

Our main filling material is amalgam—a silve mercury alloy—which is triturated in a mortar u sort of soft plastic dough is formed and is then fu triturated or "mixed" in the palm of the han either the dentist or his assistant. Excessive merc squeezed out until the material is plastic enough inserted into the cavity. This excessive mercury s be caught and kept under water with the rest o "waste" amalgam, but occasionally minute me balls escape and roll on to the floor.

From this procedure two problems emerge: (1 the patient be affected by the mercury alloy i mouth; and (2) are the dentist and/or his assi exposed to the risk of mercurialism?

The first question has been dealt with by St who suggested that quite a number of nervous di ances in modern man are due to chronic mercuria resulting from dental-amalgam fillings; accordin Stock these are worn away and dissolve very slow the saliva. On the whole, his findings were not acce by the profession.[2] There is, however, one form amalgam filling—the copper amalgam—which cont free mercury and is softer than silver amalgam. F recognised as a potential source of danger, it is less. Under the National Health Service regulat copper amalgams "are not to be regarded as perma filling materials, though they may be used . . . for conservation of deciduous teeth."

From time to time there are reports of idiosyncr to amalgam fillings, or rather to the mercury containe them. Bass[3] described such a case in a 15-year-old who had previously shown allergic symptoms to cury. After having a tooth filled with amalgam developed œdema of the lips and erythematous erupt on lip and cheeks. Similar eruptions occurred in ano child, aged 4 years, after taking calomel; when child was 7 years old, she developed œdema of the after the application of yellow oxide of mercury to eyelids. At 12 and 13 years of age the same reac took place after she had several teeth filled with a gam; on removal of the fillings the symptoms ce at once.

THE GUILLAIN-BARRÉ SYNDROME

—I have read Dr. Petch's article of Sept. 3 with nterest. During the war I observed cases of and polyneuritis following typhoid and para- inoculation. Of 10 such cases, 3 had severe culoneuritis with a protein content in the cerebro- luid (C.S.F.) of up to 500 mg. per 100 ml. This to study the problem very carefully, and to from a fresh viewpoint the pathogenesis of ritis associated with the "dissociation albumino- ique" of the C.S.F. Essentially my conclusions[1]

e Guillain-Barré syndrome is a non-specific neuro- gical syndrome that has no single cause.

nically cases may be divided into four groups: (a) those ed with chronic focal infection (in my series mostly pyogenic infections of bones, joints, or soft parts from war wounds); (b) those arising after infectious such as chronic sepsis, dysentery, typhoid, and ria; (c) those associated with inflammatory disorders astro-intestinal tract and liver; and (d) those arising ction of foreign protein (vaccine or serum).

ar as these four groups are concerned, it was d that the disorder arises from an unorganised on-specific allergic (parallergic) process, which ts itself as allergic-hyperergic (serous) inflam- in the peripheral nervous system and is usually ly severe in the spinal roots; it is thus funda- ly a pathergic reaction in the sense used by The "dissociation albumino-cytologique" bears marks of an exudate, rich in protein and poor , diluted by the C.S.F., and leaking into the hnoid space from the inflamed spinal roots and anes.

may explain the pathogenesis, but it does not on the ætiology. It is still uncertain whether believe is very probable—there is a further group s which owe their origin to virus infection. These have been the subject of lively discussion by n workers and especially Pette.[2]

A. BANNWARTH.

—I have read with interest the article on the n-Barré syndrome or acute infective polyneuritis Petch rightly emphasises the identity of the two ons.

rding therapy. I should like to call attention to ective character of the illness. This necessitates ministration of hexamine intravenously, of vitamins plex and C), and in serious cases blood-transfusion. seen several cases where the condition was greatly d by blood-transfusion. This has proved useful cases where recovery is delayed: 2–5 transfusions, 150 ml. of blood, have caused rapid improvement.

pest. T. DE LEHOCZKY.

—Dr. Petch has oversimplified the description of rome that is still the subject of controversy.[3,4] "syndrome" may be a generalised disease-entity ribed by Dr. Petch, and should be distinguished h and labelled "Guillain-Barré disease." As tch observes, this condition so closely resembles infective polyneuritis that the two names should arded as synonyms. This terminology has been d by Russell Brain in the latest edition of his logy.

consideration must be given to the Guillain-Barré ome, or infectious neuronitis, as many American ogists prefer to call the condition. This syndrome neurological manifestation of various toxic and infective conditions in which diagnosis may be difficult; this is particularly so with some of the neurological manifestations of infective mononucleosis.[4] The syndrome has been observed after the administration of sulphanilamides and pyrotherapy.[5] It has also been seen after exposure to mustard gas[6] and various infectious diseases—infective mononucleosis, diphtheria, infective hepatitis,[7] Malta fever, enteric fever,[8] and mumps.[9] I now exclude all these conditions and anterior poliomyelitis before accepting a diagnosis of "Guillain-Barré disease" or acute infective polyneuritis.

My experience of this disease in Iraq is not in keeping with Dr. Petch's statement that "complete recovery is the rule, but rarely the patient may die." All our physicians have come to regard the disease as serious; of 15 cases admitted to various hospitals in Bagdad, 8 are known to have died from respiratory symptoms. Dr. Petch's statement holds good, however, for our interpretation of the "syndrome"; in this group we have not yet come across a fatality.

Royal Hospital, Bagdad, Iraq. J. A. SHABY.

TORSION OF THE APPENDICES EPIPLOICÆ

SIR,—In connexion with the article of Oct. 1 by Sir Cecil Wakeley and Mr. Childs, the following case may be of interest.

On the evening of Oct. 21, 1949, a married woman, aged 30, was admitted to this hospital with a history that on the morning of Oct. 19 she had started to have generalised colicky pain across the abdomen. Twenty-four hours later pain began also in the right iliac fossa, at first only on movement but soon constantly. Nausea was present, but she had not vomited. When the pain first began the patient had diarrhœa, but since then had passed a normal motion. There had also been slight dysuria, and the patient stated that she was subject to occasional nocturnal frequency. Parturition had occurred eleven weeks previously, and the menstrual periods had not yet restarted; she had had two children.

The patient's temperature was 98·2°F, pulse-rate 80 per min., respirations 20 per min.; blood-pressure 130/90 mm. Hg. The tongue was very slightly furred and moist. On abdominal examination there was slight guarding of the upper part of the right rectus abdominis and well-marked tenderness in the right iliac fossa: a soft mass, thought to be omentum and distended cæcum, was palpable. On rectal examination no abnormality was detected. Acute appendicitis was diagnosed.

At operation a McBurney's incision was made. A little free fluid was evident in the peritoneal cavity. On exploration with the finger an indurated, mobile piece of tissue was felt and delivered in the belief that it was the tip of the vermiform appendix. However, it was immediately evident that the cæcum was clothed with very numerous appendices epiploicæ, and the hard object—a black, triangular gangrenous mass—was an appendix epiploicus which had become twisted. In fact its attachment to the bowel was by then so precarious that if left alone it would soon have been loose in the peritoneal cavity. On removal of it ligation of its narrow pedicle was found to be unnecessary. The normal vermiform appendix was also removed. The peritoneum, muscle, and external oblique fascia were closed with catgut. The skin was closed with 'Nylon' and clips. The abdomen was not drained. The patient made an uninterrupted recovery.

The usual explanation of torsion of an appendix epiploica—which tends to occur in obese arteriosclerotic subjects—is that as the appendix enlarges by the deposition of fat the elastic vein is forced to twist around the more rigid artery. This leads to venous congestion at the neck of the appendix and a continuation of the "hæmodynamic torsion" described by Payr. In this case, however, the patient was a young adult, who certainly was neither arteriosclerotic nor obese. One is

to follow only when the intrapulmonary vessels are still capable of dilatation. The patients upon whom Bland and Sweet operated were subject to attacks of acute pulmonary œdema, often accompanied by hæmoptysis. They were relatively well between such attacks and showed only slight cardiac enlargement.

Bland and Sweet suggest that the procedure should be reserved for such patients with a fairly normal cardiac output. The operation offers a safety-valve for preventing attacks of acute pulmonary congestion, and were it later extended to a wider field in the treatment of mitral stenosis, structural changes in the smaller pulmonary arteries and arterioles should be carefully considered in assessing the ultimate result.

PERAXILLARY APPROACH TO THE STELLATE AND UPPER THORACIC SYMPATHETIC GANGLIA

Sir,—When Prof. R. H. Goetz, of Cape Town, visited this country last summer he persuaded me to adopt the peraxillary approach to the stellate and upper thoracic sympathetic ganglia. For the last few months I have used this approach, and as I have had many requests for a description of the technique, I should be grateful if you would allow me to give a short account of this.

Without going into the details of the anatomy of the sympathetic system, the operation consists in the removal of the second and third thoracic ganglia with the intervening chain, or alternatively, if it is desired to be strictly preganglionic, section of the chain below the third ganglion and of the white rami to this ganglion and to the second.

The patient is placed in the lateral position and wedged suitably on the table. The uppermost arm is extended to about 130°, drawn forwards, and placed on an arm-rest. It is important not to hyperextend the arm too far over the head, because on one occasion I had a temporary brachial-plexus palsy, due to the fact, I think, that I probably leant on the hyperextended arm during the course of the operation.

An incision is then made transversely across the axilla at the level of what is judged to be the second intercostal space. The obliquity of this incision depends upon the obliquity of the ribs in the particular patient; this can be felt through the axilla. The incision stretches from the latissimus dorsi posteriorly to the pectoralis major anteriorly. Either of these muscles may be partially incised, but I have found this necessary on only one occasion when a few fibres of the posterior border of the pectoralis major were incised to give better exposure.

The incision is deepened through fat and glandular tissue down to the intercostal space, bearing in mind that in the posterior part of the wound there lies the long thoracic nerve—the only structure of importance to be avoided. I usually do not see this nerve, but I am careful not to extend my intercostal incision too far backwards for fear of cutting it.

The second intercostal space having been exposed and identified, an incision is made through the intercostal muscles—a process which, because of the obliquity of the fibres in this region, is often more of a scratching than a clean incision. The anæsthetist is warned, and the pleura is entered. A retractor is then placed between the second and third ribs, and the best instrument for this purpose is half of a Tudor Edwards spreader, with the crossbar removed. I have found that a Tuffier retractor is not strong enough. The intercostal space is forcibly enlarged to about $1^1/_2$–2 in. The lung is allowed to collapse, and a moist gauze roll, 3 in. wide, is inserted into the pleural cavity, which, with the tail of the roll outside the wound, helps to keep the lung out of the way. A spatular retractor is inserted, together with a malleable light. It is then usually possible to see satisfactorily the upper part of the thoracic sympathetic chain shining through the parietal pleura. The adjacent intercostal veins, which in other approaches may cause such trouble, can be readily identified and avoided. I find it best to identify the stellate ganglion and the second and third thoracic ganglia before the parietal pleura over them is tampered with; otherwise the slight oozing which occurs as soon as the pleura is incised tends to mask the anatomy of these parts. In order to effect identification, a pair of lobectomy scissors is inserted into the cavity,
and the neck of the highest rib is identified by pal
the scissors. The ganglion lying on this rib is t
ganglion, and it is the two ganglia below this whi
removed.

At this stage the pleura is incised with a sp
handled knife, fitted with a no. 12 Bard Parker bl
has rather a scythed or hooked shape. The sp
handle is that to which I was introduced by Mr. Bro
of Birmingham, and which I use in hypertension
The pleura is incised over the required distanc
sympathetic chain seized immediately below the
glion. By dissection with the no. 12 Bard Parker
long-handled lobectomy scissors, together with
gauze held on long artery-forceps, this chain i
up and the required length removed. The mall
retractor, and gauze roll having been removed,
Edwards spreader is released and withdrawn, an
expanded by the anæsthetist.

No closure is necessary other than suturing th
continuous 'Nylon.' The patient may get up o
day, and so far I have had no trouble with pleur
or other intrapleural complications. Penicillin is
operatively for three days, and postoperative p
trolled in the usual manner. This postoperative
I believe, inversely with the amount of care with
ribs are retracted. If this is done slowly and gen
considerable degree of spread can be attained w
slight amount of trauma.

This communication is in no sense an a
claim priority, or indeed any credit wha
describing an operation which has been devel
where and will, no doubt, be fully described an
by its originator. I can only add that I have
the operation eight times and I feel that it is an
which deserves serious consideration. It is far
matic and far more anatomically certain
posterior approach. It is no more traumatic
anterior approach, and is agai
and a simpler procedure when
chain below the third thoraci
know that the claim is made that this gangli
exposed through the anterior approach, but
cannot invariably be substantiated.

Director
Department of

Guy's Hospital,
London, S.E.1.

AN EPIDEMIC OF ACUTE NEPHRIT

Sir,—I read with great interest Dr. Razza
in your issue of Oct. 15.

I treated 10 cases of acute nephritis in a mo
epidemic form during Dr. Razzaz's experience
the Palestinian refugees at the Jordan Red
Polyclinic in Amman. My cases were among
to-do. Thus bad living conditions and undue
to cold and damp weather had not much to do
epidemic. Moreover most of my cases were i
and almost all were accompanied by respiratory i
(especially acute tonsillitis), or preceded by
infection within the previous three weeks.

Diagnosis was based on the presence of œdema
blood-pressure; and laboratory examination
revealed albumin with casts and red blood-cell
numbers. All cases were treated with intra
injections of penicillin in a single large dose, in
to ordinary dietetic and diuretic measures. My
doses of penicillin are as follows: (1) under 1 yea
100,000 units in 1 ml. of distilled water; aged 2-
200,000 units in 2 ml. of distilled water; older c
500,000 units in 5 ml.; and adults, 1,000,000
5–10 ml. All 10 patients recovered in 7–10 day

Thus I agree with Dr. Razzaz that the dose
Fleming[1] were too small, and that larger dose
have given better results.

Djamil Faik Tutu
Under-Secretary of State for

Amman The Jordan.

L. WYNN HOUGHTON.

HYPERSPLENISM WITH ARTHRITIS

-Dr. Gauld commences his interesting article of 3 as follows: "Hypersplenism was first described seman and Doan (1939, 1942)." But the term splenism" was certainly in use by Naegeli, rhaps other hæmatologists on the Continent, 1929. Otherwise I could not have written the g in 1929[1]:

> n regard to the functional activity of the spleen it robably become more and more convenient to speak *persplenism* and *hyposplenism*—by analogy with the *hyperthyroidism* and *hypothyroidism*, *hyperpituitarism* *ypopituitarism*. It will probably also be found that are various forms of hypersplenism and hyposplenism sponding to involvement of the various functions e spleen (and reticulo-endothelial system), apart from ow well-recognised function of the spleen as a blood- roir (Barcroft, &c.)."

xplains the idea of there being various "selective plenisms"—a subject which has been so well out by Wiseman and Doan and other modern and supported by their clinical observations. observations are, as Dr. Gauld points out, still d to throw light on, and confirm, doubtful points.

n, W.1. F. PARKES WEBER.

THE FIRST MEDICAL EXAMINATION

—As chairman of the biology examiners for the B. examination of the University of London, I like to comment on the article by Dr. Johnson r issue of Sept. 17.

curious that Dr. Johnson should think that the e of the first M.B. examination is to select appro- students for a medical career. Surely mere selec- not the purpose of this or any other examination. amination is a test of a student's knowledge in a lar subject, and it is the examiners' sole duty to at the student has attained a sufficient standard. first M.B. examination, this standard is an adequate dge of chemistry, physics, and biology—the basic s on which his future medical studies depend. xamination gives the student the opportunity to is intelligence, but intelligence without knowledge t let a candidate through any examination; this applies equally to later examinations in a medical t's course. Therefore the selective action of an ation is only incidental.

s widely believed that the external first M.B. ation is competitive, but this belief is completely Theoretically it is possible for all candidates to for all to fail. Unfortunately too high a percentage reach the requisite standard. The fault for this many instances not in the intelligence of the ts but in the inadequacy of the training, especially ools. Dr. Johnson would have done well to note e figures of passes among internal students, who tudied at the various colleges and medical schools university. Here the usual pass percentage is in ghbourhood of 60% and is often higher, but these ts have had the benefit of pursuing a course of g under experienced teachers and in laboratories good facilities for practical work. In schools, on her hand, usually only one or two students are aiming at a medical career, and they have to be included in the same class with other students whose aims are different. The school teacher therefore has to devise a course which will more or less suit all his students, which is often unsatisfactory for all. Furthermore, the facilities for practical work are often inadequate and the time limited; for many school-children preparing for first M.B. (and Higher Certificate too) are not allowed to concentrate on the particular subjects for their examination, but also have to continue with other school subjects simultaneously.

It is not in the least surprising that selection by the University College board and "selection" by the first M.B. examination do not agree; the two tests have different objects and different standards, and apply different methods. One is intended to determine whether a student has reached a certain standard of knowledge in certain subjects; the other is an attempt to estimate, from a less definite basis and by more intangible standards, a student's intelligence and potentialities. It would be unexpected if there was agreement between the two results.

London, W.1. C. C. HENTSCHEL.

STATUS OF THE PSYCHIATRIC SOCIAL WORKER

SIR,—The libéral attitude which your journal has always maintained prompts me to write to you on this matter.

It is of considerable concern to many of us in the psychiatric service that the vacancies for psychiatric social workers are so many and the candidates so few. It is of even more concern that the salary-scales for these extremely arduous posts are quite inadequate. The Association of Psychiatric Social Workers has, to its great credit, refused to lower the standard demanded of all entrants, and to those of us who work with these valuable colleagues that is a matter for congratulation and due thankfulness. But, Sir, I submit that these officers are seriously underpaid; and that the periods of leave granted to them annually are inadequate for anyone who pursues such an arduous and exacting profession. I suspect that these matters have been the subject of inquiry, and it would be interesting to know the fate of the results of any such inquiry, and any recommendations made by the appropriate committee.

I feel sure, Sir, that any suggestion that the status of the psychiatric social worker shall be raised by increase in salary-scale would be supported by my fellow psychiatrists.

Taunton. R. SESSIONS HODGE.

TRANSIENT SPIROCHÆTÆMIA AND SPIRILLÆMIA AFTER DENTAL EXTRACTIONS

SIR,—In their very interesting article of Oct. 1, Dr. McEntegart and Dr. Porterfield contribute to the knowledge of transient invasion of the blood-stream by bacteria from the mouth as a result of dental extraction. Several workers have investigated the problem of bacteræmia following removal of teeth, but we have so far not been able to find any work on transient spirochætæmia, spirillæmia, or viræmia following such operations.

Clinical evidence speaks strongly in favour of such a possibility. We have observed several cases of acute spirochætal (non-syphilitic) or spirillar cystitis following the extraction of decayed or damaged teeth.[1] We have seen others where the bladder disease was found to be of this nature, dental foci were sought, and diseased teeth removed with precautions in order to search for spirochætes in the apical focus and around the roots;

Winchester.
DEREK G. JENKINS.

NASOPHARYNGEAL FIBROMA

SIR,—The following case adds one more to the list of cases of this condition.

In April, 1946, I examined a boy, aged $14^{1}/_{2}$, with obstruction of the right nostril. A reddish-looking mass was observed, and biopsy showed it be a highly vascular fibroma. At fortnightly intervals for two years the tumour was injected with different sclerosing fluids—phenol 2%, lithium salicylate, 'Ethamolin,' snake-venom, and sodium morrhuate. The growth neither grew nor retrogressed.

In July, 1948, he complained of pain over the right antrum, which proved to be infected. In addition slight exophthalmos appeared on the right side. Removal of the growth was decided upon, and this was performed through a modified lateral nasal rhinotomy. A good view was obtained of the growth, which appeared about the size of a tangerine and was attached to the sphenoid body with prolongations into the ethmoidal labyrinth. Great force was necessary to detach the growth from its base and there was considerable hæmorrhage during the whole operation, but this subsided on removing the main piece of growth. A blood-transfusion was begun during the second half of the operation, and in a few days the patient had recovered.

Recent examination shows slight persisting exophthalmos. There is no evidence of growth, but the right nasal cavity is spacious and crusting.

Liverpool Eye, Ear, and
Throat Infirmary.
JOHN MCFARLAND.

JEJUNAL PERFORATION WITH RESPIRATORY SYMPTOMS

SIR,—Ginzburg and Beller[1] have pointed out the difficulties in diagnosing perforation of the intestine by a foreign body, due to lack of any leading history, failure to demonstrate this type of foreign body with X rays, and the wide variety of clinical manifestations. According to Carp,[2] the usual pathological changes are early localised peritonitis, indurated inflammatory mass or tumour, abscesses, general peritonitis, and hæmorrhage. The following case does not fall exactly into any of these groups.

A male shop assistant, aged 24, was admitted to this hospital, with a tentative diagnosis of perforated gastric ulcer, on April 24, 1949. He said that a sudden severe pain had started ten hours before admission. The pain was felt in the epigastrium and in the left hypochondrium, was accompanied by nausea and vomiting, and became progressively worse, being especially severe during movement and breathing. The patient's bowels had last moved shortly before the onset of pain. The patient had passed urine that day.

On examination he lay quietly in a semi-prone position. His respirations were short and shallow, with brief periods of respiratory inhibition. He was slightly cyanosed, and there were no visible abdominal movements. The temperature was 99°F, pulse-rate 120, respirations 48 per min., blood-pressure 130/70 mm. Hg, and heart normal. Examination of the lungs revealed impairment of respiratory movement, especially on the left side. On auscultation faint vesicular breathing was heard. The tongue was dry but clean. The abdomen was normal in contour except in the epigastric zone, where it bulged. There were tenderness and rigidity, which spread and increased downwards and towards the left hypochondrium. Board-like rigidity was found in a small area two finger-breadths to the left of the umbilicus. Light palpation in this area elicited an excruciating pain. The patient cried out in agony and disliked being moved.

Operation.—Under spinal analgesia the abdomen was opened through a midline incision. Partial torsion of the jejunum, a small amount of fluid in the peritoneal cavity, and lymphadenitis were found. The torsion was reduced, and further exploration revealed a long foreign body protr from the wall of the jejunum below where the torsion been and moving freely with respiration. The thick e the foreign body was still in the lumen of the bowel occluded the opening in the bowel wall. The sharp po portion was projecting into the peritoneal cavity and directed upwards and outwards against the parietal toneum. The perforation was closed after withdraw the foreign body through the wall of the bowel, and meser glands were removed for biopsy. The foreign body w fish-bone, curved and thickened at one end, meas nearly 5 cm. The patient could not remember ha swallowed a fish-bone. Biopsy of the mesenteric gl showed chronic inflammation. The patient made uneventful recovery.

This case presents points of unusual interest from clinical point of view and from the findings at operat The question arose whether the symptoms were a ciated with a supra- or infra-diaphragmatic lesion. E respiration was accompanied by severe pain. Du the short period of respiratory inhibition the patient free from pain. The slightly cyanotic condition the shallow respiration suggested a supradiaphragm lesion; but fullness of the epigastrium, rigidity, ten ness, and the negative result of the physical examina of the chest led to laparotomy being performed in sea of a perforation of the stomach. The findings at opera showed that the shallow breathing and the agoni pain during respiration were due to the irritation of parietal peritoneum by the sharp point of the fish-b impinging on it with each respiratory movement change of position. The partial torsion of the jejun was insufficient to explain the clinical sympto Probably the irritation caused by the fish-bone led excessive intestinal contraction, which produced tors of the jejunum proximal to the fish-bone, forcing through the wall of the bowel. Peritonitis follow penetration of the wall of the bowel was proba prevented by the thick end of the fish-bone acting a plug.

I wish to thank Mr. R. J. Rutherford for permission report this case.

Ashington General Hospital,
Northumberland.
ROMAN REJTHAR

FOREIGN BODIES IN THE ABDOMEN

SIR,—The following case, which was admitted to h pital under my care a week ago, is of interest in view the article of Sept. 10 by Mr. Travers and subseque correspondence.

The patient, a man, aged 49, gave a history of sudd onset of severe pain in the upper abdomen the previous aft noon. He had vomited several times during the night, wh the pain became less severe and shifted to the right of t umbilicus. On admission he did not appear to be very i and he had only slight pain. He complained of nausea b had not vomited for some hours. He had had an appendicectomy six years previously, and there was a scar of a rig paramedian incision, through which drainage had obvious been effected. He thought his appendix had perforat at the time of operation. There was some guarding of t right rectus muscle, and tenderness to the right of t umbilicus. A provisional diagnosis of subacute obstructi in the region of the terminal ileum was made.

On opening the abdomen, the intestines were cover by omentum, and when this was moved to one side son turbid fluid escaped. A hand was inserted into the abdomin cavity, and a loop of small intestine was grasped between th finger and thumb, when a sharp prick was felt in both fing and thumb. When drawn from the abdomen, the loop prove to be terminal ileum. Two small perforations, one on eac side of the bowel, were seen, and a foreign body could b palpated inside the bowel. A small incision was made and the foreign body withdrawn. The perforations wer oversewn and the abdomen closed without drainage. H convalescence has been uneventful.

The foreign body proved to be a diamond-shaped piec of beef-bone, $1^{1}/_{4}$ in. long and $^{1}/_{3}$ in. wide at its wides

HYPERSPLENISM WITH ARTHRITIS

SIR,—Dr. Gauld commences his interesting article of ov. 26 as follows: "Hypersplenism was first described y Wiseman and Doan (1939, 1942)." But the term hypersplenism" was certainly in use by Naegeli, d perhaps other hæmatologists on the Continent, bout 1929. Otherwise I could not have written the llowing in 1929[1]:

> 'In regard to the functional activity of the spleen it will probably become more and more convenient to speak of *hypersplenism* and *hyposplenism*—by analogy with the terms *hyperthyroidism* and *hypothyroidism*, *hyperpituitarism* and *hypopituitarism*. It will probably also be found that there are various forms of hypersplenism and hyposplenism corresponding to involvement of the various functions of the spleen (and reticulo-endothelial system), apart from the now well-recognised function of the spleen as a blood-reservoir (Barcroft, &c.)."

his explains the idea of there being various "selective ypersplenisms"—a subject which has been so well orked out by Wiseman and Doan and other modern riters and supported by their clinical observations. any observations are, as Dr. Gauld points out, still quired to throw light on, and confirm, doubtful points.

F. PARKES WEBER.

THE FIRST MEDICAL EXAMINATION

SIR,—As chairman of the biology examiners for the st M.B. examination of the University of London, I ould like to comment on the article by Dr. Johnson your issue of Sept. 17.

It is curious that Dr. Johnson should think that the rpose of the first M.B. examination is to select appropriate students for a medical career. Surely mere selec- on is not the purpose of this or any other examination. n examination is a test of a student's knowledge in a rticular subject, and it is the examiners' sole duty to e that the student has attained a sufficient standard. the first M.B. examination, this standard is an adequate owledge of chemistry, physics, and biology—the basic ences on which his future medical studies depend. he examination gives the student the opportunity to ow his intelligence, but intelligence without knowledge ill not let a candidate through any examination; this rely applies equally to later examinations in a medical dent's course. Therefore the selective action of an amination is only incidental.

It is widely believed that the external first M.B. amination is competitive, but this belief is completely lse. Theoretically it is possible for all candidates to ss or for all to fail. Unfortunately too high a percentage il to reach the requisite standard. The fault for this s in many instances not in the intelligence of the udents but in the inadequacy of the training. especially schools. Dr. Johnson would have done well to note o the figures of passes among *internal students*, who ave studied at the various colleges and medical schools f the university. Here the usual pass percentage is in he neighbourhood of 60% and is often higher. but these tudents have had the benefit of pursuing a course of raining under experienced teachers and in laboratories ith good facilities for practical work. In schools, on he other hand, usually only one or two students are aiming at a medical career, and they have to be included in the same class with other students whose aims are different. The school teacher therefore has to devise a course which will more or less suit all his students, which is often unsatisfactory for all. Furthermore, the facilities for practical work are often inadequate and the time limited; for many school-children preparing for first M.B. (and Higher Certificate too) are not allowed to concentrate on the particular subjects for their examination, but also have to continue with other school subjects simultaneously.

It is not in the least surprising that selection by the University College board and "selection" by the first M.B. examination do not agree; the two tests have different objects and different standards, and apply different methods. One is intended to determine whether a student has reached a certain standard of knowledge in certain subjects; the other is an attempt to estimate, from a less definite basis and by more intangible standards, a student's intelligence and potentialities. It would be unexpected if there was agreement between the two results.

London, W.1.

C. C. HENTSCHEL.

STATUS OF THE PSYCHIATRIC SOCIAL WORKER

SIR,—The liberal attitude which your journal has always maintained prompts me to write to you on this matter.

It is of considerable concern to many of us in the psychiatric service that the vacancies for psychiatric social workers are so many and the candidates so few. It is of even more concern that the salary-scales for these extremely arduous posts are quite inadequate. The Association of Psychiatric Social Workers has, to its great credit, refused to lower the standard demanded of all entrants, and to those of us who work with these valuable colleagues that is a matter for congratulation and due thankfulness. But, Sir, I submit that these officers are seriously underpaid; and that the periods of leave granted to them annually are inadequate for anyone who pursues such an arduous and exacting profession. I suspect that these matters have been the subject of inquiry, and it would be interesting to know the fate of the results of any such inquiry, and any recommendations made by the appropriate committee.

I feel sure, Sir, that any suggestion that the status of the psychiatric social worker shall be raised by increase in salary-scale would be supported by my fellow psychiatrists.

TRANSIENT SPIROCHÆTÆMIA AND SPIRILLÆMIA AFTER DENTAL EXTRACTIONS

SIR,—In their very interesting article of Oct. 1, Dr. McEntegart and Dr. Porterfield contribute to the knowledge of transient invasion of the blood-stream by bacteria from the mouth as a result of dental extraction. Several workers have investigated the problem of bacteræmia following removal of teeth, but we have so far not been able to find any work on transient spirochætæmia, spirillæmia, or viræmia following such operations.

Clinical evidence speaks strongly in favour of such a possibility. We have observed several cases of acute spirochætal (non-syphilitic) or spirillar cystitis following the extraction of decayed or damaged teeth.[1] We have seen others where the bladder disease was found to be of this nature, dental foci were sought, and diseased teeth removed with precautions in order to search for spirochætes in the apical focus and around the roots;

---

[1] *Brit. med. J.* 1929, i, 766.

[1] Coutts, W. E., Vargas-Zalazar, R. *Brit. med. J.* 1946, ii, 982. Coutts, W. E. *Rev. Soc. chile. Urol.* 1947, 10, 175. Coutts, W. E. *Brit. J. ven. Dis.* 1948, 24, 109.

and in these cases we have invariably found, on dark-ground examination, that organisms resembling *Spirochæta dentium* were present—a finding noted in certain dental diseases by Cavalié and Mandoul,[2] Kritchewski and Séguin,[3] and Gins [4] among others. Probably many more cases escape diagnosis because we do not usually ask our patients if they have recently been having, or are having, dental treatment. In some instances we have discovered transient urinary excretion of spirochætes in catheter specimens from both bladder and ureter, in symptom-free patients after removal at one session of several diseased teeth.

All these facts can, in my opinion, only be attributed to transient spirochætæmia or spirillæmia. Who knows that further investigation might not help us to explain many of the symptoms attributed to focal infections of dental origin ?

Santiago, Chile. W. E. COUTTS.

DEOXYCORTONE ACETATE AND ASCORBIC ACID IN RHEUMATOID ARTHRITIS

SIR,—Since the preliminary report by Lewin and Wassén published on Nov. 26, I have treated 10 established cases of rheumatoid arthritis ; 6 have had two injections of deoxycortone acetate and ascorbic acid at weekly intervals, while the other 4 have had only one. Six further cases of rheumatic disease, not classified as rheumatoid arthritis, also received the same treatment.

At this stage I should not have felt justified in making a report, but my experience is so vastly different from that recorded by Dr. Kellgren last week that I feel impelled to communicate the results so that physicians interested in this form of therapy should not be too greatly discouraged by his report. In no single case of rheumatoid arthritis has there been no response whatever to the treatment ; and in some of the cases the response has been almost as startling as those noted in the reports on 'Cortisone' and adrenocorticotropic hormone. Patients who were able only to walk with crutches succeeded in walking unaided within a few minutes of the treatment. The degree and length of improvement varied in different patients. Most patients agree that the immediate improvement was not maintained at the same level after the first 24–48 hours, but all except one assert that they were much better for the rest of the week than they had been for considerable periods of time, ranging from three months to two years.

In those patients who received two injections, the immediate response to treatment with the second injection was just as remarkable as with the first, except for the one case mentioned above. The six non-rheumatoid-arthritis cases showed little or no improvement and two were worse.

It seems at first sight incredible that the same materials used on the same kind of disease in two places not more than two hundred miles apart should provide such contrasting results. Perhaps the answer may lie in the circumstances surrounding the patients undergoing treatment. Dr. Kellgren had his patients in hospital, where presumably they were rested and treated under optimal conditions and were, as he suggests, in a stable condition—i.e., one may assume that they had the minimum of pain with the maximum of movement that their condition allowed. In my cases the patients were ambulatory in varying degrees, with or without crutches, and unable to take proper rest, or indeed to have any form of treatment beyond that which I had been giving them up to the date of these new injections. Their improvement therefore might be interpreted as a physiological response to the hormone used, whereas the condition of Kellgren's cases had already reached this physiological stability and could not gain—and indeed be made worse—by the introduction 'c hormone.

The problem of rheumatic disease is far too co to discuss in a letter, but I think it is reasonably ol to physicians studying arthritis that the end element is only one factor in the problem. In rheum arthritis it is undoubtedly the dominant factor, bu improvement obtained with this form of trea must of necessity be limited in its degree. diligently studying the effects of treatment in cases, we must not lose sight of the fact that perm or complete cure cannot be expected by hormone ment alone ; and, if used injudiciously, it may aggr rather than cure the condition.

Might I suggest to Dr. Kellgren that he should his experiments on some of his outpatients living much less favourable conditions than the Manc Royal Infirmary offers, before finally deciding a the efficacy of this treatment ?

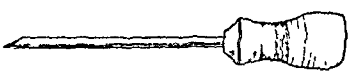
A further point which may be remarked upon is the remedy can hardly be classed as expensive, sinc retail price of one combined injection is rather less 7*s.* 6*d.* ; and no doubt this could be greatly red particularly where, as seems probable both from Lewin and Wassén report and my own very experience, smaller doses achieve the same result.

I should not like to close this letter without reco the great pleasure—albeit with some mental rese experienced by myself and some of my colleagues witnessed the astonishment and joy on the faces o patients who were able to perform acts of locom of which they were previously incapable.

London, W.1. WILLIAM W. F

INTRAVENOUS CANNULA

SIR,—The ingenious cannula-needle described Dr. Ellis (Oct. 15) invites comment. A very number of needles have been invented for intrave therapy and for each a number of advantages have enumerated.



The insertion of a needle into the vein is an opera of precision, and no invention has so far been to dispense with technician's skill facilitated one naturally adept. my opinion the best cannula is the simple nee no. 20 S.W.G., fitted to a standard mount, shown in accompanying figure.

But to obtain satisfactory results attention must directed to the finer details in technique :

1. *The recipient vein must not be button-holed.*—The cu veins are only used in exceptional circumstances ; the fore veins are nearly always accessible. Much greater contr possible with a syringe attached to the needle. Injury to vein by a sudden thrust is avoided by first inserting the ne along the side of the vein ; the needle is withdrawn parti and the point then "felt" through the vein wall.

2. *The needle must lie in the vein correctly.*—After its has entered the lumen of the vein, and whilst the veins kept distended with the manometer, the needle is advan gently and as far as possible.

3. *The needle must be fixed in position.*—Adhesive strapp in direct contact with the needle, without interposed ga fixes the needle so that no movement of its point within vein is possible. Added security may be obtained by usin splint. The operator himself must make himself respons for fixing the needle, since he alone knows the direction the vein and the position of the needle tip.

Such technique renders the Ellis cannula-needle a all other similar inventions unnecessary. The transfus can be set up in a few minutes, and as a rule will conti to run just so long as precautions are taken to ens that the drip is indeed continuous and not intermitt

CEREBRAL PALSY

ir,—I was very interested to read the article by Agassiz, Dr. O'Donnell, and Mrs. Collis in your e of Dec. 3. I do not feel, however, that the differentia- i of cerebral palsy from mental retardation can be le on several of the features which they suggest: et the differentiation can be one of extreme difficulty. mentally retarded infant is retarded in all fields development. It is therefore retarded in social aviour, and it is incorrect to say that a retarded at smiles early. He is retarded in all forms of motor elopment, and therefore shows many of the features ch the writers describe as characteristic, or at least gestive, of cerebral palsy. He is likely to be late in ag the reflexes and involuntary movements of early ncy—the reflex crawling, walking, and swimming ements, the Moro, tonic-neck, and grasp reflexes, the reciprocal kick. He is late in developing head trol, in straightening his back in the sitting position, learning to sit, stand, pull himself to the standing ition, roll, crawl, creep, and so on. He is late in nipulative behaviour and so in holding objects placed his hand, and later in going for objects and grasping m voluntarily, and later still in finer manipulation, h as finger-thumb apposition. Since he is late in owing with his eyes and turning his head to the rce of sound, he is commonly thought to be blind leaf. He is liable to have feeding difficulties, such as k of interest in food, or marked slowness in suckling. ther is dribbling a reliable guide. In the first place ormal infant slobbers until somewhere between a r and eighteen months. In the second place, a rded infant may be just as late as a case of cerebral y in the inhibition of dribbling. It is true that a y with cerebral palsy will be late in approximating lips tightly to his mother's or bottle's teat, so that k escapes during suckling, but so will the retarded l. None of those features, therefore, distinguish tarded child from the child with cerebral palsy.

n a minor degree of cerebral palsy, such as a mono- ia, as I think the writers imply, there may be none these features, the only abnormality noted being ness of one limb during dressing or bathing, or ormality of the pattern of movement in that limb n the child is kicking his legs and waving his arms nt in the wakeful state, or when he is going for an ct. In other cases, in which the spasticity affects ost solely the lower limbs, there is very little or no rdation in manipulative or social behaviour—immediately distinguishing the mentally retarded d who is late in all fields of behaviour.

is only in the severe case that the differentiation ally difficult, because, as the writers say, the child severe cerebral palsy is retarded in almost all s of development. It may still be possible, however, istinguish the two by the social responsiveness of the bral palsy (bearing in mind the mechanical difficulty smiling and vocalisation), the perseverance and centration on a task, such as picking an object up, eagerness and determination to reach it, and the ious satisfaction when it is placed in his hands. has to judge the child more by his intention than his achievement of the act. A normal child is able grasp an object a relatively short time (6–8 weeks) r he has first shown his desire to reach it (after he "grasped it with his eyes," as Gesell says). A arded child is late in showing interest in reaching objects, displays very little concentration and severance, and is late in achieving the act. A child h cerebral palsy may show interest early, but many ks may go by before he grasps an object. A careful erver can detect this intention and desire to grasp g before the child can achieve the act.

One important early sign of cerebral palsy is the intensity of the grasp seen in the flexion of hands and toes. The hand may be so tightly clenched that the finger-nails make the palm of the hand bleed. In a normal baby the hands lie open or only loosely closed by the age of 12 weeks: in a case of cerebral palsy affecting the hands they lie clenched long after that. Another and vitally important sign is the abnormal pattern of movement, not necessarily athetotic. This may be noticed when the child is kicking his legs and waving his arms, but it is much more likely to be noticed when the child is grasping an object: the slow opening of the hand, and the approach to the object with dorsiflexed wrist and extended fingers, is characteristic, and recognised early by one conversant with the normal. The retarded child does not show this abnormal pattern.

Other signs of cerebral palsy, such as adductor spasm in the thigh muscles, resistance in supination of forearms, and resistance to dorsiflexion of feet with extended knees, are naturally looked for.

I would like to add that by far the best articles which I know on the subject of the early diagnosis of both mental defect and cerebral palsy are in Gesell and Amatruda's *Developmental Diagnosis* (London, 1947).

CURARE AND PRECIPITATE LABOUR

Sir,—With regard to Dr. Nosworthy's letter of Nov. 26, my clinical impression—confirmed by an obstetric colleague—is that the increase in the tone of the pregnant uterus is much greater when curare and cyclopropane are used together than when cyclopropane is used alone. In some cases of cæsarean section where curare has been used, the increase in uterine tone has been so marked as to cause temporary embarrassment to the surgeon, and in consequence some surgeons have abandoned the routine injection of 'Pituitrin' into the uterus in these cases. That cyclopropane alone can increase uterine tone there is little doubt, but it would appear that in this respect curare is the chief offender. In view, however, of Mr. Mills's contention (Dec. 10) that curare by itself does not produce strong contractions of the pregnant uterine muscle, it would be interesting to have the views of other anæsthetists and obstetricians.

Scunthorpe, Lincs.

W. N. Rollason.

B.C.G. VACCINATION

Sir,—It was with pleasure that I read the letter from Mr. Francis in your issue of Dec. 10 (p. 1105), for it seems that while we differ in what is relatively inessential we are wholly in agreement on the essential. He confirms my view that in the particular study of B.C.G. vaccination that I criticised there were, in fact, differences between the vaccinated and control groups. He believes that these differences are unimportant; I, naturally enough, need statistical evidence to satisfy me—a full statistical analysis is the essence of a satisfactory trial. But that difference of opinion over one item from the past is unimportant in comparison with the question of the future. Mr. Francis, after obviously wide reading and thought, has reached a conclusion with which I am wholly in agreement. I share his doubts whether "one is justified in carrying out a controlled trial on children or adolescents specially exposed to infection." I share his conviction that "an extensive controlled trial of B.C.G. should be carried out on a section of the general population—i.e., those persons not known to be exposed to special risk." I believe we have the necessary skill and experience to carry out such a trial in this country and I hope we may seize the opportunity before it is too late.

Medicine and the Law

An Unusual Case of Shoplifting

ON Dec. 2, a 24-year-old woman, who admitted having stolen goods to the value of £4 15s. from three London stores, was fined £10 with 5 guineas costs at Great Marlborough Street police-court. On the day in question she had, according to her story, taken some 20–25 mg. of amphetamine sulphate, and a medical witness testified: "In my opinion, if this girl took the number of tablets she claims to have taken, they would induce hilarity and irresponsibility; and she certainly would not realise the effect of what she was doing." Imposing the fine, the magistrate observed: "I would not accept that from you or anybody else. I can see absolutely no connexion between the tablets and a girl going from store to store plundering shopkeepers."

The accused woman, who was reported to be of excellent character, had consulted her doctor on Nov. 21 because of varicose veins; and, since she was overweight, he prescribed 5 mg. amphetamine sulphate ('Benzedrine') three times daily with the object of reducing her appetite. On Nov. 22 and 23 she took the prescribed doses, and she was said to have behaved excitably and to have remarked that the medicine made her feel "very, very happy." On Nov. 24, she apparently took a 5 mg. tablet on rising, 2 further tablets at 10.30 A.M., and either 1 or 2 more (she could not remember which) at 12 NOON; for breakfast she had one slice of toast, and she ate no lunch. In the early afternoon she remarked that she felt as if she were "floating on air." At 4.45 P.M. she was arrested by a woman detective officer, who said that the woman behaved in a very extraordinary way which was compatible with her being under the influence of some drug. On being told that she would be arrested, she laughed heartily and remarked: "Yes, I took them; but it's all a game. It's such fun."

War-time tests of the analeptics, amphetamine[1] and methedrine,[2] showed that a dose of 15 mg. sometimes evokes irresponsible and irrational behaviour, with euphoria, confusion, and excitement. The reaction, which varies between one person and another and in the same person from one occasion to another, is unpredictable from the individual's normal personality.

Parliament

Charge for Prescriptions

WHEN the House of Commons on Dec. 9 accepted the Lords' amendments to the National Health Service (Amendment) Bill,[3] discussion centred on the new clause empowering regulations to be made for charging for pharmaceutical prescriptions. The clause, as Mr. ARTHUR BLENKINSOP, parliamentary secretary to the Ministry of Health, pointed out, is drafted widely because the exact nature of the arrangements have not yet been settled. Discussions are still proceeding, but Mr. Blenkinsop repeated the assurance that old-age pensioners and ex-Service war pensioners would be relieved of the charge.

Mr. WALTER ELLIOT said that the Opposition did not propose to divide against the amendment, but he asked some cogent questions: when would the regulations be laid before Parliament; would the charge be based on each prescription or on each prescription form; would a flat rate or a graded rate be charged?

Dr. SANTO JEGER feared that the charge would deter the wrong people from going to the doctor, but he added that he might not be so opposed to the step as a general principle if there were adequate exceptions. The Minister had lately spoken of "a cascade of medi being poured down people's throats." But medi were often given as a mental poultice, and one spee even though delivered with the eloquence of Mr. Bev would not alter the mental make-up of the world. Mr. I LINSTEAD, secretary of the Pharmaceutical Soc did not condemn a "pay as you use" proposal o hand, but he did not see why it should be restricted t pharmaceutical service. He contended that Parlia should not be asked to go too far in approving the sc until they knew the details. He also compl that the chemists had not yet been brought into discussions.

Mr. SOMERVILLE HASTINGS wanted to know whe the great Socialist principle of "each according t need" was to be replaced by "each according shilling." He doubted whether neurotic people go to the doctor more often than they need woul deterred by a shilling from the enjoyment of bad he which was perhaps the chief interest of their li It was more likely that the change would deter the mother with young children. Again, the doctor save the pocket of a poor patient, might order a mon supply of medicine instead of a fortnight's. Might this result in more medicine being ordered rather less?

Mr. ANEURIN BEVAN admitted that he did not know all the answers as to how he would use t new powers. Before a practical scheme was worked there would have to be discussions with chemists doctors. The charge itself created no administra difficulties, but the exemptions did. Economy, he tinued, was not achieved by transferring a charge f the State to the individual; a proper economy w more efficient way of giving service. This charge not proposed only in consequence of a demand economy; otherwise why should the charge be m in respect of the [illegible] alone? Exp ence had shown [illegible] of the serv in which the general practitioner was most invol that the greatest load had fallen. Abuse had arisen only on bottled medicine, but on aspirins and banda which the patient could often buy for less than a shil without making a second call on his doctor. T proposal would have met with far greater indigna if there had not been an awareness of abuses. He not suggest that this should be a permanent feat of the health service, and it was only put forward a temporary easement. The estimate of a saving £10 million was based on the assumption that there wo be no exemptions, and the saving would now be redu to the extent of the exemptions.

The regulations would require the negative-resolut procedure, but Mr. Bevan promised that he wo arrange the dates so that before the regulations were operation the House would have an opportunity annul them. There had been already some eviden as a consequence of the publicity given to this asp of the service, of a reduction in the burden on the gene practitioner. Mr. Bevan was convinced that as service developed there would be a growing sense responsibility, and disciplines of this sort would not necessary. Mr. HASTINGS interposed to ask whet this reduction in the abuses might not make it unnecess to introduce these regulations. Mr. BEVAN replied t he was considering the possibility, for he was not anxi to burden himself with a complicated administrat machine if he could achieve the results by other mea The motion to agree with the Lords' amendment w carried by 138 votes to 9.

Adoption of Children

ON Dec. 5 the House of Commons considered t Lords' amendments to this private member's bill wh Mr. Basil Nield introduced earlier this year.[4] It is oft desirable to conceal from a natural parent the identi of the prospective adopter, and Mr. K. G. YOUNGE under-secretary of State for the Home Departmen explained that the Bill had tried to meet this difficul by introducing a form of general consent for adoptio The Lords had rejected this proposal on the groun that it was not right to encourage parents to so negle eir responsibility as simply to hand over a child to ybody who might care to adopt it. But they agreed t the actual identity of the adopter need not be closed in all cases. At the third reading of the Bill any members of the House of Commons had expressed e view that there should be greater protection for ospective adopters, but their Lordships were unable accept any proposal that consent to an adoption ould ever become irrevocable before the hearing for e final order. Though the House of Commons rejected e Lords' amendments on these two points, they bstituted a new amendment which Mr. Younger scribed as a reasonable compromise. The provision out concealing the identity of the prospective adopter s altered, and detailed procedure to this end would, r. Younger promised, be provided in Rules. A further bsection provides that once a prospective adopter s made formal application to adopt the child—and he n now do this as early as he likes in the probationary riod—a parent who has given consent to the making an adoption order is not entitled to remove the child om the care of the applicant except with the leave of e court. In considering whether to grant such leave e court is directed to have regard to the welfare of e infant. This provision, Mr. Younger held, should otect the adopter from the " irresponsible snatch-back " the child.

QUESTION TIME

Agenised Flour

Sir **Ernest Graham-Little** asked the Minister of Food what proportion of cases the national flour supplied for tional bread was bleached by the gas known as 'Agene'; ether he was aware of the danger of poisonous effects ing from this gas and that its use had now been forbidden the United States of America; and if he would take similar tion in the provision of our national bread.—Mr. **John rachey** replied: In the year 1948, 95·5% of national ur was treated with agene. As to the second and third rts of the question, I hope to be able to make a statement on on the findings of the scientific committee under the airmanship of Sir Wilson Jameson which has been reviewg the whole question of this and other flour improvers. t I should point out that even in the United States, under e most rigorous tests, agenised flour has not been found have any harmful effect upon human beings.

Maintenance Costs in Glasgow Hospitals

Mr. **James Carmichael** asked the Secretary of State for otland the average weekly maintenance cost per patient the Glasgow Infirmaries, Royal, Western, and Victoria, d in the hospitals, Stobhill, Eastern, and Southern General, ring the years 1947 and 1949, and if he would make a tement on those cases where there had been increases.— . **Arthur Woodburn** replied: I should make it clear at the figures in the appended statement are not on a mparable basis. For example, the 1949 figures include gross cost of nurses' salaries and board and lodging, ereas in 1947 the figures available only include the net cost. re has also been a very substantial increase attributable inly to increases in wages and in the salaries of nurses d other staff and including superannuation charges—which ount to nearly two-thirds of hospital expenditure—and ncreased costs for fuel and light, drugs, and food.

Hospital		*Average weekly maintenance cost per patient*						
		1947				*1949*		
		£	*s.*	*d.*		£	*s.*	*d.*
stern Infirmary, Glasgow	.. ..	10	0	1	..	13	1	11
yal Infirmary, Glasgow	.. ..	7	17	6	..	12	12	7
toria Infirmary, Glasgow	.. ..	9	13	1	..	11	0	6
bhill Hospital, Glasgow	.. ..	4	16	10	..	7	0	7
stern District Hospital, Glasgow	..	4	19	9	..	8	8	0
thern General Hospital, Glasgow	..	4	6	4	..	5	16	8

The figures for 1947 are approximate figures calculated from the ounts of three voluntary hospitals and Glasgow corporation ply by relating total cost to the number of patient-days. The res for 1949 are for the first six months of the present financial ar (April 1 to Sept. 30), and are calculated by a formula which, facilitate comparisons, seeks to eliminate the effect of variations the proportion of unoccupied beds.

The figures for 1949 include not only the cost of board and lodging ovided for resident staff, but also the gross salaries of nurses, out which cash payments in respect of board and lodging are subently received. The 1947 figures include only the net cost of aries and board and lodging. The 1949 figures of cost are thus ated by amounts which may be as much as £1 per week.

National Health Service Prescriptions

Mr. **Philip Piratin** asked whether it was the intention of the Minister of Health to levy charges for prescriptions supplied in hospitals, including those supplied in casualty wards.—Mr. **Arthur Blenkinsop** replied: No.

Mr. **Piratin** asked whether the Minister would publish evidence in his possession disclosing unnecessary resorting to doctors and chemists.—Mr. **Blenkinsop**: No.

Obituary

JOHN ORR

M.D. EDIN., F.R.C.P.E.

Dr. John Orr died in Edinburgh on Nov. 28 at the age of 78.

From George Watson's College he went to Edinburgh University where he graduated M.B. with honours in 1891. In 1894 he gained the M.R.C.P.E. and he was elected a fellow two years later. In the same year he took his M.D. After completing house-appointments at the Edinburgh Royal Infirmary he entered general practice in the south side of the city. He was quickly appreciated as a family doctor, but despite the increasing demands of his practice he found time to take an active part as a teacher in the School of Medicine of the Edinburgh Royal Colleges. As lecturer in materia medica he was an able and popular teacher, and his knowledge of the use of drugs in practice enabled him to present his subject in a practical and interesting manner. In 1925 he was elected dean of the Extra-Mural School, a position he held for 21 years.

His interest in medical education led him to give up general practice over 20 years ago, and between 1930 and 1933 he visited medical schools in Canada, the United States, and India. For many years he represented the Royal College of Physicians of Edinburgh on the board of managers of the Royal Infirmary, where his sound judgment, organising ability, and constant enthusiasm were of great value. Particularly interested in the radiological department as organiser, he watched its development into one of the foremost radiodiagnostic and radiotherapeutic institutions in the country.

A colleague writes: " John Orr was the most approachable of men and he was always willing to help students in difficulty, especially those from abroad. Destitute practitioners and refugee students from Europe, in the days before the war, received much kindly advice and a warm welcome to his hospitable home. But it was not only in medical work that John Orr found outlet for his unbounded energy. An active churchman, he was senior elder in Grange Parish Church. He was twice president of the Watsonian Club and in 1942 he was president of the Scottish Bowling Club. His love of music found practical expression in his services to the Edinburgh Concert Society where for many years he was chairman of the directors. As a tribute to his memory, on Dec. 9 the Scottish Orchestra played Variation No. 9, " Nimrod," from Elgar's *Enigma Variations*. So Edinburgh took farewell of one of her best known and respected citizens, and old students scattered all over the world will remember with affection a beloved teacher and good counsellor."

Dr. Orr is survived by his wife, a son, and two daughters.

LESLIE ALFRED HUMPHREY

M.A., M.B. CAMB., M.R.C.P.

Dr. Leslie Humphrey, who died in University College Hospital on Dec. 1 at the age of 32, was educated at Winchester College and Trinity College, Cambridge, where he took his degree in natural sciences in 1938. After qualifying from University College Hospital in 1944 he held house-appointments at the West Middlesex County Hospital and then trained as a pathologist at Ashford Hospital, Middlesex. In the R.A.M.C., with the rank of major, he was in charge of the command laboratory at the Queen Alexandra Military Hospital, Millbank. In 1946 he took the M.R.C.P. and the following year his M.B.

A friend writes: " His engaging personality and his wide interests and activities made him a charming companion, and his fine character will be a lasting example to those who knew him. He possessed a wisdom beyond his years, which gave him a sympathetic understanding of his colleagues and patients. During his long illness, which he bore with characteristic courage, he maintained his interest in the activities of his friends."

He leaves a widow and two young children.

Mr. WILLIAM ANDERSON

William Anderson approached everyone and everything with an air of confidence and purpose. His patients and assistants could not fail to respond and his work was a pleasure, therefore, to himself and all who were concerned with it. Among his many qualities, one that stood out was his capacity to be on natural terms with anyone in the shortest time. I remember, for example, how he raised shouts of joy from a student audience by telling them : " I had to sit anatomy three times, and I expect it was good for me." The statement was correct, but not in the way his audience understood it ; for his second and third sittings were undertaken to acquire the F.R.C.S., first of Edinburgh and later of London.

He knew everything about how his patients lived and thought. He spoke naturally and quietly in their own dialect about their own affairs to excited folk from the country and took away the strangeness they felt on finding themselves in town and in hospital. I know of his giving up an hour to reassure one patient the night before her operation although he was then in great demand and desperately busy. He was a good disciple of Hippocrates—the patient, always the patient, came first. He could be "richt damned cross" about anything he regarded as professional failure or neglect if it injured the patient. But his reproaches were not made in bitterness and he quickly forgave mistakes, especially if they were admitted and above all if they arose from a willingness to accept responsibility.

He had the qualities that may be regarded as characteristic of the best type of Aberdonian : he was hard-headed and soft-hearted. As consulting surgeon to Scottish Command in the late war he proved himself an expert at reducing tangled situations to their essentials and abating the follies of war-time life with outspoken blasts of good sense, warmly and often humorously expressed. Throughout his life he did a great deal of good quietly, and his surgical interests ranged widely. " At one time I was even the honorary surgeon to the pigs at the Rowett Institute," he liked to remind his colleagues. Wherever he worked he made friends ; wherever he was known the news of his sudden death was received with deep sadness. He showed no outward signs of the strenuous life he had lived and there was every reason to suppose that he still had much to give and much to enjoy. It is our loss and grief that this expectation has been so abruptly proved wrong.

J. W. H.

It came as a great shock to many of his friends in the South to hear of the death of William Anderson, and more particularly to those of us in the Society of Thoracic Surgeons who had met him a few weeks ago in Sheffield. Anderson was one of the founder members of the society and he had always been present at our meetings at home and abroad. He had been a member of the committee from the beginning and in due course was elected president, but he only held office for a year, forgoing a further period so as not to stand in the way of younger men, an attitude that was characteristic. His views, whether on surgery or policy, were honest, sober, and forthright ; in consequence his opinion carried great weight. It was always a joy to have him with us on our visits to the various clinics, more particularly when we went abroad where his cheerful conversation lightened many a long train journey and brightened our evenings. Willie Anderson was better known to us in the South than many of his colleagues north of the border, and he will be greatly missed in our surgical circles by his many friends.

J. B. H.

Many members of the profession will have heard with regret of the death of Mr. A. LISTER HARRISON, who was a member of the board of the *Metropolitan Hospital* and of THE LANCET Commission on Nursing (1932). A nephew of Lord Lister, he was 78 years of age.

Public Health

Undiagnosed Epidemic in Italy

A PECULIAR epidemic infection is reported Stefanutti [1] from the vicinity of Foggia in Italy. onset is sudden, without any prodromal sympt and the illness lasts from two weeks to thirty days. patient, who is always a male, is usually not ill en to take to his bed, although feverish. The fev slight in the first week but higher in the second and weeks, when the temperature reaches 101-1 in the evening, though it is normal in the mor It falls by lysis. When the fever is at its highest are night sweats. The onset is characterised by cata conjunctivitis, which last a fortnight, slight sore th dry cough, anorexia, obstinate constipation, and quency of micturition, with a burning sensation in posterior urethra. There was intense frontonu headache. In at least two cases orchitis develo both testes being affected, *not simultaneously but* an interval of a few days. The testes were sw " to the size of an orange " but were painless. scrotum and spermatic cords appeared normal, swollen glands were found, and nothing abno was found in the urine. Tests for syphilis, ent fever, and Malta fever gave negative results. At time of the orchitis the blood showed slight nor chromic anæmia, a white-cell count of about 10,000 c.mm. (neutrophilia 60–65 %), and slight eosinop (4–6 %).

Poliomyelitis

During the week ended Dec. 3 notifications in Engl and Wales were : poliomyelitis 141 (176), polioence litis 15 (17). Figures for the previous week are sh in parentheses. Multiple cases (poliomyelitis and po encephalitis together) were reported from the *follow* counties :

London 16 (24), Berks 3 (3), Buckingham 2 (5), Chest (6), Essex 7 (16), Gloucester 7 (8). Hertford 2 (6), Kent (14), Lancaster 14 (10), Leicester 3 (7), Middlesex 15 (Norfolk 4 (12), Nottingham 6 (5), Oxford 2 (1), Southam 5 (4), Stafford 5 (3), Surrey 6 (6), Sussex, East 4 (3), War 6 (7), Yorks, *West Riding* 19 (17), Glamorgan 6 (5).

Appointments

BARRON, J. N., M.B. N.Z., F.R.C.S.E. : director, plastic and injury unit, Odstock Hospital, Salisbury.
CHARLTON, E. P. H., M.D. Durh., D.P.M. : consultant psychia and deputy medical superintendent, *Graylingwell* Hosp Chichester.
CRAWSHAW, D. G., M.B. Manc., D.C.H., D.P.H. : M.O.H., Peterboro
DONALDSON, R. J., M.B. Belf., D.P.H. : deputy M.O.H. and de school M.O., Northampton.
DRAPER, R. W., M.B. Edin. : surgical officer (B1), Edenhall Hosp Musselburgh.
HINDE, R. T., F.R.C.S. : asst. ear, nose, and throat surgeon, Ex clinical area.
HUMPHREYS, MAIR, M.B. Lpool : asst. county M.O.H. and school M.O., Anglesey.
LLOYD, T. W., D.M. Oxfd, M.R.C.P. : medical superintendent consultant chest physician, South Worcestershire group hospitals and St. Wulstan's Hospital, Malvern.
MACAULAY, D. B., M.B. Lpool, M.R.C.P. : visiting physician, Bo General Hospital.
ODELL, J. R., M.B. Lond., D.A. : first assistant, anæsthetics de Royal Free Hospital, London.
ROCHE, G. K. T., M.B. Lond., D.A. : consultant anæsthetist, Ro National Orthopædic Hospital, London.
RODGER, WILLIAM, M.B. Glasg., D.P.H. : M.O.H., Coatbridge.
SIMMONS, ERNEST, M.D. Bonn : *consultant* child psychiatr North Wales area.
STANSFIELD, R. N., M.R.C.S. : asst. psychiatrist, Herrison Hosp Dorchester, Dorset.
TIBBETTS, R. W., M.A., B.M. *Oxfd*, D.P.M. : psychiatrist (S.H.M grade), Graylingwell Hospital, Chichester.
WEIR, J. H., M.D., B.HY. Durh., D.P.H. : M.O.H., Kensington a Chelsea.

***Appointed Factory Doctors* under the Factories Acts:**

GEOHEGAN, P. J., M.B. N.U.I. : Crowland district, Lincs.
GILL, J. M. C., M.B. Aberd. : Inverurie district, Aberdeenshire.
HOLMES, E. A., M.R.C.S. : Peterborough district.
PLATTEN, M. C., M.A. Camb., M.B. Birm. : Meriden distri Warwickshire.

Notes and News

HEBERDEN SOCIETY

At a meeting of this society at the Royal College of Surgeons Dec. 10 the following officers for 1950 were elected: presi-it, chairman, and librarian, Dr. W. S. C. Copeman; presi-t-elect, Sir Henry Cohen; treasurer, Dr. Ernest Fletcher; or hon. secretary, Dr. R. M. Mason; junior hon. secretary, F. Dudley Hart. The other members of the executive 'ttee are Dr. Hugh Burt, Dr. E. G. L. Bywaters, Mr. W. D. tart, Dr. G. D. Kersley, Dr. L. G. C. Pugh, and Prof. R. E. bridge. The Heberden oration was delivered by Prof. F. od Jones, F.R.S., who spoke on Classical Gout.

At the annual dinner held at the college the same evening toast of The Guests, proposed by Dr. Mason, drew a nse from Lord Lucas of Chilworth, captain of the King's lyguard of the Yeoman of the Guard. Lord Webb-Johnson, foot from Canada, said that rheumatism was one of the st serious diseases affecting the Commonwealth. Heberden l been one of the great clinicians; but today the art of mining the patient was, he feared, in danger of being lost. e great clinical teaching in the English schools had, he ught, originated in the Irish schools in the days of Graves l Stokes, and Britain still had men who were showing—James Mackenzie showed—how much could be learnt by enthusiasm of a keen observer. Though a visit to America t one envious, it should not be forgotten that the fundantal discoveries had mostly emanated from this country. . Copeman, responding as chairman, said that this annual eeting completed the Heberden Society's 13th year. It ntinued to prosper, and with membership limited to 100 l a long waiting-list. The "Heberden round" had been d at Oxford under the auspices of Prof. L. J. Witts, and xt year new ground would be broken by holding the round Paris on the invitation of Prof. F. Coste, the one and only fessor of rheumatic diseases in the world. The society had en represented at the International Congress on Rheumatic eases held in New York, when Dr. Philip Hench, one of the iety's two honorary members, reported his work on ortisone.' Dr. Copeman concluded by presenting the berden medal to Professor Wood Jones, whom he described the greatest living anatomist, and the medallist very briefly ressed his thanks.

Next day, at St. Thomas's Hospital, Prof. D. V. Davies ned a discussion on Anatomical Aspects of the Rheumatic eases, speaking particularly of the vascular pattern and ve-supply of joints. Dr. W. A. Fell contributed a paper ling with the relation between referred pain and lesions in ferent parts of the joint capsule.

THE RETURN JOURNEY

Boadicea was not the exceptional woman we are apt think her. In her day women were on an equal footing h men, and Caesar himself noted that among the Gauls l Britons no distinction of sex was made in places of nmand or government. In Saxon England women conued to share the rights as well as the responsibilities of n—took part in national and local moots as landowners l burgesses, were largely responsible for the conversion the land to Christianity, and were at the head of many gious houses, ranking just below bishops. In a just but rant book,[1] Miss Ethel M. Wood traces for us the decline the status of women which began with the Norman Conest and reached its nadir in 1832, when the Reform Act prived them finally and legally of the right to vote. Until it time, though the right of women to use the vote had en been challenged, there was no lawful way of preventing em from doing so if they chose; most of them were too pressed to choose. It took nearly a hundred years to win ck that lost political right—years in which a fictitious ture of woman, not as a comrade and counsellor, taking ual responsibility with men, but as a dependent, physically d intellectually, inferior, a modest perpetual parasite, s constantly set before each rising generation of girls. ollope could write of a rich young widow, about to marry ain, "She would give up the heavy burden of her dependence, and once more assume the position of a man . . ."—a position which like a point in geometry d place but no magnitude. What she might do, and what she might not do, were rigidly controlled unless of course she was a working woman—or a lady without means, in which case she became a governess despised by all. In this dark age of frustrate women a few intelligent and sturdy ones saw clearly and broke a way out of prison for the rest. Miss Wood glances at the careers of some of them—Mary Wollstonecraft, Elizabeth Fry, Josephine Butler, Elizabeth Garrett Anderson, Sophia Jex-Blake, Florence Nightingale, and Octavia Hill among them. Fortunately, most of them were long-lived and did a good deal with their time; they needed to be, for in addition to the steady opposition of men (a few liberal minds excepted) they had to contend with the apathy, and even the opposition, of women. It is a strange story, told gaily; and it reminds us that the long fight for fair-dealing is still going on. Women, with great difficulty, won back the franchise; they have not yet recovered the right to equal pay for equal work which they enjoyed in ancient Ireland or the equality of opportunity which the great English trade gilds accorded them.

University of Cambridge

Dr. Leslie Cole, F.R.C.P., senior physician to Addenbrooke's Hospital, has been elected to a supernumerary fellowship at King's College.

University of Bristol

The Carey Coombs prize for 1949 has been awarded to Dr. I. McD. Stewart for an essay on the Ætiology of Coronary Thrombosis.

University of Dublin

On Dec. 8 at the school of physic, Trinity College, the following degrees were conferred:

M.D.—W. E. R. Hackett, F. J. C. Loughran, J. D. McKeever, Irene S. Orgel.

M.B., B.Ch., B.A.O.—J. H. Ashmore, Evelyn Browne, Joan I. Buchanan, L. J. Clein, Margaret B. E. Ellis, E. G. England, R. C. Gray, R. ft. Jackson, Vyvyan I. K. Johnston, O. H. Killen, W. A. McGaw, E. B. McHugh, Sheilagh M. McHugh, W. D. McNaul, T. T. E. Michael, E. V. Page, Ruth M. Perrott, Gwendoline G. L. Poots, W. D. H. Powell, R. N. Siberry, B. A. McC. Thompson F. A. Walkey.

L.M.S.—B. J. O'Reilly.

Royal College of Surgeons of England

At a meeting of the council held on Dec. 8 with Sir Cecil Wakeley, the president, in the chair, Sir Harry Platt was appointed Bradshaw lecturer for 1950. Hunterian professorships were awarded to Prof. Milroy Paul, of Ceylon, and Mr. R. T. Johnson, of Manchester.

Mr. D. N. Matthews was elected a member of the surgical section of the board of examiners in dental surgery, and Mr. C. C. Hentschel an examiner in elementary biology under the Conjoint Board. The following examiners were appointed for the primary fellowship examination to be held in Ceylon, India, and Pakistan: Sir Gordon Gordon-Taylor (anatomy); Prof. Geoffrey Hadfield (pathology), and Prof. A. St. G. Huggett (physiology).

Diplomas of fellowship were granted to the following:

J. L. Reid, G. D. Channell, J. C. Watts, I. A. Donaldson, Raymond
[illegible] Rogers, F. S. Gorrill, F. A. Henley,

CRAWSHAW, D. G., M.B. Manc., D.C.H., D.P.H.: M.O.H., Peterbor

DONALDSON, R. J., M.B. Belf., D.P.H.: deputy M.O.H. and de school M.O., Northampton.

DRAPER, R. W., M.B. Edin.: surgical officer (B1), Edenhall Ho Musselburgh.

HINDE, R. T., F.R.C.S.: asst. ear, nose, and throat surgeon, E clinical area.

HUMPHREYS, MAIR, M.B. Lpool: asst. county M.O.H. and school M.O., Anglesey.

LLOYD, T. W., D.M. Oxfd, M.R.C.P.: medical superintendent consultant chest physician, South Worcestershire grou hospitals and St. Wulstan's Hospital, Malvern.

MACAULAY, D. B., M.B. Lpool, M.R.C.P.: visiting physician, B General Hospital.

ODELL, J. R., M.B. Lond., D.A.: first assistant, anæsthetic d Royal Free Hospital, London.

ROCHE, G. K. T., M.B. Lond., D.A.: consultant anæsthetist, R National Orthopædic Hospital, London.

RODGER, WILLIAM, M.B. Glasg., D.P.H.: M.O.H., Coatbridge.

SIMMONS, ERNEST, M.D. Bonn: consultant child psychiat North Wales area.

STANSFIELD, R. N., M.R.C.S.: asst. psychiatrist, Herrison Hosp Dorchester, Dorset.

TIBBETTS, R. W., M.A., B.M. Oxfd, D.P.M.: psychiatrist (S.H. grade), Graylingwell Hospital, Chichester.

WEIR, J. H., M.D., B.HY. Durh., D.P.H.: M.O.H., Kensington Chelsea.

Appointed Factory Doctors under the Factories Acts:

GEOHEGAN, P. J., M.B. N.U.I.: Crowland district, Lincs.

GILL, J. M. C., M.B. Aberd.: Inverurie district, Aberdeenshire

HOLMES, E. A., M.R.C.S.: Peterborough district.

PLATTEN, M. C., M.A. Camb., M.B. Birm.: Meriden distr Warwickshire.

Notes and News

HEBERDEN SOCIETY

a meeting of this society at the Royal College of Surgeons ·e. 10 the following officers for 1950 were elected: presi- chairman, and librarian, Dr. W. S. C. Copeman; presi- , Sir Henry Cohen; treasurer, Dr. Ernest Fletcher; hon. secretary, Dr. R. M. Mason; junior hon. secretary, . Dudley Hart. The other members of the executive are Dr. Hugh Burt, Dr. E. G. L. Bywaters, Mr. W. D. Dr. G. D. Kersley, Dr. L. G. C. Pugh, and Prof. R. E. ge. The Heberden oration was delivered by Prof. F. Jones, F.R.S., who spoke on Classical Gout.

the annual dinner held at the college the same evening oast of The Guests, proposed by Dr. Mason, drew a from Lord Lucas of Chilworth, captain of the King's of the Yeoman of the Guard. Lord Webb-Johnson, from Canada, said that rheumatism was one of the serious diseases affecting the Commonwealth. Heberden een one of the great clinicians; but today the art of the patient was, he feared, in danger of being lost. reat clinical teaching in the English schools had, he originated in the Irish schools in the days of Graves tokes, and Britain still had men who were showing—mes Mackenzie showed—how much could be learnt by sm of a keen observer. Though a visit to America ne envious, it should not be forgotten that the funda- l discoveries had mostly emanated from this country. opeman, responding as chairman, said that this annual ng completed the Heberden Society's 13th year. It ued to prosper, and with membership limited to 100 long waiting-list. The "Heberden round" had been at Oxford under the auspices of Prof. L. J. Witts, and year new ground would be broken by holding the round is on the invitation of Prof. F. Coste, the one and only sor of rheumatic diseases in the world. The society had represented at the International Congress on Rheumatic es held in New York, when Dr. Philip Hench, one of the y's two honorary members, reported his work on sone.' Dr. Copeman concluded by presenting the den medal to Professor Wood Jones, whom he described greatest living anatomist, and the medallist very briefly ssed his thanks.

t day, at St. Thomas's Hospital, Prof. D. V. Davies d a discussion on Anatomical Aspects of the Rheumatic es, speaking particularly of the vascular pattern and supply of joints. Dr. W. A. Fell contributed a paper g with the relation between referred pain and lesions in nt parts of the joint capsule.

THE RETURN JOURNEY

dicea was not the exceptional woman we are apt nk her. In her day women were on an equal footing nen, and Caesar himself noted that among the Gauls Britons no distinction of sex was made in places of and or government. In Saxon England women con- l to share the rights as well as the responsibilities of -took part in national and local moots as landowners urgesses, were largely responsible for the conversion land to Christianity, and were at the head of many us houses, ranking just below bishops. In a just but nt book,[1] Miss Ethel M. Wood traces for us the decline status of women which began with the Norman Con- and reached its nadir in 1832, when the Reform Act ed them finally and legally of the right to vote. Until ime, though the right of women to use the vote had been challenged, there was no lawful way of preventing from doing so if they chose; most of them were too ssed to choose. It took nearly a hundred years to win that lost political right—years in which a fictitious e of woman, not as a comrade and counsellor, taking responsibility with men, but as a dependent, physically intellectually, inferior, a modest perpetual parasite, constantly set before each rising generation of girls. pe could write of a rich young widow, about to marry , "She would give up the heavy burden of her endence, and once more assume the position of a n . . ."—a position which like a point in geometry lace but no magnitude. What she might do, and what she might not do, were rigidly controlled unless of course she was a working woman—or a lady without means, in which case she became a governess despised by all. In this dark age of frustrate women a few intelligent and sturdy ones saw clearly and broke a way out of prison for the rest. Miss Wood glances at the careers of some of them—Mary Wollstonecraft, Elizabeth Fry, Josephine Butler, Elizabeth Garrett Anderson, Sophia Jex-Blake, Florence Nightingale, and Octavia Hill among them. Fortunately, most of them were long-lived and did a good deal with their time; they needed to be, for in addition to the steady opposition of men (a few liberal minds excepted) they had to contend with the apathy, and even the opposition, of women. It is a strange story, told gaily; and it reminds us that the long fight for fair-dealing is still going on. Women, with great difficulty, won back the franchise; they have not yet recovered the right to equal pay for equal work which they enjoyed in ancient Ireland or the equality of opportunity which the great English trade gilds accorded them.

University of Cambridge

Dr. Leslie Cole, F.R.C.P., senior physician to Addenbrooke's Hospital, has been elected to a supernumerary fellowship at King's College.

University of Bristol

The Carey Coombs prize for 1949 has been awarded to Dr. I. McD. Stewart for an essay on the Ætiology of Coronary Thrombosis.

University of Dublin

On Dec. 8 at the school of physic, Trinity College, the following degrees were conferred:

M.D.—W. E. R. Hackett, F. J. C. Loughran, J. D. McKeever, Irene S. Orgel.

M.B., B.Ch., B.A.O.—J. H. Ashmore, Evelyn Browne, Joan I. Buchanan, L. J. Clein, Margaret B. E. Ellis, E. G. England, R. C. Gray, R. ff. Jackson, Vyvyan I. K. Johnston, O. H. Killen, W. A. McGaw, E. B. McHugh, Sheilagh M. McHugh, W. D. McNaul, T. T. E. Michael, E. V. Page, Ruth M. Perrott, Gwendoline G. L. Poots, W. D. H. Powell, R. N. Siberry, B. A. McC. Thompson F. A. Walkey.

L.M.S.—B. J. O'Reilly.

Royal College of Surgeons of England

At a meeting of the council held on Dec. 8 with Sir Cecil Wakeley, the president, in the chair, Sir Harry Platt was appointed Bradshaw lecturer for 1950. Hunterian professorships were awarded to Prof. Milroy Paul, of Ceylon, and Mr. R. T. Johnson, of Manchester.

Mr. D. N. Matthews was elected a member of the surgical section of the board of examiners in dental surgery, and Mr. C. C. Hentschel an examiner in elementary biology under the Conjoint Board. The following examiners were appointed for the primary fellowship examination to be held in Ceylon, India, and Pakistan: Sir Gordon Gordon-Taylor (anatomy); Prof. Geoffrey Hadfield (pathology), and Prof. A. St. G. Huggett (physiology).

Diplomas of fellowship were granted to the following:

J. L. Reid, G. D. Channell, J. C. Watts, I. A. Donaldson, Raymond Ramsay, Bernard Fairburn, N. C. Rogers, F. S. Gorrill, F. A. Henley, Sundram Pillai, L. A. Atkinson, R. C. Jack, D. O. Williams, J. S. Tomkinson, A. E. Howarth, H. A. Ripman, D. A. Langley, M. G. Wilson, J. P. Mitchell, D. L. Evans, M. P. Durham, J. W. Betts, F. T. Graves, G. S. Ramsay, F. R. Sutton, D. A. T. Farrar, B. H. Hand, D. W. Thomas, M. O. Carruthers, Keith Chitty, B. V. Jones, R. W. Tudor, V. S. Brookes, D. A. C. Reid, Austin Brown, A. W. Nurick, I. P. Todd, I. B. Smith, J. S. R. Golding, A. M. H. Bennett, N. J. Blockey, A. G. Dingley, P. N. Robson, J. F. Bolton Carter, M. C. T. Reilly, Charles Taylor, Rashed Iskander, Mahmoud Ahmed Radwan, A. J. Clyne, W. W. Davey, Man Mohan Nath, Marjorie A. Powys, S. A. Bond, J. N. Appleton, W. M. Manchester, Bekhit Mohammed Omar, T. G. Barlow, R. D. Condon, H. H. Gilbert, Hussni El Sayed Higazi, Gurijala Pattabhi Ramayya, T. G. Cameron, W. W. Hallwright, Lansell Bonnin, R. R. Dickson, P. H. Greenwell, J. S. Guest, Leslie Jayasuriya, R. C. R. Loane, A. F. Murphy, E. R. W. Thomson, A. J. Alldred, Joseph Block, P. W. Cotter, Charles Dundon, R. C. Evans, B. P. Flannery, F. E. J. Gabel, A. J. Gunning, G. F. T. W. Henson, T. P. Morley, Roshun Patuck, Anthony Roper, M. I. Symonds, Derek Ainslie, Allan Clain, P. R. R. Clarke, Chandra Pal de Fonseka, John Hewet, D. A. Macfarlane, A. B. Mackenzie, W. J. McLaren, I. W. MacPhee, T. H. L. Rosser, C. L. Tucker, L. S. Walsh, J. A. Baird, H. D. W. Black, A. F. Bromwich, M. F. Butler, J. F. Dark, N. C. Davis, J. D. K. Dawes, W. R. Lang, W. A. Liddell, Nanalal Jivan Shah, D. B. Caro, D. H. Keller, D. N. Ross, A. G. Parks.

Hospital Festivities at Christmas

An Exchequer contribution towards the cost of these festivities at the rate of 5s. per head of patients and resident staff has been authorised again this year.

Royal College of Physicians of Edinburgh

At a meeting of the college held on Dec. 1, Sir David Henderson was elected president for the ensuing year. The following were elected to be members of council: Dr. W. A. Alexander, Dr. J. D. S. Cameron, Dr. T. Douglas Inch, Dr. Ian G. W. Hill, Dr. James G. M. Hamilton, and Dr. A. Colin P. Campbell. Dr. Alexander was nominated vice-president.

Editorship of the J.A.M.A.

Dr. Austin Smith is reported by B.U.P. to have succeeded on Dec. 6 to this appointment, from which Dr. Morris Fishbein retired on Dec. 1.

Institute of Child Health

Dr. T. P. Mann has been appointed assistant to the professor of child health at the *Institute of Child Health, University* of London, for work in the newborn-baby department at the Postgraduate Medical School of London.

British Association of Physical Medicine

A course of lectures for candidates preparing for part II of the diploma in physical medicine will be held on Tuesdays and Thursdays, from Jan. 3 to Feb. 9, at 5 P.M. Further details can be had from the honorary secretary of the association, 45, Lincoln's Inn Fields, London, W.C.2.

London School of Hygiene & Tropical Medicine

Prof. N. H. Swellengrebel, director of the department of tropical hygiene at the Royal Institute for the Indies, Amsterdam, will give two lectures in January at the school, Keppel Street, W.C.1. On Tuesday, 17th, he will speak on Plague in Java, and on Wednesday, 18th, on How the Malaria Service in Indonesia Came into Being. Both lectures will be held at 2 P.M.

Congress on Criminology

The second International Congress on Criminology is to be held in Paris from Sept. 7 to 14, under the presidency of Prof. Donnedieu de Vabres. The representatives for the United Kingdom are Dr. Denis Carroll and Mr. Hermann Mannheim, DR. JURIS. Further particulars may be had from the organising secretary, c/o Institute for the Scientific Treatment of Delinquency, 8, Bourdon Street, London, W.1.

Form E.C.1 *(Revised)*

To reduce *inflation of doctors' lists in the registers of* executive councils, a revised form E.C.1 is to be introduced on Jan. 1. This revised form can be used either for a first application to be placed on a doctor's list or for transfer to another doctor when the medical card is missing. Supplies of the form will be obtainable only at executive-council offices and doctors' surgeries, and (on the *registration of a birth) from* the registrar of births.

Mr. Ewing on the National Health Service

Mr. Oscar R. Ewing, United States federal security administrator, and author of the Ewing report on *The Nation's Health* (see *Lancet*, 1948, ii, 574), spent last week in London, where he saw the Prime Minister and other members of the Government as well as others concerned with health, education, and social insurance. At a press conference on Friday, reported in the *Times*, he spoke of President Truman's request to Congress to enact a national health insurance programme to cover all citizens. "I can now see that most of the critics of our proposal in the United States have, whether deliberately or through ignorance, tried to mislead the American people on the facts about the British programme. It seems to me that this programme is working remarkably well, and that it is a good thing for Britain. This is what we have been told by people representing all shades of political opinion, as well as by most of the physicians with whom we have talked." He had, he added, been horrified to learn that "certain groups in organised American medicine who are opposing health *insurance* in the United States have been contributing financially to support the propaganda activities of a small group of die-hard British doctors still fighting the health programme here." He regarded this as unfair and dangerous interference.

Mr. Ewing and his associates have since been to Eire and Scotland, and are going on to Sweden, Switzerland, Italy, and Israel.

International Hæmophilia Society

A general meeting of the society will be held at the Soci for Visiting Scientists, 5, Old *Burlington Street*, Piccadi London, S.W.1, *on* Sunday, Dec. 18, at 2.30–5 P.M. Doct and hæmophilics or their representatives are invited to atte Communications should be *addressed to the society* the Galton Laboratory, University College, Gower Str London, W.C.1.

Liverpool Regional Hospital Board

At a meeting on Dec. 1 this board agreed that as a lo term policy sufficient accommodation should be provided obstetric units for at least three-quarters of the births in region, and that in gynæcological units ample provis should be made for cases of abortion. The board also approv in principle a recommendation by the Chester and dist hospital management committee that maternity accommo tion in the Runcorn area should be made available to gene practitioners.

The board considered a request by the faculty of medic of the university that opportunities should be afforded sixth-year students to see emergency work in hospita and the board have decided that in the first instance facilit should be afforded for students to see emergency operatic *at four hospitals in the region.*

A verbatim report of the Second Commonwealth a Empire Health and Tuberculosis Conference, held in Lond last July, has been published by the National Associati for the Prevention of Tuberculosis. Copies (15*s*. *each*) m be obtained from the association, Tavistock House Nort Tavistock Square, London, W.C.1.

The Central Council for District Nursing in London ha revised their Directory of District Nursing and Streets Lis for London. Copies, price 3*s*. each, may be had *from* t council, 25, Cockspur Street, London, S.W.1.

Diary of the Week

DEC. 18–24

Tuesday, 20th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
3.45 P.M. Mr. R. J. Last: The Larynx. (Arnott *demonstration*

Problems in Renal Diseas

Births, Marriages, and Deaths

BIRTHS

ANDREW.—On Dec. 8, in Manchester, the wife of Dr. S. S. Andre —a daughter.

BURSLEM.—On Nov. 30, in Chester, the wife of Dr. R. W. Burslem— a son.

HOVENDEN.—On Dec. 5, the wife of Dr. Geoffrey Hovenden— daughter.

MORRIS.—On Dec. 3, in Dublin, the wife of *Dr. L. E.* Morris— a daughter.

NIGHTINGALE.—On Dec. 8, the wife of Dr. J. A. Nightingale— *daughter.*

PRITCHARD.—On Dec. 6, the wife of Dr. John Pritchard—*a daughte*

RICKFORD.—On Dec. 4, in London, the wife *of Mr. Braithwait* Rickford, F.R.C.S.—a son.

DEATHS

JONES.—On Dec. 5, at Rhyl, Edward Hugh Jones, M.D., C.M. Edin. aged 81.

JONES.—On Dec. 3, in *Manchester*, John Grant Jones, M.D. *Aberd.* *aged* 77.

MACFAUL.—*On Dec.* 7, *at* Leigh, Lancs, Alexander MacFaul, M.B. Belf.

MCKINSTRY.—On Dec. 7, William Kilbourn McKinstry, M.A. Camb., M.R.C.S., aged 50.

MUNRO.—On Dec. 8, in *London*, Hector Munro, M.B. *Aberd.*

OGG.—On Dec. 5, in London, Theodore *Alexander* William Ogg, M.D. Lausanne.

RUSSELL.—On Dec. 6, at Crowborough, Sir Michael Russell, K.C.M.G., C.B., M.R.C.S., aged 89.

FAMILY DOCTOR

IMPACT OF MODERN THERAPEUTIC IDEAS ON GENERAL PRACTICE *

R. J. PERRING
M.D. Durh.

PIRATION to the art of healing is as old as the ry of man, but it is only within the last hundred s or so that the first tentative shoots of modern cal science have burst through the superstition and ricism remaining from medieval times—an age when profession thought it better for a patient to die rding to the rules than to live by violating them. 1849 the foundations of anatomy and pathology been well laid, but the great names of Louis Pasteur Joseph Lister (and all they stood for) were as yet own in the land. Medical practitioners still shambled trotted along the old paths, dividing themselves rding to their fancy into either "strengtheners" or rerers," for the heroic times of copious bleeding blistering had not yet departed. It was not until that the Medical Act transferred to the General ical Council the responsibility of deciding who should rmitted to practise. Hitherto the high standard up to the public mind by the Royal College of sicians had not prevented quackery from having xcellent time of it: for, since professional practice isted mainly in the administration of a great many s. the public inferred that they might be better with more drugs still, if these could be got cheap ch. and therefore swallowed large cubic measures hysic prescribed by unscrupulous ignorance which taken no degrees. In 1878 George Eliot could still e:

> "With our present medical rules and education, one st be satisfied now and then to meet with a fair prac- ner. As to the higher questions which determine the rting point of a diagnosis—as to the philosophy of dical evidence—any glimmering of these can only come m a scientific culture of which country practitioners ve no more notion than the man in the moon."

medical man was still on the lower rungs of the social er. To quote from the same author:

> "I prefer a medical man more on a footing with the vants. They are often all the cleverer. I assure you found my old doctor's judgment unfailing. He was rse and butcherlike but he knew my constitution."

e latter half of the 19th century was, of course, great age of Victorian industrialism. Labour from countryside, tempted by the relatively large wages, d into the already swollen towns, bringing with it wn quota of disease. Preventive medicine was only s infancy, and contamination of water-supplies, crowding, too long working hours, and an ill-adapted ry brought increasing toil to the ill-equipped prac- ter. But in the end the human conscience and an intelligence gradually overcame the inertia of rvatism and ignorance. And as decade followed de it became obvious that, without outside assistance, family doctor could no longer supply the needs of patient; for these now included laboratory tests hemical and bacteriological), radiography, and other ialised non-clinical services. As the health of the munity is a national asset, it became obvious that e devolved upon the State the duty of providing cal attention on a large scale. The National Health rance Act of 1911 was the first step in this direction. the Ministry of Health, set up in 1919, interpreted more widely the responsibility of a government for health and well-being of its citizens.

Here then is the first application in a large way of the principle of economic security as a therapeutic agent. Since these now far-off days the social conscience has been still further stimulated, and we are now launched for better or worse upon the full-scale programme of the National Health Service. Whether this will oust the family doctor from his valued place in the community depends, in my opinion, first and last upon the man himself.

CHANGES IN DISEASE

My purpose here is to recall some of the great changes in the practice of medicine which have occurred in my own experience—i.e., within the last 28 years.

It is a most surprising thing that in the 1916 edition of Osler's *Principles and Practice of Medicine*, the book from which I originally learnt my medicine, there is no mention of the word "vitamin." The ætiology of so common a disease as rickets hung insecurely upon such vague and insubstantial pegs as poor feeding, lack of sunlight, bad ventilation, and faulty assimilation of lime salts. By the early 1920s, however, knowledge of the accessory food factors had widened. Vitamin D had been differentiated from vitamin A and later synthesised by the irradiation of ergosterol. I have not seen a case of florid rickets for more than 20 years; for the pale, fat, and flabby infant with pot-belly and bending bones, ready victim of any chance infection, has passed unregretted into obscurity. Hitherto the children's clinics, particularly in the cities, had been crowded with victims of this malady. Grosser forms of bow-legs and knock-knees were to be seen on the operating-table, while any maternity hospital could show grim evidence of the late effects. In terms of human suffering and morbidity, the discovery of vitamin D, with its application to the treatment and prevention of rickets, must be considered the major event in the therapeutic history of this century.

About this time we had with us the problem of baby feeding. This, as a problem, has generally speaking disappeared, for with the concept of neonatal sepsis there has been a general shift in emphasis from the food to the baby. Antenatal supervision and improved midwifery have done much to mitigate this trouble, while Prof. J. C. Spence's work in the Old "Babies Hospital" at Newcastle, applying to theory the practical politics of barrier nursing, produced a big fall in the death-rate of cases of congenital pyloric stenosis which had come to operation.

So much for what has gone. What diseases, on the other hand, have appeared? Again, to my surprise, very few. I must emphasise that, speaking as a general practitioner, I take no notice of the numerous oddities which occasionally appear, to be seen perhaps once in a lifetime, or of the fairly common syndromes whose cause has been narrowed down to one or two familiar factors. Here I have in mind sciatica and that anatomical nuisance the nucleus pulposus.

In 1927 W. J. Adie lectured to our society on Some Sudden Attacks of Nervous Origin. I heard then for the first time of "spontaneous subarachnoid hæmorrhage." A year later I saw my first case.

I remember it very well, for the patient was my sister. It was the usual story—sudden severe headache, vomiting, and loss of consciousness. Some 20 hours later, a lumbar puncture was done and in a matter of minutes, as the intracranial pressure was reduced, the patient regained consciousness. I have seen quite a lot of cases since, but I have not seen one which has survived a second major attack.

NEW REMEDIES

The main changes, so far as medicine is concerned, have been in the ever-increasing number of really valuable therapeutic agents at our disposal. In my early years we had no phenobarbitone (a drug now so popular and elusive that it achieved the supreme distinction of being mentioned in the ITMA programme), no ephedrine, no insulin, no ‘Anahæmin,’ no mercurial diuretics, no Maclean's powder—*not* even ‘Lucozade.’ I find it difficult to remember what on earth we did use. Bromides, certainly, and usually, if one recalled the teaching of one's student days, in conjunction with magnesium sulphate; for this particular recipe was highly esteemed in the gynæcological department of the Royal Victoria Infirmary, where Professor Ranken-Lyle tried to teach us to recognise on sight a type of patient he called the “flat-faced neurotic”—a type known nowadays by the less picturesque and more euphemistic term “chronic anxiety state.”

---

* dential address delivered before the Newcastle upon Tyne and Northern Counties Medical Society on Oct. 6, 1949.

Purgatives, after centuries of use, were still riding high on a wave of enthusiasm; for the theory of “auto-intoxication from the large bowel,” originated by Arbuthnot Lane and stimulated by the plausible circular or blatant advertisement of the various commercial agencies, was, like King Charles II, “an unconscionable time a-dying.” Passing, too, were the days of polypharmacy; for the old blunderbuss prescription, as fanciful in its concept as a mathematical formula, was giving way slowly but inevitably before the more prosaic and utilitarian ideas of the National Health Insurance formulary. The theory of focal sepsis was even then dragging its slow length along, gathering into itself countless thousands of teeth, tonsils, gall-bladders, and colons—for the most part poor useless sacrifices.

But such things were mere fashionable trends. Scientific research was pushing on vigorously, and 1923 brought us the discovery of insulin. This was of course a major event, and needs no comment from me, except perhaps to remark in passing on the comparative rarity of diabetic coma.

1927 placed the treatment of pernicious anæmia on a rational basis. Many of us can remember three phases. In the first, this disease was recognised as invariably fatal, though with intermissions: it was treated by increasing doses of liquor arsenicalis, rest in bed, and a general hope for the best outlook. In the second phase, after Minot and Murphy's discovery but before the introduction of the liver extracts, patients had to eat half a pound of liver a day—a terrible ordeal and a stern test of endurance. (I remember one old lady who minced her daily ration, suspended it in burgundy, and drank it as a sort of cocktail.) The third phase, the parenteral injection of the liver extracts, is familiar to us all.

In this connexion, I must not forget to mention the pioneer work of Dr. C. C. Ungley in the treatment of subacute combined degeneration of the cord. I am still treating with fortnightly injections one old lady who unfortunately contracted “subacute combined” about 17 years ago—that is, towards the end of the second period. Her arms and legs were for all practical purposes useless and she was bedridden. After she had eaten liver daily for 12 months, stomach and soul rebelled, and so, at the instigation of Dr. Ungley, I began to inject her with ‘Campolon’ 10 ml. three times a week. This went on for years; but her arms and legs became gradually less numb and more useful, so that now, with the aid of crutches and at the age of 74, she manages to do quite a lot of light housework.

But important as such discoveries were, they made no appreciable difference to the work of a general practitioner; for such diseases could hardly be described as “common” in any one practice. The big change came with the discovery of the sulphonamide drugs, for in these we had a weapon with which to attack, in no uncertain fashion, a variety of diseases which had caused us considerable anxiety. I think particularly of lobar pneumonia, erysipelas, *Bacterium coli* infections, and streptococcal throats.

Pneumonia was one of the most widespread and fatal of all acute diseases, and had become—to borrow a phrase used by John Bunyan of consumption—“ c of the men of death.” As every doctor had hi ideas on its treatment, these ideas always came criticism from all friends, relations, and hang who became, for the time being, the self-app critics. Routine poulticing was the favourite re its chief virtue, to my mind, was that it gave the rel something to do and helped to keep them quiet own particular fad was what I was pleased to “masterly inactivity,” and the more seriously i patient the more fiercely did I resist any interfe Of course my results were no better nor worse anyone else's. I did learn that in general practice in the face of local tradition is never popular; b all get odd ideas at times by which we are prepai stand or fall.

I always found the case of pneumonia a wildly ex affair, for as the patient's condition grew more more desperate one became more and more c identified with the well-being and anxieties o family; for the patient was always someone's husband, or child. Though there was no specific re the presence of a doctor doing his best gave val moral support to both patient and family during the days waiting for the crisis.

My best-remembered case happened when I was much younger than I am now. A young man of 2 battling his way towards the 9th day of his illness. condition was pretty desperate and sleep his chief I got into my head the idea that his restlessness was d his becoming frightened, and that if only I could get off to sleep all would be well. And so, one afternoon, down on his bed, and told him to shut his eyes and sleep. I kept this up for about three-quarters of an Whether he became tired of my voice or sick of seeing I don't know, but he went to sleep; and when I retu some hours later he had had the crisis and was better. It of course, a colossal fluke and I recognised it as such. To I suppose it would be called psychotherapy.

TUBERCULOSIS

The early diagnosis of tubercle remains one of major problems of general practice. The standar what constitutes early diagnosis has considerably alte In the days before the general use of chest radiogra one had to depend upon the finding of abnormal phy signs in the chest or on the presence of the bacilli the sputum—a stage nowadays considered too late. theory, of course, early diagnosis is quite easy. chest is X-rayed and the problem is solved. But actual practice things can work out very differen The early signs are so slight, so varied, so indetermin that unless a doctor is tubercle-conscious an X may not be called for and precious time is wasted. all districts have access to mass-radiography un and it is quite impossible for doctors working in s areas to refer all cases that might be tubercle to t tuberculosis medical officer. One is therefore compell to resort to a sort of sifting process, and it is sm wonder that some cases slip through—no matter h fine the mesh. And how easy is it to rely upon negative film taken 6–12 months previously, only find that the patient has contracted the disease in interval.

As there is a general shortage of beds in the sanato and the patient usually has to wait some months befo admission, and as sanatorium treatment consists to great extent in rest in bed, I advise such patients to to bed until such time as they are admitted. This is, suppose, a simple precautionary measure, and it is qui easy to carry out until the patient says “Well, I've go to bed. How am I going to spend my time?” I a not prepared to admit that this is not my busine for many of these patients are youngsters who ha no idea of how to spend time and who need hel

m. it must be remembered, is a symptom, not a of bad morale. To face the diagnosis and treatment ibercle requires a deal of courage, and courage is xpendable commodity. The importance of this ple is implicit in the term " occupational therapy." nnot be applied too early.

due course the patient goes to the sanatorium and ie time returns, followed a few days later by a form from the tuberculosis office of the county il. It is a notice of his discharge, with a comment is condition and the suggested line of treatment. months of careful supervision, the results of serial y and of sputum examination, the response ie patient to whatever line of treatment has been ted—all these are summed up in one little cross ed with almost mathematical precision into one oblong. It is so simple that the least intelligent can see at a glance whether the patient has improved s not improved, whether the disease is arrested or [illegible] But from the point of view of the family r a more useless and unimaginative document be difficult to find—even amid all the rubbish has been thrown at us during recent years. I should ave supposed the turnover of patients in a sanam to be so large that the writing of adequate histories would be unduly burdensome to those in ol. Though the treatment of tubercle has been largely taken over by the specialist, the family r has still a part to play, and this part should be adequately recognised.

CORONARY DISEASE

e of my firmest impressions has been the astonishing ase in the incidence of coronary occlusion. Here d we have a problem which is essentially the of the family doctor. The unexpected onset, helming sometimes in its suddenness; the distress e patient; the threat to the family and all that it s—all combine to form a picture which can be htmare to all concerned. The treatment of the gency, the studied judgment throughout the weeks nvalescence, and the healthy adjustment of the at to his new circumstance demand a doctor's best. o easy to play too much for safety—to say " better live mouse than a dead lion," advice which can only be justified if the patient happens to have pirit of a mouse; so fatally easy to help a timorous at into the deceptive safety of a cardiac neurosis pay too little regard to the various economic s which have conditioned and must still condition atient's way of life. Only when each relevant circume has been weighed, and when the limits of cardiac nce have been defined, can a sound judgment be unced. And the only one who can pronounce it is mily doctor.

OBSTETRICS

ere is, I suppose, no branch of medicine which s a doctor more into contact with the family life s patients than obstetrics. I have been in many fortunate in that I have spent the greater part of rofessional life in a fairly small more or less static unity. Many of the children whom I delivered in arly years have now married and have children of own. I am awaiting the arrival of an infant which nable me to say that I have treated six generations amily.

ame into general practice when antenatal treatment conspicuous by its absence; when often the only e was a piece of paper thrust through the letterbox am expecting on Friday, will you please come"): the attending doctor was responsible for washing nother and bathing the baby. The local nursing iations had just been formed and midwives were only beginning to take over cases on their own. Patients sometimes found it hard to decide which was the better course to adopt. One of our local justices of the peace told with glee how he once received a note saying "Dear Sir, if you were expecting as I am expecting, would you have the nurse or the clarty doctor?" I could understand the difficulty of the writer, but I never had the courage to probe more deeply into the matter.

It did not take long for the midwives to establish themselves, and the local child-welfare clinics became more and more responsible for infant management and later for antenatal supervision. From the patient's point of view this arrangement had many good points: for wages remained low for many years, and doctors' fees, no matter how modest, were items which called for careful consideration. Always, however, there was the very great drawback that the doctor, although in name the family doctor, was not the person who had been responsible for the antenatal supervision, and was called by the midwife only in an emergency; so he tended to gain much more experience of the abnormal than the normal.

With the passage of years, the scope of routine antenatal care has widened, and in addition to blood-pressure readings, urine examinations, and pelvimetry, it now includes blood collection for grouping and for Wassermann tests. I am still wondering how I am going to tackle the case of a young and happy expectant mother who has got a positive Wassermann. For upon the wisdom and tact with which such a case is handled will depend the happiness of a young family. In any doctor's work, these two qualities, wisdom and tact, are so necessary and so hard to come by.

The control of pain during labour itself is becoming increasingly important, for we have at our disposal such important agents as 'Pethidine,' 'Trilene,' and nitrous oxide. On another plane we have the relaxation theory of Grantly Dick Read, with its emphasis on fear or anxiety producing overaction of the sympathetic and consequent muscle imbalance—a theory which seems to make obstetrics more of an art than a science. And so interested are the laity in obstetrical analgesia—and who can blame them?—that in the recent past we almost had "painless labour" thrust upon us by Act of Parliament. I find it in my heart to hope that he who was responsible for this most beneficent but ill-fated measure will be elevated to the peerage, and that he will emblazon on his coat of arms the likeness of a little child, and take as his motto the simple words "Does your mother know you're out?"

In the reduction of maternal mortality an important factor has been the introduction of the flying squad, staffed by our local consultants. This has saved the lives of many mothers, particularly by timely blood-transfusion, and many family doctors throughout our northern counties have great reason to be thankful for it. To lose a mother in a confinement is one of the greatest tragedies that can happen in general practice.

The introduction, in the early war years of special food-rationing schemes for expectant mothers has also played a not unimportant part in obstetric history. The higher standards of midwifery, the improved vigour of the newborn child, a wider knowledge of dietetics, and the advent of bacteriostatic drugs have combined to reduce the infantile death-rate, the vital statistic which reflects more than any other, the social progress of any community. But much remains to be done. A vast field for the specialised treatment of the premature infant awaits cultivation. Toxæmia of pregnancy is still with us and remains an enigma.

THE PSYCHOLOGICAL SIDE

No survey of general practice, however brief, would be complete without some reflections upon what might be called the flotsam and jetsam of medical life, the "neurotics" who haunt our consulting-rooms and test our endurance. All of them started this life heavily handicapped; but I sometimes wonder how much we, as a profession, have contributed to the end-result, either by faulty diagnosis in the early stages of an illness, by our failure to recognise the importance of emotional factors, or even perhaps by that extra cosseting which can undermine so insidiously, yet so thoroughly, the patient's confidence in himself. In this regard I welcome the more adventurous attitude of our surgeons who now encourage their patients to be up and about at a comparatively early stage in their postoperative convalescence. It may be that their reasons are the ever-present bed shortage, or a decreased liability to embolism or respiratory complications; but, speaking from the point of view of one who has to deal with such patients later on, I feel quite sure that very often early ambulation raises the patient's confidence and leads to his speedier return to work. One seldom sends a patient back to work too soon, but it is not uncommon to send him back too late.

I have not the necessary knowledge to concern myself with the various schools of psychological thought which have grown up around us. Suffice it to say that the idea of the dualism of mind and body belongs to the past, and that the phrase "the triumph of mind over matter" long ago achieved the notoriety of a cliché! We are now face to face with the idea of their essential oneness and of the physical basis of mind. It is possible that Dr. H. G. Miller's prediction that psychosomatic medicine, with "its implied dichotomy," will prove a mere phase "in the integration of psychiatry into the fabric of general medicine" has even now been justified, and that this hybrid has only turned out to be "a poor player who struts and frets his hour upon the stage and is heard no more." But whatever views one may hold on such things one cannot shut one's eyes to the fact that the so-called stress diseases are looming ever larger in our lives—the duodenal ulcer, the thyrotoxicosis, the non-renal hypertension with its vascular accidents.

Let me quote some words from Sir Heneage Ogilvie's address In Praise of Idleness [1] :

> "Body and mind seem to have been designed with a tremendous reserve of essential machinery, so that in their normal working labour and rest may alternate. In modern life they are forced to work abnormally.
>
> "These are the conditions under which a great proportion of the inhabitants of the older and more civilised communities live, and these are the conditions that are causing them to break down and are producing a group of diseases that we may call the stress diseases. In the less stoutly built it is the mind itself that gives way. In the more stable the mind remains coherent and calm and the mechanism working underneath it cracks under the strain."

Those of us working in general practice are only too familiar with the large proportion of patients coming to us complaining of a variety of symptoms which have apparently no physical basis and which must be emotionally mediated; womenfolk who after a few minutes' talk burst into tears, worried about—they know not what. The social havoc created by overcrowding, the difficulty of providing adequate meals, and the meagre family income in face of a rising cost of living are evident enough; while home life with its jealousies and frustrations, working conditions with the inevitable boredom of constant repetition, and the perpetual striving for security or self-advancement produce problems more deep-seated and therefore harder to solve. Many are insoluble. One can only do one's best and remember the old aphorism "Cure sometimes, relieve often, comfort always."

It has long been said that a good doctor is a psychologist. Whether this is true depends of cours what one means by the word "psychologist." W first this phrase was coined, it meant essentially the good doctor was a good judge of character—w is a good deal less than it implies today, for the sci of psychology, although still an infant, has gr immeasurably during the last twenty years. In student days, my only experience of such things w brief encounter with a few fairly characteristic exam of chronic delusional insanity, general paralysis of insane, and schizophrenia. The general medical w showed their usual quota of symptoms explained a as "functional." One was therefore brought up on purely mechanistic theory of disease causation, an took a long time before a mind so nurtured could rea that there was another side to the picture—that could not have a case of pneumonia, that there had be a patient suffering from pneumonia, and that ev patient required different treatment.

The passage of the years brought with it increa knowledge and experience and a fuller realisation of importance of the psyche in the ætiology and progn of disease. The acceptance of this idea was one thi but to put it into practice was another, because dire one embarked other difficulties arose. Two rules at le had to be observed. The first was that nothing sho be diagnosed as "functional" until rigid examinat had excluded all physical disease. (With the multiplic of tests at our disposal, this naturally invites the qu "What is the least number of X-ray photograp biochemical tests, and operative procedures that acceptable?" I have had occasion to wonder.) A the natural corollary was that any abnormality found was not necessarily the cause of the troub (In the end, of course, common sense and experien with a clear view of the over-all picture, are the fi arbiters.) The second rule was that, for any form psychotherapy to function properly, the patient had believe wholeheartedly in what he was told; and th one was always faced with his complete inability visualise anything other than some rather fancil disordered mechanics.

It is quite impossible for a practitioner to refer cases of mental ill health for further opinions—the are too few specialists and too few clinics; so the burd of treating the mild and early cases, and the responsibili of eliminating factors [illegible] condition [illegible] th falls inevitably upon [illegible] family doctor. Not only is he expected to give a compete opinion upon any branch of medicine or surgery wi which he may be faced; he is also expected, in a mode way, to be a psychotherapist. I am not surprised whe I hear that many of our younger graduates are slidin down towards the primrose paths of specialism.

THE FAMILY DOCTOR

As yet I have said little to justify my title. Possibl this delay is due to my reluctance to face my difficult and say what a family doctor is.

One may begin one's professional life as a gener practitioner, but one cannot begin as a family docto for this title implies a process endured, an experienc undergone. It implies, on the part of the doctor, th possession of certain qualities of mind—a persona integrity, a genuine liking for people as distinct fro things, a natural sympathy and kindliness. In thi respect, I think of some words of Sir Thomas Brown in his *Religio Medici* :

> "Let me be sick myself if sometimes the malady of my patient be not a disease unto me. I desire rather to cure his infirmities than my own necessities. Where I do him no good, methinks it is scarce honest gain, though I confes 'tis but the worthy salary of our well-intended endeavours."

---

[1] *Brit. med. J.* 1949, i, 645.

to all this I would add a fair share of that most and valuable of all commodities—wisdom. You well argue that I am painting my picture in too colours. I can only say that I prefer to regard y doctor” as an ideal at which to aim—an ideal mere scholarship takes second place to character. the many discussions revolving round the al Health Service one heard a good deal of the -patient relationship, and of the disappearance of ily doctor and family practice as we now know it. not speculate here on these topics. Medical . consulting or general, is not static and has been subject to the stresses and strains of social evolutionary forces. It has altered very considerably the last few decades, for the increasing com- of exact diagnosis and treatment has led to the th of a new species of medical man—a species e unknown to our forefathers—the specialist. There o doubt that this new growth is essential, for the alist occupies a vital place in the tracking down he more vicious or skittish diseases. It has therefore e about that this art of medicine is, more and more, ing the intimacy of the bedside, seeking more ous quarters under the cold and calculating roofs he scientific laboratories. We live in a scientific age. It is unfortunate, though perhaps inevitable, that of omniscience with which the specialist has developed by the official mind has led in some e to the denigration of the general practitioner. he is the one with the view of the whole picture is finally responsible for adapting therapy to the and ultimate well-being of the patient.

he march of 20th-century science has thrown back, in widening arcs, the frontiers of ætiology, diagnosis, treatment, enabling us to understand, in our little how it is that some things happen. It tells us ing at all of the mystery of why they happen. he years have gone on, I have become increasingly ious of the “Destiny that shapes our ends” and of truth in the very cynical old French saying: “God s, the physician takes the fee.”

E INSULIN TEST FOR VAGAL SECTION

B. N. BROOKE
M.Chir. Camb., F.R.C.S.
IN SURGERY AND ASSISTANT SURGEON TO THE
ICAL PROFESSORIAL UNIT, UNIVERSITY OF BIRMINGHAM

E value of vagal section will stand or fall on two s: (1) the possibility of ensuring that all the s of the vagus nerve have been cut: and (2) the ence-rate of ulceration after a neurectomy proved complete. A sound standardised test for vagal ity is therefore necessary, and Hollander (1946,) claims that the insulin test meets this need. This however, has not been standardised, and its results therefore be equivocal. An attempt is made here ablish standards for the test.

EXPERIMENTAL EVIDENCE

and Sivó (1925) have shown in the dog that an ion of an adequate dose of insulin causes a flow cid gastric juice. This result must come about by a local direct stimulation by insulin of the ic glands or autonomic nerve-endings, or indirectly stimulation of the hypothalamus, and thus of the s, by hypoglycæmia. For this reason we must be that insulin only acts centrally through the vagus.

and Stewart (1932) reported that an injection ulin which did not lower the blood-sugar level below per 100 ml. stimulated an acid response in a gastric . However, this was an isolated finding, and, there no evidence that the experiment was carefully controlled. nal factors may have come into play. Boldyreff and

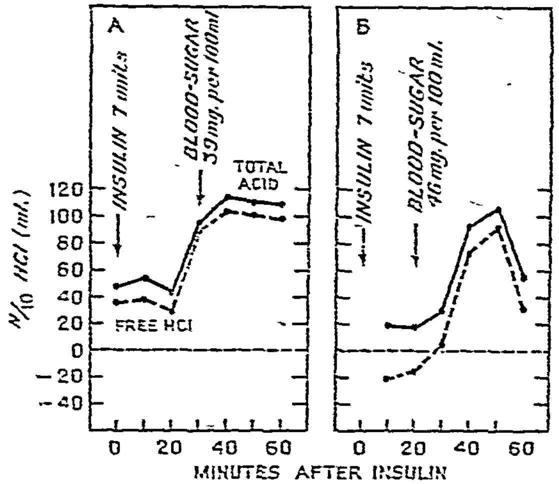

Fig. 1—Response to insulin 0·1 unit per kg. of body-weight: A, pre-operative response: B, definite positive response ten days after operation. Vertical scale represents ml. of N/10 HCl or NaCl equivalent to 100 ml. of gastric juice.

Stewart also stated that an injection of glucose given simultaneously with the insulin did not suppress the gastric secretion, but they gave no supporting data. Their evidence must therefore be discounted, since there is much good evidence that the simultaneous administration of glucose nullifies the gastric secretory effect of insulin, and that no secretion will take place unless an adequate hypoglycæmia has been produced (Okada et al. 1930, Roholm 1930).

It can therefore be assumed that the gastric secretion that follows the injection of insulin is the outcome of central stimulation of the vagus by hypoglycæmia and it is no part due to peripheral excitation of the vagal nerve-endings. The test would be more properly named the hypoglycæmia test.

BLOOD-SUGAR LEVEL

The next step is to determine what is an adequate degree of hypoglycæmia. Jemerin et al. (1943), experimenting on dogs, fashioned three different types of gastric pouches: in one the nerve supply of the pouch was preserved: in the second the vagi were partially severed: and in the third the nerve supply was completely destroyed. They found that, when the blood-sugar level was reduced to about 50 mg. per 100 ml., acid was secreted in the pouches with intact nerve supply, and in all except one out of the five partially denervated pouches, but not at all in those totally denervated. Thus, in this experiment, the test was entirely successful in demonstrating that the vagi were either completely intact or completely severed, but it was not entirely reliable in indicating partial severance. Jemerin et al. (1943) explained the failure in the one dog by suggesting that in making the partially denervated pouch all the nerve-fibres had either been inadvertently cut or had subsequently undergone degeneration. This is probably the correct explanation, but not certainly so. It is possible that the amount of acid secreted is roughly proportional to the fall in the blood-sugar, though Hollander et al. (1942) could not establish this point, and that, rather than an all-or-none effect, small areas of the stomach are controlled by each nerve-fibre, the amount secreted being a summation effect. If this is so, and if only a few vagal fibres remain, an acid response would be observed only after considerable hypoglycæmia, and at 50 mg. the blood-sugar may not be depressed sufficiently to bring about a detectable secretion. It must therefore be realised that the only certain information to be gained from the test arises from a positive or secretory response, which indicates definite vagal activity; with a negative response it cannot definitely be said that all the nerve-fibres have been cut, for the stimulation may have been insufficient to reveal activity from just a few residual fibres.

Hollander (1946, 1948) has stated that in applying the test to man it is sufficient to reduce the blood-sugar to 50 mg. per 100 ml. This is simply a direct application of the animal experiment. It may be that man's response to hypoglycæmia cannot be so closely correlated with that of the dog, and that it is necessary to reduce the blood-sugar further in man than in the dog to produce hypoglycæmic symptoms and the acid response. The early work by Roholm (1930) on this subject was done on man. He believed that the blood-sugar level should be depressed to 40–50 mg. per 100 ml. Using a dose of 12 units intravenously in 16 experiments on 9 normal persons he invariably obtained an acid secretion, and almost as invariably the blood-sugar level was lowered to below 40 mg. Can we be satisfied with a test in which the lowest level of blood-sugar reached lies between 45 and 50 mg. per 100 ml.? At the Queen Elizabeth Hospital it has been possible to study the 40–50 mg. range more closely: 182 tests were made on 177 patients before vagotomy. These tests were done under varying conditions of dosage to discover the ideal dose of insulin. The lowest blood-sugar level has varied between 32 and 96 mg. per 100 ml. In 18 cases the level fell to 46–50 mg.; in 11 of these a definite acid response was obtained; in 4 the response was uncertain; and in the remaining 3 no acid was secreted in spite of the fact that the specimens were free from bile. With a level of 46–50 mg. then, the acid response is uncertain. As opposed to this, in all of 28 cases in which the lowest blood-sugar level was 40–45 mg. a clear-cut acid secretion was obtained, even on occasion in the presence of bile. It can therefore be said that in man the blood-sugar must be brought to 45 mg. per 100 ml. or below before the test can be regarded as satisfactory. Further, these findings render sterile any argument that the acid response depends on the degree of fall from the fasting blood-sugar level, or on the rate of fall, rather than being a cons reflex at a given degree of hypoglycæmia.

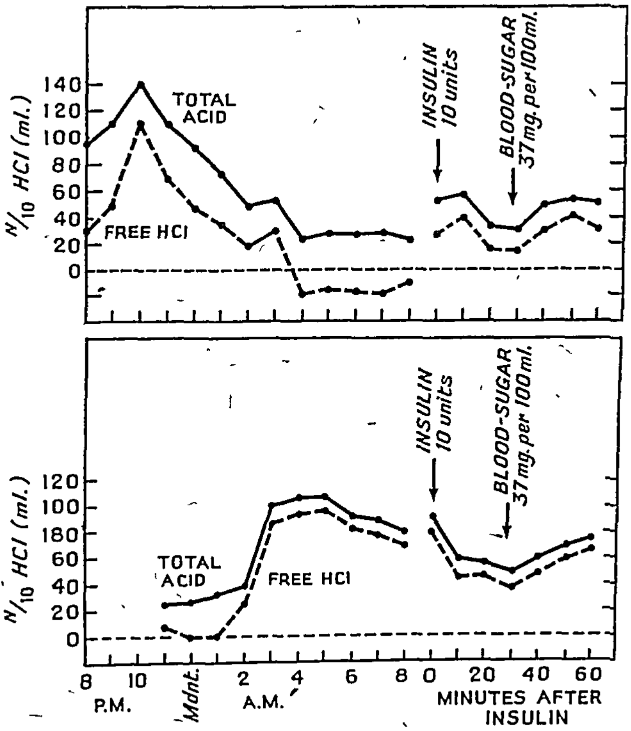

Fig. 2—Insulin tests in 2 cases six months after vagal section without gastro-enterostomy, showing acid secretion during night before test. Immediate postoperative tests in both cases had proved negative. Tests shown here reveal only a slight acid response.

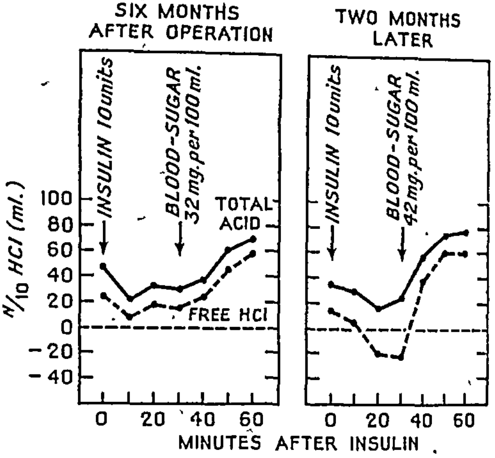

Fig. 3—Responses to insulin test, showing slow rise in acid six m after operation, and more typical rapid response in same cas months later.

METHOD

Occasion and Interpretation

For routine purposes it is only necessary to perf the test postoperatively. When the vagi are intact, quality and quantity of the acid response to hypoglycæ bear no more *relation* to the *ordinary acid* level in stomach than does the response to histamine. These "artificial" stimulants and far stronger than the nor psychical stimulus or that produced by food. A j operative test as a control for the postoperative obser tion would only be required if the response to hy glycæmia occurred at different blood-sugar levels different people. This may indeed be the case, but i certain that 45 mg. of blood-sugar per 100 ml. is low limit of the threshold if the vagi are complet intact. This level may therefore be taken as the mi mum to be attained in the postoperative test, and a preoperative test becomes superfluous.

If an acid response, closely resembling the preoperat type, is obtained during the early postoperative peri it probably indicates that a complete nerve-trunk l been overlooked (fig. 1). There are patients, howev who show no response to an adequate stimulus dur the first month after operation but secrete acid wh tested six months later. Out of 20 patients wi adequate and comparable tests carried out immediate and six months after operation, 8 responded in this wa though it is noteworthy that the acid response at s months is a modified one, in that it does not show t steep rise and the high final level characteristic of th preoperative pattern (fig. 2).

This raises the question of interpretation—can th be regarded as an acid response to hypoglycæmia an therefore as due to vagal stimulation? In answer this the following points are to be observed:

(1) In each case the increase in acid, such as it is, follo the moment when the blood-sugar reaches its minimum.

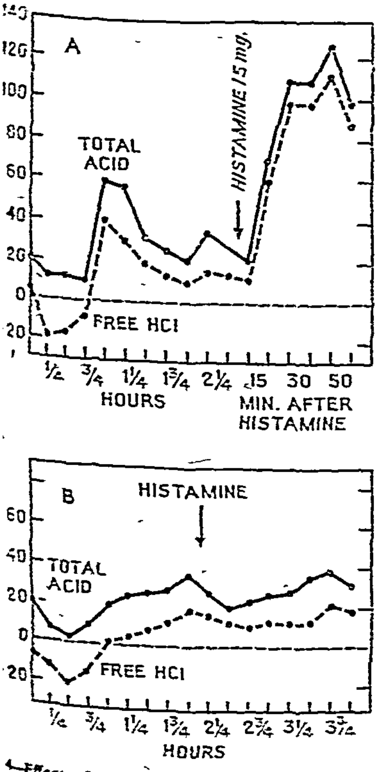
(2) Samples of resting gastric juice taken hourly throug out the night in these cases contain acid, whereas acid absent in those cases giving no acid response to the insul test (fig. 2). This nocturnal secretion of acid argues th existence of nerve-fibres, since it is difficult to conceive ho it can be produced hormonally during a twelve-hour perio of fasting.

(3) One patient who gave this modified response at th sixth postoperative month showed the typical full aci response when tested two months later (fig. 3).

As has already been remarked, there may be a summa tion of acid from separate nerve-endings in the stomach If a few fibres only are left intact rather than a whol nk, this type of modified response would be given. ther, in the recent postoperative period there is siderable gastric stasis, permitting the accumulation food and mucus which can buffer small amounts of id, thus concealing the response to insulin. In some our cases, even the response to histamine has been cured in the early postoperative period, as a result this stasis (fig. 4). Radiological studies on 69 patients months after operation have shown that gastric ne and peristalsis returned to normal in that time most cases, the only detectable abnormalities being her a slight delay in initial emptying or slow and shallow ristalsis in 14 cases, and some gastric residue after four urs in 18 cases. Sufficient recovery in gastric motility obviate the buffering effects of gross gastric stasis s therefore taken place after six months in most cases. It can therefore be seen that, though it is necessary do the test in the postoperative period only, it should done at least six months after operation to avoid reliable results.

e of Insulin

The test is done in the morning after a night's starva-n, unbroken by breakfast. The insulin is given ravenously, since in our early tests subcutaneous ministration was followed after a long interval by an certain fall in blood-sugar, making the test unmanage-le. In deciding the intravenous dose a balance has be made between avoiding gross symptoms of hypo-cæmia and depressing the blood-sugar level to 45 mg. r 100 ml. At first a dose of 0·1 unit per kg. of body-ight was tried; but, though in most cases this amount ought the blood-sugar level to about 50 mg. per 100 ml., ich was the figure we accepted at that time, it did not e a reasonably certain result. The dose was there-e fixed at 10 units, and this was made the standard all patients. This standardisation simplified the routine, and the quantity represented an *increased* dose for all but the heavy patients. It has been observed that in the immediate postoperative period the blood-sugar is reduced less easily than at any *other* time, but that, if a dose of 10 units of insulin is used for tests done either preoperatively or at six months or more after operation, the *blood-sugar will* be depressed to an adequate figure in 82% of all cases (see table). None of our patients has developed hypoglycæmic symptoms severe enough to warrant the administration of sugar.



4—Effect of gastric stasis: A, preoperative tamine response; B, lack of histamine response ing to gastric stasis and buffering effects of mach contents two weeks after vagal section thout gastro-enterostomy.

COMPARISON OF EFFECTS OF DOSAGE AND POSTOPERATIVE RESISTANCE TO INSULIN

Dose of insulin	Time of test	No. of tests with lowest blood-sugar level (mg. per 100 ml.)			Total
		Above 50 mg.	50–46 mg.	45 mg. or below	
0·1 unit per kg. of body-weight	A	15 (*31%*)	11 (*23%*)	22 (*46%*)	48
	B	10 (*56%*)	3 (*17%*)	5 (*27%*)	18
10 units	A	23 (*12%*)	13 (*6%*)	159 (*82%*)	195
	B	10 (*33%*)	3 (*10%*)	17 (*57%*)	30

A, preoperative tests and those done at six or eighteen months after operation.
B, tests done in the month after operation.

In each section the percentage of the total tests in that group is given.

This dose may therefore be regarded as almost achieving the desiderata, provided the immediate postoperative period is avoided.

In all tests the fasting blood-sugar has been estimated: further estimations have followed at ten-minute intervals up to and including the hour. In the 176 tests in which the blood-sugar level fell below 45 mg. per 100 ml. after 10 units of insulin, the time of optimal depression of the blood-sugar level was distributed thus:

Time of blood-sugar estimation after injection (min.)..	10	20	30	40	50	60
No. of tests with maximum depression at given time (out of 176 tests) ..	0	3	136	37	0	0

In the 3 tests showing the lowest blood-sugar level 20 minutes after the injection the blood-sugar level was at or below 45 mg. per 100 ml. at the 30-minute estimation, and this held good also for half the group with the lowest blood-sugar level at 40 minutes. From this it can be seen that a single blood-sugar estimation at 30 minutes after intravenous injection will provide the necessary information in 89% of all tests that reach the prescribed degree of hypoglycæmia; and two estimations—at 30 and at 40 minutes—will give 100% cover in this respect. Hollander (1948) observed that no reliance can be placed on symptoms—e.g., sweating—as indications of an adequate fall in blood-sugar. From the 334 tests done at the Queen Elizabeth Hospital it has been found that, though sweating usually begins when the blood-sugar level reaches 50–45 mg. per 100 ml., it has sometimes started at levels higher than 50 mg.: conversely, some people did not sweat when the blood-sugar level had fallen to 30–35 mg. per 100 ml. Blood-sugar estimations cannot, therefore, be eliminated.

SUMMARY

The only certain information to be obtained from the insulin test is that vagal fibres are intact when an acid secretion is obtained. The typical response shows a rapid secretion of acid.

The blood-sugar level must be reduced to 45 mg. per 100 ml. for an adequate test.

A lack of acid secretion in a postvagotomy case when the blood-sugar level is reduced to 45 mg. or less per 100 ml. cannot be regarded as certain evidence that all fibres of the nerve have been cut.

One test only is required for routine purposes, and this is best performed at least six months after operation, when difficulties arising out of gastric stasis and insulin resistance are obviated.

After 12 hours' fast the patient is given 10 units of insulin intravenously. A blood sample is taken 30 minutes after the injection to assess the blood-sugar level, and if possible another sample is obtained 40 minutes after injection.

An atypical acid response has been observed in some postoperative cases tested at six months, and its significance is discussed.

I wish to thank Dr. Garfield Thomas and his staff of the biochemical department, Queen Elizabeth Hospital, for the material they have provided in the insulin tests, and Prof. F. A. R. Stammers, C.B.E., for permission to publish this paper and for his guidance and advice.

PHYSICIAN-SUPERINTENDENT,
LENHAM SANATORIUM, KENT

IN 1948, Brownlee described the structure, properties, pharmacology, and possible clinical uses of 'Sulphetrone,' and later Brownlee and Kennedy (1948) described its suppressive effect on progressive experimental tuberculosis in guineapigs. They found sulphetrone to be bacteriostatic but, in common with other sulphones, incapable of eliminating the tubercle bacillus from animal tissues. In the same year Anderson and Strachan (1948) assessed the clinical value of sulphetrone and concluded that patients with early infiltrative lesions were most likely to benefit from treatment and that in some such cases a favourable effect had been exerted. Clay and Clay (1948), however, concluded that, at best, sulphetrone could be regarded only as an adjuvant and not in any way as a specific against tuberculosis. Madigan (1948) was more optimistic and considered that improvement was greatest in chronic lesions, and that all exudative phases of infiltrating tuberculosis were halted and reversed by sulphetrone.

The following is an account of the results * in 25 patients treated with sulphetrone in 1943. The patients, 10 male and 15 female, were selected in so far as those with predominantly infiltrating lesions were treated, since it was felt that this type of case would be the most likely to respond to chemotherapy. In a few cases an attempt to induce an artificial pneumothorax had previously been unsuccessful, and in other cases collapse measures were delayed so that no patients on sulphetrone had any other ancillary methods of treatment, apart from rest in bed.

DOSAGE

The sulphetrone was given in the same way in all the cases. After 0·5 g. eight-hourly had been given cautiously for a few days, the amount was rapidly increased until a dose of 6–8 g. daily was reached, which was usually maintained until the end of treatment. A weekly check of red cells and hæmoglobin was made, together with a weekly estimation of the blood-sulphetrone. Fluid intake was restricted to 2 or 3 pints daily in view of the rapid excretion of sulphetrone by the kidneys. Ferrous sulphate gr. 3 three times daily was given to counteract the known tendency to hypochromic hæmolytic anæmia, which develops and continues throughout the administration of sulphetrone.

TOXIC EFFECTS

Minor symptoms, such as headache, nausea, and gastro-intestinal discomfort, were occasionally observed but were never severe enough to necessitate withd of sulphetrone. Most of the patients developed a le blue discoloration of the skin and mucosæ. The cause of this has not been determined, but it seem be of no consequence and rapidly disappeared the sulphetrone was stopped.

The most notable side-effect was the hæm anæmia, which was invariably present but adequately controlled with iron.

DISCUSSION

The immediate impression was that sulphetrone responsible for some improvement, as shown by low of the erythrocyte-sedimentation rate, gain in we and occasionally conversion of the sputum. The que of the effects of enforced rest, &c. was kept u consideration, and with that in mind we felt that immediate general improvement was a little better might have been expected without sulphetrone. In case particularly, though the sputum contained tub bacilli, the organisms were cultured with difficulty, inoculation into a guineapig did not produce tu culosis. In a few cases there was radiological clea which might possibly be attributed to the sulphetron

We began to hope that sulphetrone, if not bacteric was probably bacteriostatic and might render the b avirulent so that the patient could keep the di under control or progressing at a much slower rate.

When, however, the condition of the treated pati was considered after six years, our earlier hopes not been fulfilled. Of the 25 patients, 9 are dead, 14 of the remaining 16 required some form of coll therapy. The other 2 patients are well and have tubercle bacilli in their sputum; these patients initi had hard bilateral upper zone infiltration, and one them developed a spontaneous pneumothorax dur treatment, which resolved satisfactorily. The tubercul lesion extended in at least 7 cases: in 3 during treatm and in 4 cases within three years of completing treatme In 7 cases sputum conversion was obtained, but in 2 these this happened within a week of the start of tre ment and therefore can hardly be attributed to sulphetrone. One of these developed a spread in contralateral lung and subsequently required an artific pneumothorax. Of the remaining 5 cases, in 3 sputum became positive for tubercle bacilli within f months, six months, and eighteen months; in 2 of th an artificial pneumothorax was successfully induce the third patient is dead. There remain, therefore, patients whose tuberculosis has apparently becom quiescent without the help of any factor other th sulphetrone and their own natural resistance; both of these cases had that type of tuberculosis in whi the prognosis is reasonably good and a considerab degree of healing might be expected to occur naturall

On reflection, therefore, we are not convinced th sulphetrone was responsible for any remarkable improv ment; nor, in our opinion, did it clear any case tuberculosis to a sufficient extent to prepare the patie for collapse treatment. We are particularly concern over the fact that in at least 7 patients the tuberculo spread to the contralateral lung or to a fresh region the homolateral lung; this would not happen und treatment with an effective bacteriostatic drug.

CONCLUSION

In our opinion there is no evidence that sulphetro per se has a place in the treatment of pulmonar tuberculosis.

ALLERGIC SPECIFICITY OF POLLENS

ELIZABETH BUDD
B.Sc. Lond.

JOHN FREEMAN
D.M. Oxfd

rom the Wright-Fleming Institute of Microbiology, St. Mary's Hospital, London

WHEN we started desensitisation treatment for hay-ever thirty-eight years ago we decided, first by the onjunctival reactions and later by skin tests, that the rasses were such a homogeneous group that if a man as sensitive to the pollen of any one of them he would e, more or less, sensitive to all. Experience in treatment as since proved that if he is *thoroughly* desensitised ith a vaccine made from any one of these grass pollens e will have been desensitised to all: he has had "a ure" for his hay-fever—for that year at least. Though he accent may be a little more on the "thoroughly" ow than it was then, this still holds true.

But, as more and more hay-fever patients came to e tested and treated, it was found that ome seemed to have their supposed hay-ever symptoms peculiarly late in the year, then there could be very little grass pollen n the air to explain them. One of the auses of these autumn para-hayfevers (as ve now call them) was pollen from some ompositæ—e.g., asters. For the premature ollen fevers of early spring we found he pollens of the anemophylous trees to e largely responsible.

These para-hayfever cases are of small mportance clinically because they are so ew compared with the great mass of hay-ever cases which crowd our clinics every pring for the desensitisation treatment ith grass pollen. Often, though not always, s we shall see, the para-hayfevers need heir own special pollen extracts for desensitisation; he steady search for useful pollens for the treatment f these few cases has led to some interesting work n the extent of pollen specificity of the patients.

This work is done by a combination of skin tests of the various pollens concerned, and by fractional desensitisation in a multiple sensitivity.

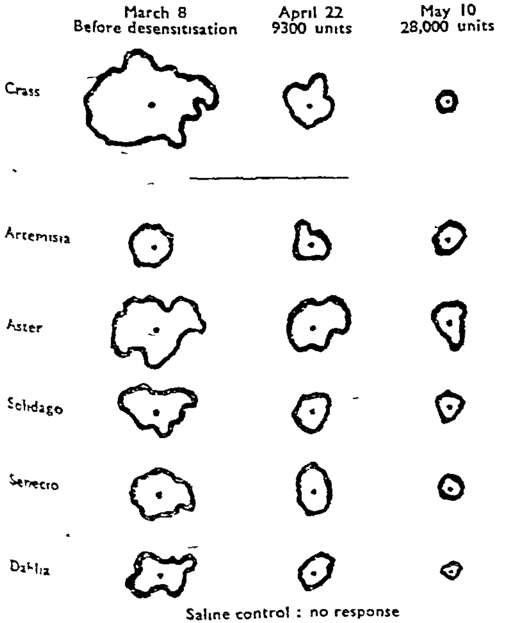

Fig. 1—An example of spread sensitisation: desensitisation with grass pollen desensitised also against other pollens.

Desensitisation is too long a story to be repeated here, and is too well known to the experts. The skin tests are by the ordinary prick technique: briefly, a drop of strong extract of the pollen in question is placed on the patient's skin; through this a prick is made with a clean needle down to the cutis vera. The drop of extract is then wiped away, and the œdema wealing is allowed to develop fully in 10–15 minutes. The outlines of these weals are recorded as shown in figs. 1 and 2; and, that these results may be given diagrammatically, the area of the weals was also calculated in square millimetres—as shown in the "sensitivity patterns" given below.

There is clearly a strong specificity separating the grass pollen from the pollens of compositæ or of anemophylous trees; 90% of our true hay-fever patients react on the skin only to grass pollen. Only 9 or 10% out of some thousands of hay-fever patients react also to one or more of the compositæ pollens which we have tried; perhaps a bare 1% of patients react to the tree pollens with which we have tried them.

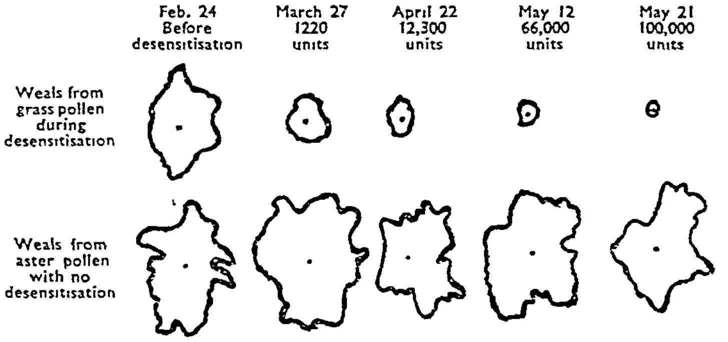

Fig. 2—An example of double sensitisation: desensitisation with grass pollen did not desensitise also against aster pollen.

The converse of this seems to be true about those few patients who come to us not for hay-fever but for para-hayfever due to pollen of trees or of compositæ. Where this is found to be authentic by skin tests, only a very few are sensitive to grass pollen also; but the numbers who come to us are too few for percentages to be cited. On treatment these para-hayfever patients give desensitisation results as good as those of the true hay-fever patients, but they need their own particular pollen extracts for successful treatment, and do not benefit from grass-pollen vaccine.

Interesting problems arise, however, with a dual or a multiple sensitivity. Most of the 10% of our hay-fever patients who are sensitive to other pollens as well as to the grass pollen have, it seems, not a double or treble sensitisation so much as a sensitivity to some protein or proteins common to all these pollens—there is a "spread" of sensitivity. Fig. 1 shows such a case: the patient needed only treatment with a hay-fever vaccine to lose her prick-test wealings with a more or less chance collection of composite pollens.

In the other group there is no such spread of sensitivity, but the patients possess two or more genuine and separate sensitivities. If such a patient is treated with grass pollen only, he often reports next year that the results were magnificent up to the middle or the end of July, but that the symptoms returned to him in the late summer and autumn. Fig. 2 shows why this should be so. Such a case needs for *complete* relief of symptoms not only grass-pollen vaccine for the hay-fever but also aster-pollen vaccine for the aster para-hayfever.

The five aster wealings in fig. 2 are about as uniform as this method of testing will allow; they would not have been more uniform if no treatment had been given. The wealings depend on other factors beside sensitisation—e.g., the patient's emotions at the time of testing—hence the slight variation.

The general diminution of the wealings to all *pollens* as shown in fig. 1 does not indicate a lessening of the patient's general sensitivity; the changes resulting from exclusive grass-pollen treatment seldom spread beyond the pollens. The spread of desensitisation follows the line of biological relationships, as has been shown by one of us, and is limited by such relationship (Freeman 1920, Freeman and Hughes 1938). Fig. 3 shows this limitation. This patient had long been sensitive to grass pollen (and some other pollens) and to white of egg; as she had successfully avoided all egg substances for fifty years, and as hay-fever was the only thing troubling her, she asked for treatment with grass pollen only. After seven years' successful treatment for hay-fever the grass-pollen weal had been permanently reduced to very small size, but the egg weal was as big as ever, or perhaps bigger. It was decided, however, to give one more year of grass-pollen treatment—but of grass-pollen treatment only. Fig. 3 shows what happened to the various wealings in consequence of this. All the pollen weals are smaller (as in fig. 1), and once again the hay-fever treatment has been a clinical success; but the egg weal is certainly not smaller.

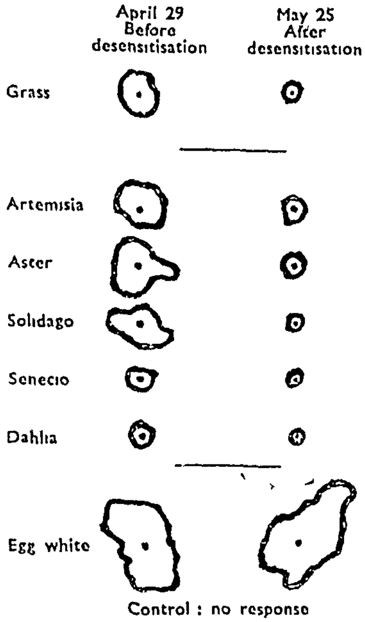

Fig. 3—An example of desensitisation limited by biological relationships: desensitisation with grass pollen desensitised also against other pollens but not against egg white.

If we examine the relative sensitivity of patients to a number of extracts of pollen of compositæ or of trees, we find the greatest diversity. Sometimes there is a strict specificity to the extract from one such pollen; other patients give a general and perhaps weak response to many or all of the pollens used for the test. Sometimes a patient is considerably affected by two or three pollens but not at all by the rest of them; there are all gr *in between, till one is driven to conclude* that there hardly be two patients alike. The arrangement of idioceptors in their blood must be very diverse. Exam of different "sensitivity patterns" of various pol sensitive patients are shown in fig. 4.

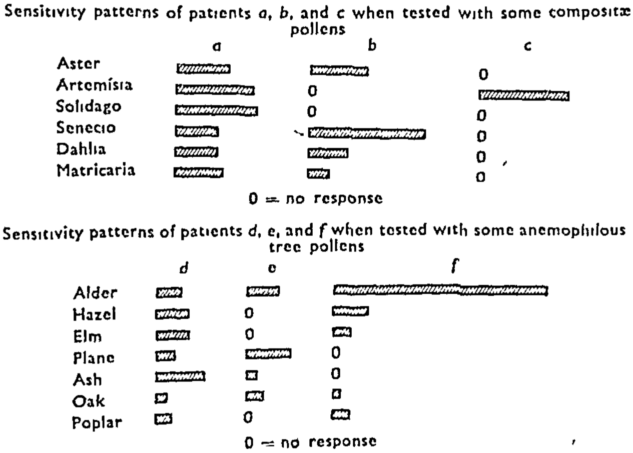

Fig. 4—Sensitivity patterns of various pollen-sensitive patients

CONCLUSION

The extract from any one pollen—e.g., of a gra must be a veritable hotchpotch of differing pro molecules. It is easy to conceive that some may found in that one particular grass's pollen only; so and it seems far more, are to be found in grass-po extracts in general, but not in pollens other than grass; some, no doubt, have a much wider distributi and this according to biological relationship. as has b said.

The next move presumably is to separate the differ protein molecules of an extract from one single gr pollen to see if different patients are sensitive equa to the same moiety.

This seems to be a matter for electrophoresis of tl extract, such as was attempted by Abramson and co-workers with ambrosia pollen in the U.S.A.

But for testing of patients one would have to further and make actual division of the fluid extr according to the molecular content. This does not se beyond the bounds of possibility even now, becau the amount of fluid necessary for a prick test is so ve minute.

ASPIRIN IN THE TREATMENT OF VASCULAR DISEASES

Paul C. Gibson
M.D., B.Sc. Lond., M.R.C.P.
PHYSICIAN, TORBAY HOSPITAL

Aspirin is an anticoagulant and it relieves pain. has previously been suggested (Gibson 1948, 1949) tl those two qualities might be effectively utilised in t treatment of *coronary thrombosis*. I have now collect evidence supporting this view, and experience sugge that for the relief of anginal pain aspirin may be super to the vasodilator drugs usually prescribed for t purpose.

It is difficult to assess the curative effects of a dr in a disease with a high natural recovery-rate, especia when the lesion is deep-seated; it is easier when t lesion is visible. If we could be satisfied that salicylat are of value in *the treatment of superficial* thrombo we might infer that they would be equally valuable thrombosis elsewhere in the vascular system. On t point my experience has been limited, but the two ca reported here, selected from others of a similar kind, encouraging, and I think justify a more *extended trial*

Of the efficacy of aspirin in anginal pain *I can spe* with greater confidence. *During the past nine mont* aspirin has been widely used in this *area* for this purpo To test the results obtained a questionary was sent o in the form illustrated below, to 22 doctors, of who 20 replied. Of these, 5 had not used it. Of the who had used it, 8 considered it was of *undoubted va in* relieving and preventing anginal *pain*; the r thought it was of some value; *none thought it usele* It must be noted that no details were asked for abo the type of case or the method of prescription, and realise that, to be of statistical value, *such* data must carefully defined. I merely *claim that* a prima fac case has been established for a more extensive trial *aspirin in coronary* disease. In making this suggestio ave in mind that salicylates have maintained their ation in the treatment of rheumatic carditis for e than fifty years with little scientific justification. haps a common factor in the pathogenesis of these conditions is increased coagulability of the blood. this connexion it is interesting to note that Magary 9) seems to have shown that the organisation of ace deposits of fibrin contributes to the progressive elopment of mitral stenosis, and Glazebrook and gley (1949), comparing the effects of heparin and ylate in the treatment of acute rheumatism, d that the results obtained with heparin differed little from those obtained with salicylate, which firmed the good clinical results claimed by Wasser Zander (1946) with heparin and dicoumarol in matic fever.

THE QUESTIONARY

have used aspirin in..........cases of anginal pain and der that it is of no use,* of some use,* of undoubted value* lieving* and preventing* this pain.

CASE-RECORDS

se 1 (Dr. M. Wigram: *Chronic Thrombophlebitis of Legs*). married woman, aged 47, had had goitre in adolescence; matic fever at the age of 20; "white leg" (left), for which ad spent 6 months in bed, in 1927; phlebitis in her right fter injection for varicose veins in 1938. In April, 1948, itis had recurred in both legs and persisted. In October apparently not related to exertion, had developed in eck, arm, and pectoral region on the left side. Her r said she had hardly been able to leave her room for months, because of the condition of her legs.

Dec. 8, 1948, the patient was seen at Torbay Hospital, she could not walk without pain in the legs. Both lue and œdematous. Right and left internal saphenous swollen and tender. No abnormal physical signs in , lungs, or abdomen. Pulse regular, rate 100 per ; blood-pressure 160/110 mm. Hg. No obvious goitre. rocardiogram showed simple tachycardia. Urine normal. er over left cervical plexus. All deep reflexes in upper lower limbs were brisk. No wasting or sensory loss in arm or hand. Radiography showed enlargement of erse processes of C7. The pain in the arm was conus and related to movement rather than to exertion.

eatment.—A mixture containing aspirin gr. 20 was given times daily. This made the patient deaf, so the dose reduced to gr. 10 t.d.s. She tolerated this and continued his dosage for four months, since when she has taken daily.

ogress.—Her doctor reported that after two weeks on n the patient could walk without pain. He reported on Oct. 15, 1949: "The legs have been wonderful since started aspirin, and the veins have to a large degree peared. The pain in the chest is better and does not go the arms. Her main complaint now is cramp on walking; ould not walk before."

Case 2 (Dr. W. S. Baxter: *Temporal Arteritis*).—A man, aged 67, had five months' history of vertical headache followed shortly by pains in the arms and legs, ascribed to rheumatism; and three months' history of painful swelling of the right temporal artery. He said he had lost 6 lb. in five months.

On May 25, 1949, he was seen at Torbay Hospital, when his weight was 8 st. in clothes. His temperature was 97·4°F. He was edentulous and wore dentures. Pulse regular, rate 76 per min., blood-pressure 120/80 mm. Hg. No abnormal physical signs in heart, lungs, or abdomen. Urine normal. Electrocardiogram normal. Erythrocyte-sedimentation rate (E.S.R.) 38 mm. in 1 hour. Fundi normal. The right temporal artery was red, swollen, and nodular.

Treatment and Progress.—Aspirin gr. 10 four times daily was ordered. After the patient had taken aspirin for two weeks the pain in the temporal artery stopped, but the vertical headache and limb pains persisted and the E.S.R. was now 55 mm. in 1 hour. The right temporal artery was no longer red or tender. On July 20 there was no pain or tenderness in the temporal artery, though it felt rather hard. The headache persisted. Hypochromic anæmia was present. Aspirin was stopped, and iron by mouth and liver injections were given. On Sept. 14 the temporal artery was normal, and the anæmia was improving.

Case 3 (Dr. M. Lees: *Persistent Anginal Pain on Exertion and at Rest*).—A man, aged 60, had had coronary thrombosis in the Army in 1942, for which he had been in hospital four months. Since then he had had asthenia, loss of weight, angina of effort, and frequent long (up to 2 hours) attacks of angina at rest. Trinitrin relieved the effort pain but not the long attacks at rest. In February and June, 1949, cerebral attacks had come on, associated with headache, giddiness, and hemianopia. During the past two months the effort pain had been more disabling and long attacks of severe retrosternal pain, radiating into both arms, had occurred daily.

On Sept. 27 the patient weighed 10 st. $^1/_2$ lb. in his clothes. Pulse regular, rate 50 per min.; blood-pressure 180/115 mm. Hg. Apex-beat forcible and felt beyond its usual site. Soft systolic murmur heard over aortic area. No signs of aneurysm or of pulmonary congestion. Nothing grossly abnormal in the fundi. Left quadrantic hemianopia. Knee-jerks and ankle-jerks brisk. Pupils equal and reacted to light. Urine normal. Electrocardiogram showed inversion of T1 and T4.

Treatment and Progress.—Aspirin gr. 10 t.d.s. had been started two weeks previously. Since then the patient had had no pain at rest and the effort pain had been much less easily induced. On Oct. 10 his doctor reported that his condition remained most satisfactory. The patient has had no more attacks of pain at rest, but he still gets pain if he walks too far or too fast.

Case 4 (Dr. W. S. Baxter: *Severe Angina of Effort with Acute Lung Congestion*).—A man, aged 73, had had his enlarged prostate treated by diathermy eleven years ago, since when he had had pyuria. Angina of effort began in March, 1948, and persisted with increasing intensity and frequency. In April, 1948, he began to have attacks of pain on exertion associated with acute dyspnœa and bloody expectoration; these were relieved by trinitrin. When seen at his home on April 22, 1948, the patient was ambulant and had no pain except on exertion. Pulse regular, rate 72 per min.; blood-pressure 160/90 mm. Hg. Apex-beat and heart sounds obscured by thick chest. No murmurs heard. No signs of congestion in lungs. Liver not palpable. No œdema. Electrocardiogram normal in four standard leads.

On admission to Torbay Hospital on June 5, 1948, the patient was having daily attacks on the least exertion, with retrosternal pain radiating to the arms, intense dyspnœa, cyanosis, and abundant frothy bloodstained sputum. The attacks were relieved by trinitrin. No moist sounds were heard in the lungs between the attacks. The cardiovascular signs were as before, and another electrocardiogram was normal. Pulse-rate 60–80 per min., temperature normal. Wassermann negative. Radiogram of chest showed no aneurysm or neoplasm. Urine purulent, output 50–60 oz. daily.

Treatment and Progress.—Nicotinic acid 200 mg. t.d.s. was ineffective. On June 29 nicotinic acid was stopped, and aspirin gr. 20 four times daily was started. There were no more attacks after the first dose. The patient gradually resumed normal activities. After six weeks in hospital he was discharged with no serious cardiac disability. He had no further anginal attacks during the rest of his life. No other treatment than that recorded was given except phenobarbitone at night, which he had taken since March. He developed retention of urine and was readmitted for this in October, 1948. Suprapubic cystotomy was done, which he tolerated well. It was found that he had a malignant prostate, and he died from this in April, 1949.

METHOD OF ADMINISTRATION

The dosage adopted is that used for rheumatic carditis. With such massive dosage the possibility of toxic effects must be borne in mind. Graham and Parker (1948), using sodium salicylate for rheumatic and non-rheumatic diseases, found that minor symptoms, such as tinnitus, deafness, nausea, and vomiting, were common but disappeared if the treatment was continued. This is in keeping with our experience.

It seems undesirable to flood with sodium the tissues of patients with potential congestive failure, and it does not seem right to give large doses of calcium for thrombosis, so aspirin is the preparation of choice. But this is a local irritant. Douthwaite and Lintott (1938) found by gastroscopy that aspirin caused local inflammation of the gastric mucosa. They thought the inflammation was usually confined to the lesser curvature, so their method of administration was designed to ensure good contact of the aspirin with this area. They gave gr. 15 of crushed aspirin, washed down with 1 oz. of water, immediately after aspiration of the stomach contents. To attain their purpose they aimed at maximal concentration, so to avoid their results we should aim at maximal dispersion. To this end I give the aspirin suspended with tragacanth immediately after a meal. I have rarely had complaints and so far have never had to abandon treatment because of discomfort. Because salicylates increase the excretion of vitamin C ascorbic acid is added to each dose. Two standard mixtures are used, full and half strength, as follows :

Aspirin gr. 10 or 20.
Ascorbic acid 50 mg.
Pulv. tragacanth q.s.
Aq. menth. pip. ad $^1/_2$ oz.

For coronary thrombosis I give the gr. 20 mixture four-hourly after meals and during the night after a cupful of warm milk. This is continued for ten days or until the E.S.R. and leucocyte-count are normal. The half-strength mixture is then substituted and given four times daily for as long as seems desirable. For anginal pain without evidence of thrombosis I usually prescribe the half-strength mixture, to be taken three or four times daily for as long as is required.

SUMMARY

The apparent effect of aspirin therapy on superficial thrombosis suggests that it is an effective anticoagulant.

It can also be relied on to relieve and prevent even severe anginal pain.

It is therefore suggested that aspirin should be used in the treatment of coronary thrombosis and angina pectoris in the same way that it is used for rheumatic carditis.

To avoid its gastric irritant effects the aspirin should be suspended in a mixture.

I wish to thank the doctors, too many to mention individually, who have coöperated in this work.

CERVICODORSAL OSTEOMYELITIS W
EXTRADURAL ABSCESS

D. B. ALLBROOK
M.B. Lond.
LATE RESIDENT MEDICAL OFFICER, MILDMAY MISSION HOS
LONDON

EXTRADURAL abscess of the spine is rare, but of considerable general interest in relation to diagnos treatment. The onset is fairly acute, with fever, l cytosis, local tenderness, and pain radiating alon distribution of the nerve-roots. This is followe compression of the spinal cord and partial or com subarachnoid block, often associated with throm of spinal blood-vessels caused by staphylococcal exo

Clinically, the appearance is that of a rapidly dev ing paraplegia. But the diagnosis may be diff since the paralysis may overshadow everything and the underlying lesion suggested by the early sig infection passes unobserved. Wilensky (1934) em sised this, pointing out that "the phenomenon of inflammation may be lost in a maze of neurol evidence."

Because the dorsal extradural space is only pot at this level, cervical and upper dorsal extradural ab is the least common site, and few cases have been repo Of 14 cases of spinal osteomyelitis with extradural ab reported by Browder and Meyers (1937, 1941) 3 in the cervical region. Kaplan and Read (1947) rep *1 case with extradural infection* without parapl cured with penicillin alone. Cattan and Corcos (recorded a case with quadriplegia which recovered treatment with sulphonamides, Delbet vaccine, penic and immobilisation, without laminectomy.

Finch (1947) reported a case of cervical osteomy of C3 and C4 in a baby aged 11 days. The in had upper-limb paralysis but no paraplegia. Treat with sulphadimidine ('Sulphamezathine'), penicillin, aspiration of the pus was successful. The abscess poi to the skin surface because of the softness of the tis Pressure on the cord never developed. Paralysis thought to be due to the pressure of granulations peripheral nerves. In an adult, on the other h paraplegia may supervene, since the pus is confined the thick ligaments and fascial layers, making lami tomy and drainage necessary to relieve pressure the cord.

The following case illustrates some of the spe problems raised by this condition.

CASE-RECORD

A soldier, aged 20, previously fit, was admitted to Mildmay Mission Hospital on Nov. 1, 1948, with a f night's history of diarrhœa, sore throat, and a crop pimples over his back. Eight days before admission was lifting a weight when he felt a sudden pain ac "the top of his shoulders." During the following week felt "off colour." The pain in his shoulders came and w and he developed a painful cough. Five days after the "b strain" he noticed clumsiness and numbness when using ring and little fingers of his left hand. On the seventh when he tried to get out of bed his legs collapsed bene him, and he could not pass his water next day.

The following day he could neither use his legs nor urin The left arm felt numb, the right hand felt weak, and it h him to turn his head from side to side.

On examination the patient was coöperative and alert but paraplegia and urinary retention. There was still some po in both legs, and the chest and abdominal muscles were paralysed. The reflexes were all brisk. The plantar respon were equivocal, but bilateral ankle clonus was pres There was sensory loss up to the knees. The optic di looked normal. Turning of the head was painful, and th was tenderness over the spines of the cervical verteb Whi Temperature, pulse-rate, and respirations were normal.

count : 16,000 per c.mm. (polymorphs 72%, lymphocytes %, monocytes 1%, eosinophils 1%). Lumbar puncture aled clear fluid, the pressure of which did not rise when ssure was exerted over the jugular veins. The cerebrospinal id (C.S.F.) contained 1 cell per c.mm., protein 450 mg., and rides 700 mg. per 100 ml. ; globulin was present. The ssermann reaction and Kahn test were negative in the S.F. Radiologically, there appeared to be a small destructive ion of the right transverse processes of C6 and C7 tebræ.

Progress.—Next day there was complete paralysis of all the abdominal, and lower intercostal muscles. The arms were ak, but the face was unaffected. The ankle and knee ks were absent, plantar reflexes were feebly flexor, and m-jerks all diminished. There was loss of all forms of sation up to L1–2. Local signs in the neck were unchanged. at night the patient's temperature rose to 103°F. A blood-nt showed red cells 4,200,000 per c.mm., Hb 84%, white ls 18,200 per c.mm. (polymorphs 74%, lymphocytes 21%, nocytes 3%, eosinophils 2%). Lumbar puncture revealed spinal block : the C.S.F. was yellow and opalescent, and tained 10 white cells and 150 red cells per c.mm. ; protein 0 mg. per 100 ml. ; globulin was present. On culture the S.F. was sterile. A course of penicillin, 50,000 units ramuscularly, four-hourly, was started.

On Nov. 3 ascending paralysis had involved all the inter-stal muscles and all the arm muscles except the biceps and pinator longus muscles on both sides. Dullness and fine râles re noted at both lung bases. The patient was rational t very sleepy. Blood-culture was sterile after three days' ubation. Dr. N. G. Hulbert saw the patient and diagnosed rvical extradural abscess ; he advised laminectomy.

Operation (Mr. J. T. Fathi).—On Nov. 4, under thiopentone, s, oxygen, and trichlorethylene anæsthesia an incision r cervical laminectomy was made from vertebral spines to D3. As soon as the spines were exposed, pus pointed the level of D2. When the paraspinous muscles were racted a large abscess, extending from vertebral level to D2 was opened ; this distended the extradural space, nting through the intervertebral ligaments from C7 to D1. minectomy of D1 and D2 was done. The abscess cavity opened in all directions, and several ounces of creamy was evacuated from the extradural space. Pressure on cord was relieved, and extradural fat was seen pulsating. cavity was dusted liberally with penicillin and sulpha-zole powder and closed in layers, with serum-proof silk, and all drainage tube was inserted. Two pints of blood was en by slow intravenous drip. Culture of the pus grew gulase-positive *Staph. aureus.*

Postoperatively the patient never regained consciousness, ugh he moved his arms and legs and the intercostal scles were again working. Lumbar puncture showed that spinal block had been relieved. The C.S.F. on Nov. 5 under a pressure of 260 mm. of C.S.F. and contained white cells per c.mm., protein 90 mg. and chlorides 700 mg. r 100 ml. ; globulin was present.

The patient's general condition rapidly deteriorated, the nical picture resembling an overwhelming pyæmia and ticæmia, with temperature rising to 106°F and ecchymoses earing in the skin.

In view of this the dosage of penicillin was raised to 250,000 ts four-hourly, and four-hourly intravenous injections of adiazine 1 g. were started, but the patient died on . 5.

COMMENTS

The onset of symptoms in this case was insidious, tending over a whole week. Paraplegia, spinal block, al tenderness, and signs of infection were the out-anding features. The differential diagnosis therefore luded poliomyelitis, ascending myelitis, tuberculous ries of the spine, and a space-occupying lesion in e cord.

The staphylococcus isolated was sensitive to penicillin n vitro, but neither the abscess nor the circulating pus as sterilised in vivo. Blood-culture was sterile before e operation, but it is possible that the lesion was etastatic from the crop of skin boils a week previously.

Because of the well-developed tissues in an adult man eration was a necessity, since the pus could not point the skin surface as it would in an infant (Finch 1947). The operation relieved the spinal block, but the massive dissemination of organisms in the blood-stream that it caused could not be controlled by chemotherapy, and so death resulted from pyæmia and toxæmia.

I wish to thank Mr. J. T. Fathi and Dr. N. G. Hulbert for their help and encouragement, and Dr. A. J. Watson, medical superintendent of the Mildmay Mission Hospital, for permission to publish this case.

SPONDYLITIS ANKYLOPOIETICA WITH SEVERE ANÆMIA PRESENTING AS ACUTE ABDOMINAL DISEASE

ELIZABETH DE C. FALLE
M.B. Lond., M.R.C.P., D.C.H.
MEDICAL REGISTRAR

E. MONICA BENNETT
M.B. Camb.
HOUSE-PHYSICIAN

WEST LONDON HOSPITAL, HAMMERSMITH

THE following case of spondylitis ankylopoietica was unusual in its mode of presentation and also in the association with a severe hypochromic anæmia.

A man, aged 34, whose job as a lathe-maker involved much stooping and weight-lifting, was first seen in the outpatient department of the West London Hospital in August, 1948, with a fortnight's history of sharp attacks of abdominal pain ; this pain had been of gradual onset, affected chiefly the right hypogastrium and loin, and doubled him up.

On examination the patient was extremely thin, depressed, and very pale, with generalised abdominal guarding and great tenderness in the right renal angle. Though apyrexial, he was admitted to a surgical ward with the provisional diagnosis of a right perinephric abscess associated with severe anæmia. It was in the X-ray film taken before intravenous pyelography that bilateral destruction of the sacro-iliac joints was noticed, whereas pyelography, examination of the urine, and a barium meal all showed no abnormality. Though the spine appeared radiologically normal, the correct diagnosis of spondylitis ankylopoietica was confirmed clinically by finding painful limitation of all spinal movements and a chest expansion of only $^3/_4$ inch.

Further questioning of the patient revealed that nine years previously he had been treated for right sciatica (aching pain from buttock to popliteal fossa causing his leg to give way). Intermittently this had troubled him since, especially in the cold weather and on walking. For the past fifteen months he had been treated for "nervous debility"—i.e., anorexia, lassitude, weakness, depression, right epigastric pain two hours after food, and a loss of two stone in weight. He had been unable to take more than one balanced meal daily. At work, which he had only been able to manage spasmodically in spite of a light job, his pallor had been commented on.

Treatment and Progress.—The spondylitis was treated by rest in a plaster bed for eight weeks, breathing exercises, and a course of deep X-ray therapy, localised in turn to each part of the spine. The man's symptoms improved steadily till spinal movements no longer caused severe pain. His chest expansion increased to $1^1/_4$ inches, but a dorsal kyphosis and rigidity of the lumbar spine persisted.

The patient had a severe microcytic hypochromic anæmia on admission—Hb 36%, red cells 3,300,000 per c.mm., colour-index 0·5—and an erythrocyte-sedimentation rate (E.S.R.) of 37 mm. in the 1st hour (Westergren). Transfusion of 2 pints of blood raised the Hb to 56% and red cells to 4,460,000 per c.mm. Thereafter the patient responded remarkably well to ferrous sulphate gr. 3 t.d.s., his Hb increasing to 78%, and red cells to 4,560,000 per c.mm., in the first week, and later more gradually during his course of deep X-ray therapy, to 96% and 4,920,000 per c.mm. by the end of the sixth week. His E.S.R. rose to 50 mm. in the 1st hour at the end of the first month, but had fallen to 9 mm. in the 1st hour by the end of the second month, and his depression vanished.

more attacks after the first dose. The patient gradually resumed normal activities. After six weeks in hospital he was discharged with no serious cardiac disability. He had no further anginal attacks during the rest of his life. No other treatment than that recorded was given except phenobarbitone at night, which he had taken since March. He developed retention of urine and was readmitted for this in October, 1948. Suprapubic cystotomy was done, which he tolerated well. It was found that he had a malignant prostate, and he died from this in April, 1949.

METHOD OF ADMINISTRATION

The dosage adopted is that used for rheumatic carditis. With such massive dosage the possibility of toxic effects must be borne in mind. Graham and Parker (1948), using sodium salicylate for rheumatic and non-rheumatic diseases, found that minor symptoms, such as tinnitus, deafness, nausea, and vomiting, were common but disappeared if the treatment was continued. This is in keeping with our experience.

It seems undesirable to flood with sodium the tissues of patients with potential congestive failure, and it does not seem right to give large doses of calcium for thrombosis, so aspirin is the preparation of choice. But this is a local irritant. Douthwaite and Lintott (1938) found by gastroscopy that aspirin caused local inflammation of the gastric mucosa. They thought the inflammation was usually confined to the lesser curvature, so their method of administration was designed to ensure good contact of the aspirin with this area. They gave gr. 15 of crushed aspirin, washed down with 1 oz. of water, immediately after aspiration of the stomach contents. To attain their purpose they aimed at maximal concentration, so to avoid their results we should aim at maximal dispersion. To this end I give the aspirin suspended with tragacanth immediately after a meal. I have rarely had complaints and so far have never had to abandon treatment because of discomfort. Because salicylates increase the excretion of vitamin C ascorbic acid is added to each dose. Two standard mixtures are used, full and half strength, as follows :

Aspirin gr. 10 or 20.
Ascorbic acid 50 mg.
Pulv. tragacanth q.s.
Aq. menth. pip. ad $^1/_2$ oz.

For coronary thrombosis I give the gr. 20 mixture four-hourly after meals and during the night after a cupful of warm milk. This is continued for ten days or until the E.S.R. and leucocyte-count are normal. The half-strength mixture is then substituted and given four times daily for as long as seems desirable. For anginal pain without evidence of thrombosis I usually prescribe the half-strength mixture, to be taken three or four times daily for as long as is required.

SUMMARY

The apparent effect of aspirin therapy on superficial thrombosis suggests that it is an effective anticoagulant.

It can also be relied on to relieve and prevent even severe anginal pain.

It is therefore suggested that aspirin should be used in the treatment of coronary thrombosis and angina pectoris in the same way that it is used for rheumatic carditis.

To avoid its gastric irritant effects the aspirin should be suspended in a mixture.

I wish to thank the doctors, too many to mention individually, who have coöperated in this work.

CERVICODORSAL OSTEOMYELITIS V EXTRADURAL ABSCESS

D. B. ALLBROOK
M.B. Lond.
LATE RESIDENT MEDICAL OFFICER, MILDMAY MISSION HO
LONDON

EXTRADURAL abscess of the spine is rare, bu of considerable general interest in relation to diagno treatment. The onset is fairly acute, with fever, cytosis, local tenderness, and pain radiating alo distribution of the nerve-roots. This is follow compression of the spinal cord and partial or co subarachnoid block, often associated with thro of spinal blood-vessels caused by staphylococcal exo

Clinically, the appearance is that of a rapidly de ing paraplegia. But the diagnosis may be di since the paralysis may overshadow everythin and the underlying lesion suggested by the early si infection passes unobserved. Wilensky (1934) e sised this, pointing out that " the phenomenon o inflammation may be lost in a maze of neurol evidence."

Because the dorsal extradural space is only pot at this level, cervical and upper dorsal extradural a is the least common site, and few cases have been rep Of 14 cases of spinal osteomyelitis with extradural a reported by Browder and Meyers (1937, 1941) 3 in the cervical region. Kaplan and Read (1947) rep 1 case with extradural infection without parap cured with penicillin alone. Cattan and Corcos (recorded a case with quadriplegia which recovered treatment with sulphonamides, Delbet vaccine, peni and immobilisation, without laminectomy.

Finch (1947) reported a case of cervical osteom of C3 and C4 in a baby aged 11 days. The i had upper-limb paralysis but no paraplegia. Treat with sulphadimidine (' Sulphamezathine '), penicillin aspiration of the pus was successful. The abscess po to the skin surface because of the softness of the ti Pressure on the cord never developed. Paralysis thought to be due to the pressure of granulation peripheral nerves. In an adult, on the other h paraplegia may supervene, since the pus is confine the thick ligaments and fascial layers, making lam tomy and drainage necessary to relieve pressur the cord.

The following case illustrates some of the sp problems raised by this condition.

CASE-RECORD

A soldier, aged 20, previously fit, was admitted to Mildmay Mission Hospital on Nov. 1, 1948, with a night's history of diarrhœa, sore throat, and a cro pimples over his back. Eight days before admissio was lifting a weight when he felt a sudden pain a " the top of his shoulders." During the following wee felt " off colour." The pain in his shoulders came and and he developed a painful cough. Five days after the " strain " he noticed clumsiness and numbness when using ring and little fingers of his left hand. On the seventh when he tried to get out of bed his legs collapsed ben him, and he could not pass his water next day.

The following day he could neither use his legs nor uri The left arm felt numb, the right hand felt weak, and it him to turn his head from side to side.

On examination the patient was coöperative and alert but paraplegia and urinary retention. There was still some p in both legs, and the chest and abdominal muscles were paralysed. The reflexes were all brisk. The plantar respo were equivocal, but bilateral ankle clonus was pre There was sensory loss up to the knees. The optic looked normal. Turning of the head was painful, and t was tenderness over the spines of the cervical verte Temperature, pulse-rate, and respirations were normal. W

SUMMARY OF REPORTED CASES OF INFANTILE CORTICAL HYPEROSTOSES

uthor	Age at onset (mos.)	Presenting symptoms	Bones affected	Soft-tissue swelling	Fever	Leucocytosis	Anemia	Other features	Duration
ley and rerman 1945)	1¾	Fever, irritability, tenderness lt. leg	Mandible, clavicles, ribs, rt. humerus, femora, tibiæ	Both legs	+	+	—*	Pleural exudate, spleen palpable	Inactive at 4 mos., normal at 6 yr.
	2	Swelling face, fever	Mandible, ribs, humeri, radii, ulnæ, femora, tibia	Face, forearms	+	—	+	Pleural exudate	Radiological changes after 10 mos., normal at 5 yr.
	2½	Swelling face, irritability	Mandible, clavicles, lt. scapula, ribs, lt. humerus, femora, tibiæ	Face, scapular region	—	+	—	Pleural thickening, seborrhoic dermatitis	Practically normal in 10 mos.
	½	Swelling scapular region, restricted shoulder movement	Mandible, clavicle, rt. scapula, humeri, femora	Face, scapular region	—	—	—	Elevation rt. diaphragm, dysphagia	Radiological changes remain at 4 yr.
affey 1946)	4	Swelling cheeks, irritability	Mandible, clavicles, rt. radius, ulnæ	Face, neck	—	+	+	..	Asymptomatic after 3 weeks
	18	Swelling lt. leg and foot, irritability, anorexia	Clavicles, ribs, rt. ulna, rt. femur, lt. tibia, rt. fibula, metatarsals	Lt. leg and foot	—	—	—*	Night sweating	Asymptomatic after 9 mos., but radiological changes remain
	1¾	Swelling cheek	Mandible	Face	—	+	—	..	Asymptomatic after 9 mos., but radiological changes remain
	4	Swelling face, fever	Radius, femora, tibiæ, fibulæ (other bones not radiographed	Face, rt. leg	—	..	..	..	Still febrile after 4 mos.; no further follow-up
	20	Fever, aching joints, refusal to walk	Lt. clavicle, lt. radius, ulnæ, rt. femur, tibiæ, metatarsals	..	—	+	—	Tenderness long bones	Asymptomatic after 2 weeks
	3	Swelling face	Parietal bones, mandible, rt. clavicle,	Face, scalp, sternoclavicular region	+	+	+	..	Still symptoms after 8 weeks
	3½	Irritability, tenderness face	Mandible, ribs	Face	+	+	—*	..	..
	3	Fever, irritability, swelling face	Mandible, clavicles, ulnæ, femora, tibiæ	Face, forearms, legs	+	—	+*	Shadow superior mediastinum	Normal after 2 yr.
	1½	Irritability, swelling, face, gastro-enteritis	Mandibles, clavicles, lt. humerus, radii, ulnæ, femora	Face, arms, lt. leg	—	+	..*	..	Slight residual changes after 6 mos.
th et al. (1946)	2	Upper respiratory infection with fever and irritability	Mandible, ribs	Face, lt. scapular region	+	—	+*	..	..
	3	Swelling face and pain	Nil	Face	+	—	+	"Suggestion of pleurisy" in radiograph	..
	21	Intermittent swelling arms, feet, scalp	Clavicles, ribs, ulna, rt. femur	Scalp, neck, lt. forearm, legs, feet	..	+	+	..	Much improved after 9 mos.
	30	Intermittent fever, irritability	Nasal bones, radius, ulna	..	..	—	—	Malnourished	..
(1939)	4	Fretfulness, swelling lt. forearm, poor weight-gain	Lt. radius, ulnæ	Lt. forearm	—	—	—	"Suggestion of vitamin-C deficiency from urine tests	Subsiding after 2 mos.
on et al. (1947)	2	Swelling scapular area	Mandible, rt. clavicle, rt. scapula	Scapular region	..	+	+	..	Cleared in 7 mos.
hipple (1947)	3	Irritability, tender swelling face	Skull, mandible, clavicles, ribs	Face, occiput	+	+	+	..	..
(1947)	4	Swelling cheek and forearm	Mandible, rt. ulna	Face, neck clavicular region	+	+	+	..	Almost cleared in 6 mos.
(1948)	3½	Swelling face	Mandible, lt. clavicle, ribs, lt. ulna	Face, lt. arm	+	—	+*	Primary tuberculous lesion in chest, spleen palpable	Cleared in 6 mos.
uman (1948)	4	Swelling face, fever	Mandible, clavicles, ribs	Face, rt. forearm, clavicular region	+	+	—	..	Almost cleared in 6 mos.
son and k (1948)	2	Swelling and tenderness rt. forearm	Mandible, clavicles, scapula, ribs, rt. radius, rt. ulna	Face, rt. forearm, clavicular region	+	+	..	..	Still present after 6 mos.
n Zeben (1948)	1½	Swelling lt. leg	Clavicles, rt. humerus, lt. tibia	Lt. leg	—	..	..	Parents have had syphilis	Disorder disappeared after 13 mos.
	2	Swollen, painful legs	Mandible, humeri, radii, tibiæ	Mandible, legs	..	—	+*	Brother of previous case	Died with mastoiditis 3 weeks after admission
	3	Swollen, painful legs	Humerus, radius, ulna, femur, tibiæ	Legs	—	+	—	Cousin of 2 previous cases	Improving radiologically 18 mos. later
Reilly (1949)	2	Swelling face, fever, diarrhœa	Mandible, ribs, long bones, pelvis	Face, limbs	+	+	+	Generalised lymphadenitis	Residual broadening some bones at 15 mos.

* Erythrocyte-sedimentation rate raised.

DISCUSSION

The sudden onset of severe abdominal pain with no history of backache or stiffness and the severe anæmia were responsible for the initial failure to recognise this case of spondylitis ankylopoietica. On full consideration it was typical, not only in the patient's age and sex but also in the root pains, anorexia, and debility. The pains were never "girdle pains"; in the earlier stages they might have been interpreted as due to peptic ulceration, and later they were wrongly interpreted as due to a renal lesion.

A mild microcytic hypochromic anæmia is common in spondylitis ankylopoietica,[1] but a Hb as low as 36% is rare. There was no history or evidence of chronic blood-loss, and since the patient took both meat and green vegetables at his main daily meal, his iron intake should at least have reached the daily minimum of 5 mg. for a male. Unlike the failure of iron therapy in the anæmias associated with trauma or sepsis,[2] iron in this case was utilised as soon as it was given in large quantities, and before the patient had had any other treatment, beyond rest in bed and routine vitamin therapy. The defect seems to have lain either in a failure to assimilate iron or in an abnormal need for iron.

We wish to thank Dr. W. S. C. Copeman for his encouragement and permission to publish this case.

INFANTILE CORTICAL HYPEROSTOSES

MALCOLM MACGREGOR
M.D. Lond., M.R.C.P.
CHILDREN'S PHYSICIAN

ROSEMARY DAVIES
M.B. Lond.
CHILDREN'S REGISTRAR

SOUTH WARWICKSHIRE HOSPITAL GROUP

THERE are now 28 cases of infantile cortical hyperostoses on record, but the following example is only the second reported in England.

On Aug. 13, 1948, a 6-weeks-old male first-born infant was brought to an outpatient clinic in Nuneaton because he had recently developed a swelling above the left knee. This appeared not to be tender, and there was no history of trauma or of constitutional upset. Birth had been normal and the baby was being breast-fed. Cod-liver oil and orange juice had been given from the 4th week of life, when he had had bronchitis. He had gained weight well and was otherwise symptom-free.

Examination.—A diffuse but rather firm swelling was palpable deep in the tissues of the left thigh, which was slightly increased in girth. There was no reddening of the overlying skin, and manipulation of the lump appeared to cause no pain. X-ray examination on Aug. 16 showed a layer of periosteal thickening on the anterior and outer aspects of the left femoral shaft. No explanation for this was evident. In both mother and child the blood Wassermann and Kahn reactions were negative.

Progress.—At the end of August the swelling, though smaller, was still present. A radiological scrutiny of the entire skeleton was performed on Sept. 13. This time the changes in the left femur were more obvious (see figure); similar changes were found in the right femur, but all the other bones were normal. By November the soft-tissue swelling had vanished, but further radiographs on Nov. 11 showed that periosteal changes were more widespread and involved both femora in the whole length of their shafts, as well as the left humerus (see figure) and the proximal half of the left ulna. Mandible, clavicles, ribs, and scapulæ were unaffected. On Feb. 7, 1949, persisting periosteal changes were noted in both femora and the left humerus. On March 21 the white-cell count was 18,000 per c.mm. (polymorphs 25%, lymphocytes 70%, monocytes 4%, eosinophils 1%). By March 23 X-ray changes were becoming generally indefinite, and subperiosteal bone was merging with the cortical bone. Throughout this period the baby seemed to be in perfect health, and no further swellings became apparent.

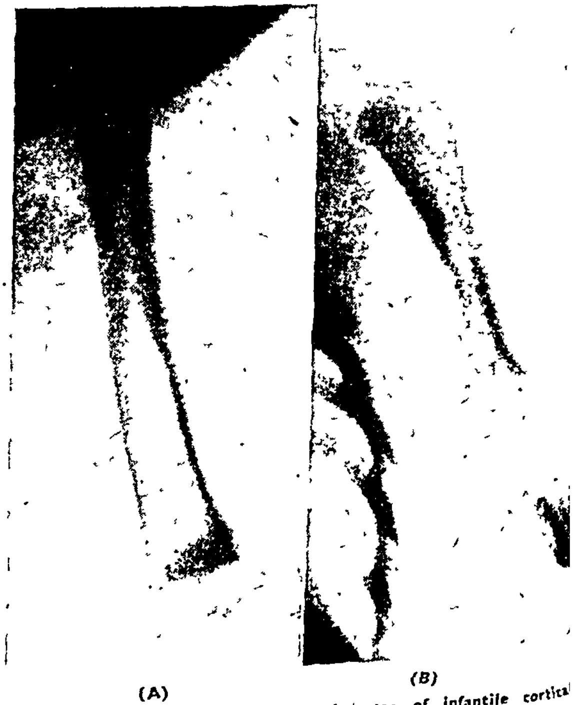
DISCUSSION

Attention was first drawn to the syndrome know the U.S.A. as infantile cortical hyperostoses by Ca and Silverman (1945) who described several ca The numerous subsequent reports of the condit nearly all of which have come from the U.S.A., summarised in the accompanying table; a case descri by Ellis (1939), which had certain resemblances to remainder, has been included.

From these accounts the following picture of the ill emerges. A young infant in good health abruptly devel a swelling of some part of the body—usually a l the face, or the neck. At this stage, there is o irritability and sometimes anorexia, but constituti disturbance is often slight and sometimes absent, the infant usually gains weight normally. The swel is palpable deep in the soft tissues; it is rather f but poorly outlined, and may be tender; but it is hot and the adjacent skin is not red. X-ray examina shows the formation of periosteal new bone envelopi part or the whole of the bone most nearly related the swelling, and involving also some other bones. bones most commonly affected are the mandib clavicles, ribs, scapulæ, and long bones of the lin and bones are often involved successively. Commo there is some fever, leucocytosis with a normal differen count, and hypochromic anæmia.

The disease is active for from 8 weeks to 9 mont but some X-ray changes may remain after this. disorder is benign, however, and all changes eventua disappear without after-effects. Biopsy of affected b shows simple hyperplasia of the cortex beneath an activ proliferating periosteum; on culture the area pro sterile. Bacterial infections, scurvy and rickets, traum and malignant disease have been satisfactorily exclud as the cause, which is still unexplained.

When swelling and tenderness of a limb are accompani by localised skeletal appearances such as have be described, the lesion may be mistaken for a trauma or infective one involving only one bone, unless oth bones are examined; and cases have probably be



(A) left femur, (B) left humerus in case of infantile cortical hyperostoses.

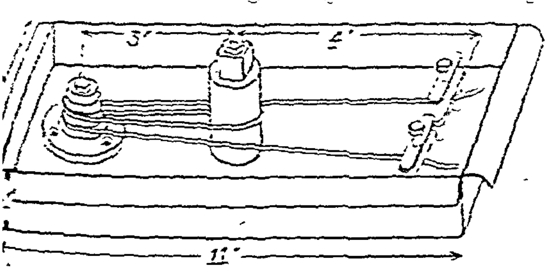
New Inventions

TERILISATION OF POLYTHENE TUBING FOR ANÆSTHETIC PURPOSES

introduction of continuous spinal epidural and analgesic methods requiring a plastic catheter raised certain difficulties. The apparatus for these ods was originally designed in the United States consisted essentially of a non-malleable steel needle—Tuohy needle—through which a length of plastic ng could be inserted, the needle then being with- rn. The tubing recommended is 'Vinylite,' but, so s I am aware, no similar tubing of the requisite size to withstand autoclaving is obtainable in this ntry.

t the Radcliffe Infirmary, Oxford, we have substi- d 'Polythene' tubing for vinylite. Polythene ng will withstand boiling though not autoclaving, but when it is boiled and then immersed in cold water it swells; the outer diameter increases at the expense of the length, and the tubing will no longer pass freely through the needle. Further, the tubing becomes kinked throughout its length.



To obviate these difficulties the following method of sterilising has been devised, the apparatus (see figure) being made for me by Mr. Richard Salt, of this department.

Before being sterilised the tubing is wound over a rounded block—e.g., an insulating terminal—and both free ends are held by screw clamps about 8 in. away. The tubing must be taut but not under tension, since the combination of heat and tension may cause rupture. After the tubing has been boiled, the tray is lifted from the steriliser and filled with cold water, since the tubing is easily damaged when softened by heat. The tubing is now cut free from the clamps with sterile scissors. With this method of sterilising, the tubing is not thickened and either of the straight ends can easily be threaded through the needle.

The apparatus is simple to make, the components being two porcelain insulating terminals 1–1½ inches in diameter, two screw clamps, such as are found in any transfusion apparatus, and a conveniently sized pan which will fit into a steriliser.

This apparatus may be obtained from Medical & Industrial Equipment Ltd., 12, New Cavendish Street, London, W.1.

Reviews of Books

G. Vaccination in Theory and Practice

K. NEVILLE IRVINE, M.A., D.M., medical superintendent, Smith Isolation Hospital; physician to the Henley War Memorial Hospital. Oxford: *Blackwell Scientific Publications. 1949. Pp. 130. 9s. 6d.*

ow that B.C.G. vaccination is being introduced in country, it is useful to have this handbook, which ables most of the information on the experimental , the technique, and the reported results. It is documented, and any serious student of the subject find in the references all the material for a more al study. Dr. Irvine gives a balanced account of istory and theory of this method of vaccination an informative chapter on the production of the ne. On the once much-debated subject of variations ulence, he concludes, after a good review of the nce, that since about 1930 it has been impossible ural methods to produce a return of dangerous nce to B.C.G. The techniques of vaccination are described; he favours the multiple-puncture ol.

eviewing evidence of the value of B.C.G., Dr. Irvine less certain ground. The chapter on the resistance ced in animals is satisfactory, but that on resistance an is not beyond reproach: he gives the main nces and quotes the results, but his own interpre- n of those results is uncritical. Thus he quotes t comment some very high morbidity figures in inated people—figures far higher than any observed at Britain after primary infection. Detailed reading of the work cited shows that the term "mor- is applied to many cases which cannot fairly nsidered to merit it. In his "world survey" of vaccination he gives little prominence to the fact n the United States it has been decided to advise the vaccine only for persons heavily exposed to ulosis. An uncritical approach is also suggested is statement that "in parts of Poland and Czecho- akia as many as 50% of the children are said to evidence of tuberculosis"—which clearly meant. ally, that half the children were tuberculin-positive. these minor defects Dr. Irvine's book is a ble and welcome work of reference.

Medullary Nailing of Küntscher

LORENZ BÖHLER, M.D., director of the Hospital for Accidents, Vienna; professor of surgery, University of Vienna. London: Baillière, Tindall & Cox. 1948. Pp. 386. 38s. 6d.

A REALLY new method of treating fractures is so rare that Küntscher's introduction of the medullary nail in 1940 naturally evoked a wave of enthusiasm; but for various reasons medullary nailing has never achieved or retained in English-speaking countries the instant popularity it won in Europe. Hence orthopædic surgeons in England and America—who owe so much already to Professor Böhler, and appreciate the frankness and honesty of his statements—will be glad to have this critical appraisal of the place of the medullary nail in the treatment of every kind of shaft fracture of the long bones. The work is published as an independent third volume of his famous treatise on fractures, and is faithfully translated by a former assistant, Dr. Hans Tretter, now of New Jersey.

Böhler himself was greatly impressed by the method. "It became immediately evident to me," he says, "that he [Küntscher] had found the technique for the treatment of properly selected shaft fractures of long bones . . . a method for which I had been waiting a long time . . ." But the key words here are "properly selected," and we are given the usual trenchant Böhlerian dicta laying down precisely just which fractures are to be nailed, and which not, and the dangers and contra-indications of the method in general. We are reminded that shocked patients do not stand the operation well, that the peace of the dying should not be disturbed by hammer blows, and that hour-long wrestling matches are to be avoided. He holds that closed nailing is indicated mainly for transverse fractures of the middle third of the femur, and for localised osteitis fibrosa-cystica of this bone; and open nailing only for fresh compound fractures of the femur and for old femoral malunions and pseudarthroses. In all other cases the disadvantages outweigh the advantages, and disasters of one kind or another are never far away. Nevertheless he gives a clear account of the operative technique for the nailing of every long bone; and the book can be used, if so desired, as a reference volume for just this purpose. He employs fluoroscopy during reduction and nailing far more freely than would be welcome in this country.

overlooked by omitting radiological examination of other parts of the skeleton.

D.D.T. POISONING IN MAN

A SUSPECTED CASE

A. M. G. CAMPBELL
M.A., D.M. Oxfd, M.R.C.P.
PHYSICIAN, BRISTOL ROYAL HOSPITAL

THE use of 2, 2 bis (p-chlorphenyl) 1, 1, 1. trichlorethane (D.D.T.) as an insecticide has become so general, and toxic symptoms in man have been recorded so rarely, that it is thought worth recording another possible case.

In poisoning by D.D.T. in animals the main toxic effects seem to fall on the liver and sometimes produce hepatic necrosis. The kidneys are also affected. There are loss of weight and ill-defined damage of the nervous system, accompanied by convulsions and sometimes damage to the anterior-horn cells (Draize et al. 1944, Woodard et al. 1944).

Wigglesworth (1945) recorded the first case of D.D.T. poisoning in man. The victim had been exposed to a high concentration of D.D.T. in acetone and had obviously absorbed much through the skin. He complained of heaviness and aching in the limbs, sleeplessness, spasms of great nervous tension, extreme fatigue, prostration, and twitching of the muscles over the whole body. For a long time his symptoms were thought to be due to a neurosis, until it was recognised that he had run the risk of absorbing a great deal of D.D.T. and this might be their cause.

Case (1945) found that Service personnel exposed to a high concentration of D.D.T. were liable to have fatigue, aching of the limbs, irritability, emotional instability, and violent cramp in the limbs. This finding suggests that the symptoms in Wigglesworth's (1945) cases were genuinely due to D.D.T. despite their resemblance to an anxiety state. Case mentions that one person, who was not hypochondriacal, was so prostrated that he had to take to his bed. Among other symptoms noted by Case were "yellow vision" in one person and diminution in auditory acuity in another.

The most striking feature in man has been the mental symptoms, and the following case is no exception.

CASE-RECORD

A man, aged 32, who had been a demonstrator of D.D.T. powder for the Ministry of Agriculture for six years, had handled and inhaled the powder, but not to the extent of what is generally thought to be a toxic hazard. His previous history was perfectly normal and, so far as can be ascertained, he had been free from any nervous breakdown or temperamental difficulty. About three months before consulting a doctor he had noticed periods of extreme fatigue and prostration while walking. He often felt an intense desire to sit down and an inability to take any exercise without a rest. He had noticed a tendency to emotional instability and weeping, and at the same time was getting cramping pains in his limbs varying from day to day and from limb to limb. The pain lasted twenty minutes on one occasion and three or four hours on another.

On examination no abnormality in his central nervous system was found except a slight tremor of the outstretched hands, and his performance of mental tests was good. lipomata were found on the left thigh; these the p had not previously noticed. Polyps were found i maxillary antrum.

Investigations.—The blood picture was normal. A b count gave red cells 5,000,000 per c.mm., Hb 107%, cells 9,200 per c.mm. (differential count and platelets nor The erythrocyte-sedimentation rate (E.S.R.) was 24 m 1 hr. (Wintrobe). A urea-clearance test and straight r graphy of the kidneys were normal. The urine cont albumin, red cells, and granular casts. The blood was 38 mg. per 100 ml. Lumbar puncture produced n cerebrospinal fluid under a pressure of 120 mm. H_2O, taining 2 lymphocytes per c.mm. and 30 mg. of protei 100 ml. The Wassermann reaction was negative. fasting venous blood-sugar was 90 mg. per 100 ml. The b lead was normal, serum-sodium 335 mg. per 100 ml., se potassium 17 mg. per 100 ml., serum calcium 9·7 mg. pe ml., plasma-chloride 626 mg. per 100 ml. (as sodium chlo plasma-bicarbonate 56 vols. % (as CO_2-combining po plasma inorganic phosphorus 3·7 mg. per 100 ml., and pla protein 6·7 g. per 100 ml. All these figures are within no limits All liver-function tests were normal, as lik were an electro-encephalogram, an electrocardiogram, a radiogram of the skull.

Treatment and Progress.—The lipomata were removed the thigh. The patient made a complete recovery cramps and weakness, and after a fortnight in hospital discharged with slight feelings of nervous tension, albumi (the red cells and casts had disappeared), and an E.S. 12 mm. in 1 hr.

DISCUSSION

Extreme mental fatigue and anxiety, cramps, tremor have been reported in all human cases of D. poisoning so far published. Weakness and ner tension have also been observed in D.D.T. poisonin some animals (Woodard et al. 1944). Since D.D.T. been thought to produce hypoglycæmia in animals to decrease liver glycogen, the fatigue may possibl related to a lowering of blood-sugar (Judah 1949). was not shown in the present case.

The mental symptoms may be due to the di effects of D.D.T. on the brain. Philips and Gilman (19 showed that curarised animals injected with le doses of D.D.T. had convulsive seizures, as shown electro-encephalography. Whether this action is du an upset of enzyme activity connected with tis respiration is not known.

Pathological and biochemical investigations in t case were strikingly normal, except for the finding casts and red cells in the urine. It is impossible to whether this renal damage and the raised E.S.R. w caused by D.D.T. poisoning. In animals, especia rabbits, renal damage and nephritis have b reported.

A lowered blood-calcium level has been reported some cases of D.D.T. poisoning in animals, but in t present patient the blood-calcium level was normal.

Though it is impossible to ascribe the present patien symptoms with certainty to D.D.T., the facts that had worked with D.D.T. fairly intimately for six ye and that his symptoms agreed so closely with th previously observed in D.D.T. poisoning make this t most likely diagnosis.

A periodical medical examination of all persons work regularly with D.D.T. is advisable. Judah (1949) h confirmed experimentally that calcium gluconate affor partial protection against D.D.T. intoxication.

'ANAHÆMIN' The *established* treatment for pernicious and other macrocytic anæmias

EVIDENCE is accumulating that the therapeutic action of liver extract in pernicious anæmia depends upon the presence, not only of a primary factor, vitamin B_{12}, but upon the presence also of accessory factors (*J. Clin. Invest.*, 1949, 28, 791). For most cases of pernicious anæmia, therefore, whether complicated with subacute combined degeneration of the cord or not, Anahæmin is recognised as the preparation for effective treatment; this is acknowledged by the pre-eminent position it has held for more than a decade. Every batch of Anahæmin is clinically tested before issue.

'ANACOBIN' Solution of PURE crystalline vitamin B_{12}

Occasionally, cases of pernicious anæmia arise which cannot be treated satisfactorily, even with Anahæmin, because of hypersensitivity. For such cases Anacobin is available.

THE GENTLE GIANT

'Albucid' Soluble in Ocular Therapeutics

FOR TISSUE of the highest sensitivity it is essential that local chemotherapy be effected by agents free from irritation. 'Albucid' Soluble Eye Drops are adjusted to pH 7.4 and are thus free from irritating alkalinity. High therapeutic efficiency, combined with ready solubility and very low toxicity, makes 'Albucid' Soluble the agent of choice in most eye infections. 'Albucid' Soluble Eye Ointments, containing 'Albucid' Soluble in a neutral cream base, are available for the treatment of infections of the eye and lids, where a slower and more prolonged absorption may be considered advantageous.

This requirement is in itself an obstacle to the wide use of the method here, where it is mainly applied to fractures of the upper third of the femur, which lend themselves to open reduction and nailing under direct vision. It is evident, too, that intramedullary nailing can be given a fair trial only in a highly organised fracture service where the staff are familiar with exact reduction of limb fractures in traction apparatus and with operative fixation under conditions of the greatest security. There are not many such institutions in Britain; and Böhler does us—and our patients—a service in making it clear that the surgeon who embarks on an occasional nailing without being prepared for every possible complication is heading for trouble.

The People of Great Russia

GEOFFREY GORER; JOHN RICKMAN, M.D. London: Cresset Press. 1949. Pp. 236. 10s. 6d.

ANY contribution to the understanding of Russia is likely to benefit international attitudes today; but it is hard to say how much this book contributes. The first half consists of beautifully written sketches of Russian peasant life in 1916, by Dr. Rickman; the second is Mr. Gorer's anthropological study of the Great Russians in relation to national character, cultural pattern, and upbringing. The one really important scientific contribution which this joint authorship produces is Mr. Gorer's suggestion that the practice of infant swaddling, which has never been studied fully in terms of psychodynamics, can account for a great many features of Great Russian character structure. This interesting idea deserves careful study and documentation which, in this book, it unfortunately does not get. Mr. Gorer's data seem to come largely from interviews with a limited number of émigrès, and from Russian party publications; and neither he nor Dr. Rickman produce any first-hand data about conditions in contemporary post-Bolshevik Russia—where such gross economic and social changes as the collectivisation of farming and the suppression of the kulak peasant element have almost certainly altered the pattern seen by Dr. Rickman in 1916. Mr. Gorer ends with some large political generalisations about West–East relations, which lack the caution which traditionally accompanies scientific study. He claims attention far more for his originality as a tracer of broad outlines than by his capacity for painstaking factual research. In spite of the difficulties of penetrating the Iron Curtain, it should be possible to obtain better evidence (than that which Mr. Gorer presents) of the state of child upbringing in Soviet rural communities. In its final effect, the book both stimulates and disappoints.

L'hyperazotémie

dans les malformations des voies urinaires chez les enfants. G. LAURET, assistant d'urologie à la clinique médicale des Enfants Malades, Paris; H. BOISSIÈRE, assistant des Hôpitaux de Paris. Paris: Doin. 1949. Pp. 94. Fr. 450.

MUCH work has of late years been done in many countries on the congenital malformations of the urinary tract. Hardly any other group of surgical problems sets such technically difficult tasks to the surgeon, if he is to complete his investigations and begin his treatment at the very early age necessary to avoid irreparable damage to the excreting mechanism of the kidney.

This short but interesting book describes sixteen such cases. It is mainly concerned with the body chemistry as showing the original state of efficiency of the kidneys and, more important still, whether this efficiency is changing. To anyone who has worked on this subject it is hardly necessary to explain that in many of these children the condition was such that no conceivable surgery could set it right. In addition there were frequent refusals of operation and even of investigations. The most important clue to kidney action is, of course, the amount of urea in the blood, an increase of which the French call *hyperazotémie*. There is no exactly equivalent term in common use in this country, the word uræmia conveying the idea of an advanced and dangerous stage. The method of estimating the amount of urea is the well-known one employing sodium hypobromite, and samples are taken indifferently from the blood or the cerebrospinal fluid.

Throughout the book there is a typically Fren clarity in the account of the clinical, as well as t chemical, aspect of the cases. A distinction is dra between the increased blood-urea due to relieval blockage and that showing permanent destruction kidney substance. There is also a warning, the urgen of which any surgeon experienced in such cases w appreciate, about the deceptive state of apparent heal that may coexist with a raised blood-urea. In such cas the slightest surgical stimulus may precipitate a fat uræmia.

This book is not of primary importance, but it very well worth studying.

Documenta Ophthalmologica (Vol. III. The Hagu Dr. W. Junk. 1949. Pp. 327.).—The third of these volum of collected monographs recording advances in ophthalmolo is edited, like its predecessors, by F. P. Fischer, A. J. Schæff and Arnold Sorsby. This time the contents include mo of the papers read at the conference on colour-vision held Cambridge in 1947. The sixteen contributions are all English; they include one by Selig Hecht, whose death commemorated in an appreciation by Hamilton Hartridg The present state of the trichromatic theory is discussed W. D. Wright, the polychromatic theory by Hartridge, t laminar pattern of the lateral geniculate nucleus by W. Le Gros Clark, increment thresholds and the mechanism of colour-vision by W. S. Stiles, colour-vision in t central fovea by E. N. Willmer, and the analysis of retin elements by the micro-electrode techniques by Ragn Granit.

Fractures and Dislocations in General Practic (2nd ed. London: H. K. Lewis. Pp. 290. 21s.).—M W. D. Coltart, who has revised Mr. John Hosford's boo admits in his preface that any improvement in the treatmen of fractures is due to the development of organised service Since these take such cases out of the hands of gener practitioners, the value of a book of this kind is open t question. The doctor who likes to know about the technica procedures of others may enjoy it, but it might have bee more useful to stress the ways in which his initial managemen of the fracture case can decisively influence the end-resul of the specialist's treatment. He may miss a fracture b taking a fractured scaphoid for a sprained wrist, or a broke femoral neck for a bruised hip—instances where delay has malign influence on outcome. He may fail to take seriousl enough complaints made by patients after their return hom in plaster, though these may be warnings of vascular stasi or pressure necrosis. Above all, he may not insist on th everyday use and exercise of the fractured limb in plaste so vital for restoration of function. These—which should b the cardinal points in a little book of this kind—are onl to be found embedded in a mass of material more appropriat for undergraduates. The detail itself is excellent, thoug there is no mention of the invaluable Capener nail fo trochanteric fractures, and the ritual of reduction and plaste is still advised for vertebral fractures.

Doctors East and Doctors West (London: Allen & Unwin. 1949. Pp. 278. 12s. 6d.).—Dr. Edward Hume tells with considerable skill, the story of his work in laying the foundations of a Yale-in-China hospital, medical school, and training centre for nurses. Very gradually, overcoming the distrust of a suspicious and conservative people, he sur mounted immense difficulties. A disused rice store became school, and an old inn with a fine range of outhouses use for fattening pigs was transformed into a hospital a dispensary. From this beginning, in 1906, in the old walle city of Changsha development proceeded apace. That i was made possible was very clearly due to Dr. Hume careful and appreciative understanding of Chinese cus and traditions, as well as of Chinese medicine. Helped by his native assistant he learned to win the confidence and friendship of Eastern minds. Treatment by Chinese doctors of the old school, he found, was often not without success. When, long before the establishment of liver therapy in the west, Sir Patrick Manson, in Amoy, failed to benefit a patient with pernicious anæmia by his treatment, he was astonished by the success with which the case was later treated by a Chinese doctor. The prescription was for continuous and large doses of crow's liver. Goitre was successfully treated with extract of seaweed, and the livers of fat fish were prescribed for tuberculosis. Both for its picture of Chinese ways of life and for its description of Chinese medicine the book is of great interest.

LONDON: SATURDAY, DEC. 24, 1949

Nutrition and Infection

ERY mother of a family, and every doctor in tice, firmly believes that the best bulwark against tion is good wholesome food. The association of rculosis with poverty and malnutrition is par- arly noteworthy. DANIELS,[1] in his Milroy lectures, rds that in the late war the countries with the st incidence of tuberculosis were those that red the greatest privations and food shortages. as HOWIE[2] points out, other factors besides ition may well have been involved. The poorly community often suffers from fatigue, low morale, iety, overcrowding, and poor hygiene, and its pital and public-health organisations are likely to lefective. Moreover, in spite of the appallingly nutritional standards in Germany at the end of war there were no major epidemics. Then again, lren brought up in apparently admirable living dietary conditions still contact measles, chicken- mumps, and poliomyelitis, and well-fed adults h colds and influenza. Poliomyelitis, indeed, s to have a predilection for young adults in llent physical condition; and the incidence appears e much higher in well-fed countries like the ed States than in, for example, the ill- ished African. It is understandable, therefore, most bacteriologists hesitate to accept the view malnutrition increases susceptibility to infection. he influence of heredity, both in the host and in infecting organism, cannot be overlooked. STER,[3] in New York, by inbreeding and selecting a common stock of mice, bred two strains h were widely divergent in their response to tion with *Salmonella enteritidis*, one strain being st completely immune to a given infective dose, other suffering almost a 100% mortality. Such eding and selection, however, did not produce tance to other organisms. The influence of dity in human infections is illustrated in the ies of KALLMAN and REISNER,[4] who showed that ne of twins over fourteen years of age has rculosis, the chances against the other contracting disease are 3 to 10 if it is a binovular twin but 9 to 10 if it is monovular (identical). SCHNEIDER[5] inguishes three types of hosts and pathogens sts that are inbred and resistant, inbred and ptible, or non-selected: pathogens that are ormly virulent, uniformly avirulent, or a mixture these. Thus host and pathogen can meet in 3 = 9 different ways. Add to this the nutritional factor of host and pathogen and the complexity of the problem is apparent.

If nutrition plays a part in the resistance to infection, one type of defence mechanism that one would expect to be affected would be antibody production, particularly as antibodies are derived from the serum proteins, which are lowered in frank malnutrition. At the end of the late war GELL[6] had an exceptional opportunity for studying the correlation between protein deficiency and antibody response. The subjects of his study were patients and prisoners from the Ruhr suffering from malnutrition—they were on a diet of only 1000 calories daily. Their antibody response, as measured by agglutination tests, was determined before and after infection with a rather bizarre mixture of tobacco mosaic virus and avian red cells, which were specially chosen because none of the subjects could have had any preformed latent immunity to them. British troops served as controls. The results showed that the well-nourished British soldier had a better antibody response than the half-starved German, but the differences, though statistically significant, were by no means as great as might be anticipated. GELL himself was astonished that they were so slight, and he concluded that "under-nutrition does not play as large a part in widespread epidemics as is generally supposed."

At one time vitamin C was thought to be associated with immunity mechanisms in the body, but the evidence is not very convincing. The early work indicating a direct correlation between blood vitamin-C levels and complement formation has not been confirmed. DEENY and his colleagues,[7] in Northern Ireland, could not establish any relationship between blood vitamin C and complement values in health or disease, and CRANDON,[8] the American research-worker who lived for six months on a diet devoid of vitamin C, had normal complement titres even at the time when he developed clinical scurvy, and he remained free from infection during the whole six months. On the other hand, the controlled experiment of GLAZEBROOK and SCOTT THOMSON,[9] in 1938 seemed to show a definite increase in the resistance of schoolboys against tonsillitis, pneumonia, and acute rheumatism—but not colds—when they were given full doses of vitamin C. There is some evidence that vitamin C is bacteriostatic, but only in concentrations that could never be reached in the blood and tissues. Even large doses of vitamin C intravenously do not increase the bactericidal power of human blood, though they are said to produce a leucocytosis. Large quantities of vitamin C are often given to patients with infections because their excretion of the vitamin is diminished, but whether the vitamin-C level in the tissues and blood of the normal person affects his susceptibility to infection or affects the virulence of the attack remains to be proved. Vitamin A has acquired the sobriquet of "anti-infective vitamin," without very firm evidence to support it, though HOWIE[2] quotes the experiment in which GREEN and colleagues[10] gave supplements of vitamins A and D to alternate women at Sheffield antenatal clinics, and found that

for Calcium deficiency in

PREGNANCY
LACTATION
DENTAL CARIES
RICKETS
URTICARIA

When calcium reserves are depleted, restoration of correct metabolism can be effected by the administration of Calcydic Tablets.

Calcydic Tablets are indicated in all conditions in which there is a deficiency of calcium, and when it is anticipated that extra demands will be made on the calcium reserves.

Calcydic Tablets are chocolate coated and present calcium in the readily assimilable form of calcium monoacid phosphate. Each Calcydic Tablet provides approximately 47 mg. of calcium, 37 mg. of phosphorus, and 500 units of vitamin D.

ALLEN & HANBURYS LTD. LONDON E.2

TELEPHONE: BISHOPSGATE 3201 (12 LINES). TELEGRAMS: "GREENBURYS, BETH, LONDON"

d this date variously between 1800 B.C. and 1. This radiocarbon method gives the actual age . rather than their age relative to that of surroundings, but 30.000 years does not take us anywhere near the period of such relics as those lown and Swanscombe. It might be applicable Galley Hill skeleton (now considered to be e than 10.000 years old). but a large amount material would have to be sacrificed.

the British Museum (Natural History). in oration with the Department of the Government ist, has devised a method which can be applied e relative dating of bones. This depends on ct that most water draining through the subsoil ins traces of fluorine. which combines with m phosphate in the bones. The fluorine content nes as a clue to their age was discussed by LETON[10] over a hundred years ago. CARNOT[11] d by analysis that the fluorine content increased age. though owing to the different fluorine nts of the water in different localities the actual f the bones could not be determined. Lately. ver. OAKLEY[12] pointed out that the method e used for deciding whether any given bone is e same age as other bones associated with it—their relative age. This method has now been ed to Galley Hill man and Swanscombe man. OAKLEY and ASHLEY MONTAGU[13] have shown the Galley Hill remains. far from being Middle ocene, are from a comparatively recent burial, as the antiquity of the Swanscombe skull is med. The fluorine content of Middle Pleistocene (2·0%) was five times as great as that of Galley nan (0·4%) but the same as that of Swanscombe The fluorine content of the Piltdown remains lso been examined. with the following result: l bones of undoubted Lower Pleistocene age all a high content, those of later Pleistocene age l in the same bed a much lower content. and ominoid remains an extremely small one.[14] So thropus must relinquish all pretensions to being Man. But even if he disappears in that rôle nust be looked upon as a late aberration. tools of remain which date back nearly a million years.

Treatment of Polycythæmia Vera

lycythæmia vera is generally thought of as a e coming on in late middle age and disabling r than fatal. Some of the patients live for almost normal expectation of years. but a recent survey the Mayo Clinic showed that. in fact. only 36 out of atients survived after more than five years.[15] The toms of headache and fatigue are troublesome: ymptoms produced by the enlargement of the n, by the tendency to peptic ulcer. and par- arly by the occurrence of thromboses may be us. So. ever since polycythæmia vera was first guished by VAQUEZ and by OSLER about fifty ago. attempts have been made to treat the e. and the methods used have all aimed at reducing the level of red cells and hæmoglobin in the blood to normal. Many treatments have had a temporary vogue. Phenylhydrazine certainly reduced the red cells and hæmoglobin and was easy to give: but its action was difficult to control—it had a cumulative effect on the bone-marrow that was liable to replace the polycythæmia by an irreversible aplastic anæmia. Radiotherapy has been much more successful. The X rays are applied in a localised manner to the enlarged spleen or to various long bones in turn, but RICHARDSON and ROBBINS[16] considered that whole-body irradiation gave superior results and reported on 28 patients so treated. Venesection alone has been used for years: it will control the symptoms for a while. especially in the younger patients who have had no thromboses and whose platelet-count is normal. But sooner or later venesection fails to reduce the circulating red-cell mass, and this state of affairs is sometimes shown by a fall in hæmoglobin without a corresponding reduction in red cells. Venesection is always likely to have its place in any scheme of treatment and is especially useful for quick relief of symptoms. Nitrogen mustards have been tried for polycythæmia. but the results have not been encouraging.[17] A suggestion from Egypt[18] that artificial infection with ankylostoma will control polycythæmia is unlikely to be pursued very far. in temperate climates at least.

Of the recent means of treatment. radiophosphorus (P^{32}) is. in LAWRENCE's view. far and away the most useful: he has been using radiophosphorus for ten years and in a recent survey[19] gives much evidence to support his opinion. The radiophosphorus is given intravenously in the form of a radioactive sodium phosphate. and a " course " of treatment varies from 3 to 6 millicuries according to the severity of the disease. Of his 121 patients most (86%) had been treated in other ways before having P^{32}: the average age of the series was 50·7 years. but the ages ranged from 19 to 75. For diagnosis an initial red-cell count of 7 million per c.mm. at least was required: immature white cells, mostly myelocytes, were found in the blood of 38% of the patients. and 69% of these had received previous treatment. Hypertension was noted in 33%. peptic ulcer was present in 11%. and 15% of the patients had had some form of thrombosis. It soon became clear that a single course of P^{32} would control some patients for long periods. In the first four years 30 patients received radiophosphorus, and since then these patients have, on average. needed a further course every three years: of the patients treated in the first five years 28% have needed only one course and have gone four to eight years without fresh treatment. There is some evidence that P^{32} reduces the incidence of thrombosis: this complication occurred in about 4% of the patients. whereas the average incidence with other forms of treatment has been about 25%: LAWRENCE relates this improvement to the ability of P^{32} treatment to keep red cells, hæmoglobin. blood-platelets. and blood viscosity all within normal limits. Of the 121 patients 21 have died, and 5 of these died from chronic or acute myelogenous leukæmia. Radiophosphorus has

the subsequent incidences of puerperal pyrexia were 19·2% in the vitamin group and 30·9% in the controls, while the corresponding incidences of severe sepsis were 1·5% and 3·6%. As HOWIE remarks, we need more human experiments of this kind.

Much work has been done in the last decade on the effect of nutrition in experimental infections in animals. Most of it is not applicable to man, and the great diversity of experiments, often inadequately controlled, present such confusing and at times conflicting results that it is difficult to draw any general conclusions from them. Experimental work on viruses, however, has established that the virus and the cells of its host compete for nutrients that are essential for vital enzyme mechanisms in both. If the virus prevents the host cells from utilising these essential nutrients, and appropriates them for its own purposes, then the host cells will suffer and may eventually die. Conversely, if the virus is starved of some of its essential nutrients it cannot live. Viruses thrive best in tissues whose metabolism is active—as in the developing hen's egg—and the typical picture of several virus diseases in animals can be markedly altered by a variety of dietary deficiencies.' Animals on diets deficient in members of the vitamin-B complex, such as thiamine, pantothenic acid, and riboflavine, often show a heightened resistance to some viruses, such as that of poliomyelitis, so that if they do become infected the disease runs a mild course. This and the low incidence of poliomyelitis among poorly nourished people may be examples of "starving out the virus." With bacterial and protozoal infections a deficiency in vitamin-B complex generally increases susceptibility to infection. Lack of some members of the B complex—for example, folic acid—produces leucopenia, which interferes with phagocytosis. Pyridoxine deficiency inhibits protein synthesis and might therefore conceivably affect the formation of antibody globulin. Interesting as these experimental observations are, we must guard against the assumption that they have an immediate application to human problems. Nevertheless, HOWIE [8] suggests that experiments on mice "offer the best hope of giving shape to the present vague mass of information."

The Age of Bones

IN the past the dating of fossil human bones has chiefly been based on studies of the geological strata in which they lay and the associated fauna, flora (pollen-analysis and dendrochronology), and impedimenta (mostly tools and pottery). But the question always arises whether human bones belong to the same epoch as the environment in which they are found or whether they have been introduced afterwards by burial or otherwise. When, as is often the case, the bones are found in a quarry, it is usually impossible to look for the disturbance of overlying strata which will show that they were buried, because these strata have been quarried away before the bones were discovered. Apart from burial, bones of man and lower animals may be washed out of their original stratum and deposited by the stream at quite a different level. An example of burial is the skeleton of Galley Hill man found in North Kent by ROBERT ELLIOTT in 1888,[1] and an example of stream-borne intrusion is the Piltdown remains found in 1908 by CHARLES DAWSON. At the time of their discov the Galley Hill and Piltdown remains appeared to among the oldest known bones of man, yet some their features seemed remarkably modern, a which was more disturbing when most anthropolog thought that modern man had evolved from Ne derthal man. Sir ARTHUR KEITH said that Gal Hill man was "Chellean" and had been buried an older stratum from a more recent land-surface but he thought that the Piltdown remains w possibly Pliocene,[3] and they were raised to the sta of a new genus, *Eoanthropus* ("Dawn Man"). bitter wordy warfare followed and lasted for ye between anthropologists who agreed and who agreed with his views. Then in 1935 MARSTON covered at Swanscombe, in a pit near that of Gal Hill, a skull which he considered to be of "relativ early Acheulean man"—i.e., later than "Chellea but still older than Neanderthal man—though t skull contained many modern features besides so primitive traits. So it became even more imperati to find out the age of the bones relative to the stra in which they were embedded.

The age of fossil bones cannot be estimated fr the apparent amount of fossilisation or mineralisati they have undergone. As Sir ARTHUR KEITH [4] point out, when bones become impregnated with iron sa fossilisation takes place extremely rapidly. A MARSTON [5] wrote:

> "In comparing the degree of mineralisation of bone, full allowance must be made for the natur the deposits which contained the bone. The authen cated report of the petrified condition of a body whi was exhumed for reburial six years after it had be buried in a 'cement-lime' formation in Nevada show that wholly unexpected and astonishing phenome of a physico-chemical character can occur in sh periods of time. . . . Weight and hardness afford infallible criteria of relative antiquity."

In America a method of dating fossil bones by the radiocarbon content has been worked out. From t study of cosmic rays LIBBY [6] concluded that neutro produced by cosmic radiation should form radi carbon. Subsequently ANDERSON et al.,[7] using met ane from sewage, proved that this was so, an suggested that the radiocarbon content could be us for dating carbonaceous material up to the age 30,000 years. The limiting factor is the short half-li of radiocarbon (about 5700 years). Thus after nea 12,000 years the amount of radiocarbon—originall extremely small—is reduced to a quarter, and so exponentially. The amount left after 30,000 yea would be too small for accurate estimation. So LIBB et al.[8] determined the radiocarbon content of sampl of ancient Egyptian timber of known date, and th means of their determinations agreed with th expected values within 1 standard deviation uni Their maximal error was about 450 years in a sampl aged 4600 years. Finally LIBBY [9] applied the metho to timber of unknown age in Peru and put its dat at 800 B.C. ± 200 years. Archæologists had previousl

Dr. McCleary says of the sixpenny :

> "Sometimes he was English: not infrequently he was ish; more rarely he was coloured; often he spoke an Irish accent. Usually he began with what was a 'nucleus' and if successful he would develop his into a lucrative practice, which he would sell and the proceeds buy a practice in a genteel suburb. . . ."

ny doctors worked exceedingly long hours, at speed, doing their own dispensing from stock es—for a bottle was a part of the bargain. imes they gave *Saccharum Ustum*, "a medicament possesses in a high degree what Hippocrates down as the first essential of medicine—that it should no harm." Dr. McCleary, who served as a locum in such practices, is cheerfully unrepentant about bottles of burnt sugar.

> "When I think of the vast quantities of heart-depressing drugs that are swallowed annually in self-medica- by an unreflecting public, I recall with satisfaction dispensing of *Saccharum Ustum* with its reassuring and complete harmlessness of effect."

he worked in a practice in North London where were two waiting-rooms, one for the sixpenny ts and another for those who could afford to pay shilling. The doctor saw two shilling patients for ry sixpenny patient, so the higher fee saved the ient a wait. The clientele in the two rooms varied rding to the ready money at their disposal at the e: there was no feeling of class distinction about it.

Dr. McCleary would not have us think these doctors re inefficient or careless:

> "Some of the men for whom I worked were skilled, onscientious, and laborious, who loved their work and did heir best for their patients. They had developed a time-aving technique and a flair for distinguishing the important rom the unimportant."

suggests that Flaubert might have made a classic the life of one of these doctors. Some will recall ess ambitious work—*Sixpenny Pieces*: the modest ute of Neil Lyons to Harry Roberts, in Stepney.

ADRENOCORTICOTROPIC HORMONE AND HYPERSENSITIVE REACTIONS

It is sometimes forgotten that the symptoms of disease produced not directly by the external or internal ious agent which is acting but by the body's reactions hat agent. Even when there is a definite bacterial or cause, the clinical picture—the malaise, fever, pain, local inflammation—is that of the body's attempt to bat the attacker. In some diseases, of which those ed allergic are the most striking example, though they include the rheumatic group, periarteritis nodosa, others—the body's reaction is out of all proportion the severity of the attack and is therefore called a ypersensitive" reaction. In these, if the reaction can abolished the "disease" is cured—at least for the being. A few years ago Hughes[1] suggested that in te rheumatism any "poison" which would abolish body's reactivity without doing any permanent m would produce a cure: in his view this explained action of salicylates in rheumatic fever.

The same principle—of treating disease by moderating body's reaction—is behind the use of antipyretics in eral, and of 'Cryogenine' in particular; and Dr. offrey Bourne showed in these columns last week that uction of temperature with this drug can improve e condition of patients with lymphadenoma, rheuma- id arthritis, or tuberculosis.

The vast amount of work being done in the U.S.A. th A.C.T.H. and 'Cortisone' suggests that one impor- nt effect of these substances is to block hypersensitive reactions. This may explain the observations made (though still unpublished) in a wide variety of diseases, that A.C.T.H. immediately abolishes the malaise associated with them; it may also be the basis of the good results reported by Hench and his co-workers[2] in rheumatoid arthritis and acute rheumatic fever. Moreover, Bordley and his colleagues[3] at Johns Hopkins have now reported remarkable results with A.C.T.H. in allergic diseases. The rapid recovery of a patient critically ill with exfoliative dermatitis due to iodine led them to try A.C.T.H. in a case of penicillin sensitivity of serum-disease type, in which the giant urticaria, joint pains, and fever disappeared within 24 hours. They then obtained equally rapid relief in five patients with severe chronic asthma which had not responded to adrenaline, theophylline and ethylenediamine, or rectal ether. In four of these the symptomatic improvement was accompanied by the return of a pale œdematous polypoid nasopharyngeal mucosa to an appearance not far from normal. In accordance with the experience in rheumatoid arthritis, the patients tended to relapse 2–3 weeks after their course of treatment.

THE "BURR" RED BLOOD-CELL

HÆMATOLOGISTS are familiar with the spherocyte, the round fat red cell of hæmolytic anæmia, and with the "target" cell, the thin red cell of Mediterranean anæmia, so thin that its sides clap together somewhere about the middle and make it look, in transmitted light, like a Scottish shield or target. Then there are the sickle-shaped cells associated with a familial anæmia in negroes, the oval cells which are also familial, and one or two other odd shapes of no particular diagnostic import have been described from time to time. The latest addition is the "burr" cell of Schwartz and Motto,[4] which is said to be found only in patients with certain diseases, particularly where kidney function is impaired.

The burr cell is a kind of poikilocyte. It is a red cell of normal size with one or more spiny projections along its edge; the projections are quite long, varying from about a sixth to half the diameter of the red cell, and photographs show that they are usually sharp and pointed. So it does vaguely resemble the burrs that stick to our clothes or the coats of our dogs. Burr cells are not just crenated cells; they are fairly evenly scattered over the blood-film, whereas crenated cells tend to accumulate in groups. The blunt-processed burr cell may well be difficult to distinguish from a crenated cell, so no cells should be counted as burr cells unless they are apart from crenated groups. Schwartz and Motto found burr cells in the blood particularly in cases of uræmia, carcinoma of the stomach, and bleeding peptic ulcer. Out of 75 uræmic patients 54 had burr cells in their blood smears; out of 50 with carcinoma of the stomach 34 had burr cells; and the cells were seen in 27 out of 50 patients with bleeding peptic ulcer. Two control series were studied; the first comprised 100 consecutive blood-films from patients admitted to the medical wards for some condition other than a blood disease; the second was made up of 100 patients who had some hæmatological abnormality. No burr cells at all were found in the first group, whereas 21 patients in the second group had them, and the only common factor in these 21 patients was renal impairment.

What it is that causes red cells to throw out spinous processes has not yet been determined. Severity of the anæmia, duration of bleeding, degree of nitrogen retention, dehydration, age, sex, and race, have all been not reduced the incidence of leukæmia in patients with polycythæmia vera, but on the other hand it has not increased it, as might have been anticipated; nor is there any evidence that this treatment has increased the subsequent incidence of neoplasms.

[4] Schwartz, S. O., Motto, S. A. *Amer. J. med. Sci.* 1949, 218, 563.

The average age of the patients treated with P^{32} who died was 67 years, and this is nearly the normal expectation of life for a group of average 50·7 years; it compares well with the expectation of life of patients with properly controlled pernicious anæmia or diabetes. Apart from P^{32}, the only other remedy used in this series was venesection, which was needed in rather less than half the patients to control urgent symptoms, since radiophosphorus takes several weeks to produce its full effect. These are very striking figures, the reduction of thromboses being the most important effect, and the one probably responsible for the notably increased expectation of life—and useful life at that. Other treatments have produced long remissions before, and they are not remarkable in such a chronic disease. We are not told how often the treatment was given to the 72% of patients treated in the first five years who did need more than one course, and LAWRENCE does not mention any failures—perhaps there were none.

In Belgium SIMON and HENRY [20] have given radiophosphorus by mouth to four patients with polycythæmia who had been ill for some years and deri no benefit from various other treatments. T patients were treated as outpatients. The rad phosphorus was given in fruit-juice on an em stomach, the initial dose being 6 millicuries, except one case in which the patient had previously underg radiotherapy, thus introducing the risk of excess reaction. A month later three of the patients w given a further 4 millicuries. The fourth patient w not given a further dose, because the blood pict had become normal. After eight months the blo pictures of all four patients were satisfactory and troublesome symptoms had disappeared.

It is clear that in polycythæmia vera radioph phorus has produced first-class results—its only real sustained therapeutic success. Proper precautio must be taken when handling P^{32}, and its short ha life of 14 days means that supplies must be availal at short notice; for clinics near one of the aton centres this may not be difficult to arrange. In t country supplies are controlled through the Medic Research Council,[21] and they are unlikely to ag to provide P^{32} unless they are satisfied that th who are handling the material will be prope protected. Nevertheless physicians here should now able to arrange for any suitable cases to ha this treatment.

Annotations

PREVALENCE OF CORONARY DISEASE

THE apparent increase in deaths from coronary disease in recent years, particularly among the younger age-groups, is a disturbing observation which the lay press has not been slow to publicise. The haste and competition of modern industrial life, with its train of frustration, anxiety, and mental fatigue, contrasted with the less exacting conditions "enjoyed or endured by our more slowly moving agricultural forebears," seems an obvious cause for increase, but Ryle and Russell,[1] from their clinical and epidemiological survey covering the last twenty-five years, show that this is by no means the whole story. Indeed, the Registrar-General's statistics reveal that the mortality from coronary disease is now increasing less rapidly than before the late war, that people are tending to live longer, and that a changing fashion in death certification may largely account for the figures. Because of the wider familiarity with the clinical features of coronary thrombosis and the improved facilities for confirming the diagnosis—e.g., by electrocardiography and necropsy study—many deaths previously certified as due to myocardial and cardiovascular degeneration are now specifically grouped under coronary disease. Nor is there any good evidence that cigarette smoking in the hard-pressed citizen of today bears any causative relation to the deaths from coronary disease, for non-smokers are not immune. The notable dominance of those occupations which involve much mental activity and responsibility is revealed in the decrease in mortality figures with descent in the social scale. This same socio-economic influence seems to explain why the death-rate from coronary disease is five times as great in middle-aged men as in women of the same age-group. Recent emphasis given to the incidence of coronary disease in young adults by the publication of cases which occurred in the Forces in the war [2] may have given an exaggerated picture, for when reviewed statistically coronary disease is very rare at or below the age of 35.

There is no condition in medicine where the progn is more difficult to assess. Heredity, age, occupati evidence of extensive arterial disease, or hypertens are only a few of the factors which have to be tak into account. Even when every feature of the case favourable, early sudden death may occur; yet converse is as often true, and Cassidy [3] reported on t patients who survived for more than 30 years. It see to be on the lines of prevention that the future n hold most hope, through periodic health examinati and the organised regulation of conditions of work personal leisure—always providing that these measu can be put into operation without interfering too m with individual freedom. But we cannot afford to ign the dietary factor, to which Dr. Closs and Dr. Dedic again draw attention in o -ndence colun this week. Evidence is hyp cholesterolæmia has a significant bearing on the ætiol of arteriosclerosis, and cholesterol metabolism can influenced by the amount of fat and protein in diet, by the lipotropic and oxytropic fractions of vitamin-B complex, and by thyroid extract. It is unreasonable to foresee a future enterprising Minis of Food paying closer attention to these compone of the nation's diet.

THE SIXPENNY CONSULTATION

THE sixpenny doctor has long been an almost fabul memory; and his modern equivalent vanished with coming of the National Health Service. But so remember him, among them Dr. G. F. McCleary, w has lately given us Some Medical Memories.[4] Sixpen practices were flourishing at the turn of the century in London slums, and many doctors went into them for mere purpose of making enough to get out. A f stayed and served their patients for the best part of lifetime, and their service was good even by mode

TAKING THE CURE

OBSERVATIONS AT SOME FRENCH SPAS

HE effect of Epsom salts has long been obtainable hout visiting Epsom ; and the modern English or erican doctor is disposed to think that his patient get all the benefits of spa treatment from a bottle, oliday, and perhaps some physical treatment in the patient department. With so many potent remedies is disposal, he has little use for the vaguer influences irs, waters, and places, and he mistrusts the elaborate rts of spa physicians to explain these influences in hemical terms. Though many of his own methods in fact just as empirical, he is apt to feel that spa tment, as such, belongs to the unscientific past.

nder its new scientific management, medicine of course be remarkably successful in dealing with able illness: the system provides investigation, tment, and reablement, after which the patient urns to work with the minimum of permanent dis-lity compatible with his original disease. But as our erest gradually turns to the vast residuum of chronic l degenerative disorders—cardiovascular, rheumatic, mentary, and psychological—the picture seems less ght. Not unnaturally, the doctor of today concerns self more with the diseases he can cure than with se he could at best relieve, and the very success of remedies where they are applicable favours thera-tic nihilism where they are not. The question will reasingly be asked whether hospital medicine as now ctised offers "chronic" patients anything as satisfy- as the annual cure which some of them formerly k at health resorts—the overhaul and assessment, l the three or four weeks of active treatment and t, during which they could go into the physical uivalent of a spiritual "retreat."

This religious parallel is the more relevant because many ways the spa is a survival or revival of the aples of healing where medicine was practised by ppocrates and his successors. As in the old days, medicinal waters are the centre of a medical organisa-n, with its priests and ministrants ; and, as in the days, the doctors have many aids at their disposal ides the actual waters. The patient may gain ch from his transfer to peaceful and pleasant surround-s; or from a change of climate ; or from the know-ge that he is having positive treatment ; or from the e of a physician with special experience of his com-int; or merely from the atmosphere of confidence hin the therapeutic temple.

The emphasis differs from place to place. There are s where it is all on the natural waters, and where ything combines to make the patient believe that he recover if he washes 21 times in Jordan, wing the precise rules prescribed. There are ers where the physicians have little faith waters of any kind, but offer instead the est equipment in their specialty. On the one nd there is the simple temple of healing, ch as it was when the Romans left it : on e other hand there is the modern Rheumapolis or Nephropolis, with its investigations complete as in any great hospital, and its atment even more elaborate. Likewise there e patients to whom one of these kinds of a is more useful than another.

In France, where medicine preserves more f its traditional pattern than in England, "the re" still takes a big place in the medical e of the people. Certain tendencies and differ-ces in its application will be evident from e following sketch of some of the principal French spas which were visited this summer by a party of English physicians led by Lord Moran.

Eight Examples

It will be seen that, like our own Bath, several of the spas of France were flourishing health resorts under the Romans ; indeed they were a characteristic feature of Gallo-Roman civilisation. Even their renaissance is of respectable antiquity, for already in 1604 Henri IV thought it necessary to appoint a *surintendant général des fontaines*, and for three centuries after that the care of medicinal springs was continued by official medical inspectors. The story of the last hundred years has been largely that of specialisation : instead of accepting patients of every kind, the various spas have tried to ascertain which disorders they particularly benefit, and why ; and to a greater or lesser extent all concentrate on particular diseases or diatheses. In so far as the differences between spas and their waters are significant, the policy of specialisation is justified and necessary : it naturally appeals to patients, who like to believe that a particular resort was designed by Heaven for the treatment of their particular malady : and it has made for progress in the development of individual methods. But some think this policy can be carried too far : the spa, they say, should not concern itself exclusively with the disorders of a single organ, but rather with the patient's general condition and functions, which a cure may be able to modify.[1]

Each of the following "thermal stations" has fairly definite indications of its own, though some of them overlap.

ROYAT

Emerging abundantly from the volcanic mountain plateau of the Auvergne in Central France, the waters of Royat-les-Bains are warm (up to 35°C) and contain much carbon dioxide both as bicarbonates and as free gas. They were used by the Romans, and in the Middle Ages ; but the present spa dates from the 1850s, and its specialisation in cardiovascular disorders from 1905. The waters have diuretic and other properties, but their principal use is in baths, designed to modify circulatory responses. Though the waters are employed in their natural form—they are seldom heated and never charged with additional gas—different physiological effects are obtainable with water from the different sources, and with water from the same source before and after storage, and also by giving baths of still or running water, with or without douches. Thus a bath in the water from the Eugénie source which has lost most of its free gas by storage, and has a temperature of 33–34°C, is vasodilator and hypotensive, whereas a bath in fresh gaseous Saint-Mart water at 28–29°C is stimulating and

Background to Royat.

---

[1] Chabrol, E. Doctrines thermales. Paris, 1936 ; p. 98.

considered and rejected. Hypoproteinæmia and the presence of blood in the intestinal tract may have something to do with it. Schwartz and Motto think that burr cells can be valuable signposts in the study of the anæmias, though in their patients the diagnoses seem all to have been well-established. Still, it does not take very long to look for burr cells and no special technique is needed —so hæmatologists will be on the look out for them.

THE FOOD WE EAT

IN each of the past ten years, we are told, the average calorie value of the food going into consumption in this country has been within 200 calories of the pre-war total of 3000 per head per day. This constancy is indeed remarkable; but it also shows how deceptive averages can be. For, as we all know, the effect of rationing, price control, and redistribution of incomes has been to spread food-supplies throughout the community more evenly than ever before. And the sources from which the calories are obtained have also altered.

In a sequel to earlier accounts[1] the Ministry of Food carries the story of our food consumption forward to June of this year.[2] The report puts the average daily calorie value of the food distributed in 1948 at 2890, and in 1948–49 at 2980. The Ministry's estimate of the weighted average requirement in 1948, based on American tables,[3] is 2560 calories. This average, unlike the first, is for food actually consumed. There's many a slip 'twixt the ship and the lip, and the Ministry's figure for food distributed takes no account of waste at the retailer's or in the household (apart from such obvious causes as potato peeling). This waste may amount to as much as 10% of the total; so we have no surfeit.

Taking pre-war annual average as 100, the recent civilian intake per head per day is as follows:

	1946	*1947*	*1948*	*1948–49*
Calories	96	96	96	99
Protein: Animal	104	101	96	95
Vegetable	124	128	125	128
Total	113	114	109	110
Fats from all sources	*86*	*81*	*83*	*81*
Carbohydrates	100	101	105	108

The following figures show, in percentages, the various sources of calories:

	Pre-war	*1946*	*1947*	*1948*	*1948–49*
Dairy products (excluding butter)	9	11	11	11	11
Meat (including canned meat and bacon)	17	13	12	11	10
Oils and fats (including butter)	17	11	13	15	15
Sugar and syrups	15	12	13	13	14
Potatoes	4	7	7	6	6
Grain products	30	35	36	37	36
Other foods	8	8	8	7	8
Total	100	100	100	100	100

By weight in lb. per head per annum the average consumption has been computed as follows:

	Pre-war	*1946*	*1947*	*1948* (provisional)	*1948–49* (provisional)
[illegible]	*38·3*	*49 4*	*48·7*	*49·0*	*50 6*
[illegible] bacon, and ham) (as edible weight)	109 6	89 9	82 0	73·8	69·8

In 1948–49 the distribution of fats was nearly [illegible] above the level for 1946, and butter (12·5 lb. in the y[illegible] *was at its highest level since the start of the war,* tho[illegible] still only half the pre-war total of 24·8 lb. Sugar (91·2 [illegible] was also higher than at any time since the start of [illegible] war, but was still substantially below the pre-war fi[illegible] of 109·9 lb. Since 1946 consumption of liquid milk [illegible] risen by 7%; *compared with before the war it has* r[illegible] by 55%, and consumption of dairy products as a w[illegible] by 30%. In terms of "shell-egg equivalent," the amo[illegible] distributed in 1948–49 was only 8% below the 193[illegible] level.

ARMS AND DISEASE

Timor mortis conturbat me, complained the p[illegible] Whoever stops to consider the number and press of [illegible] dead is liable to [illegible] it seems so dange[illegible] *to be alive.* P[illegible] who last Decem[illegible] began to recount the story of wars and epidemics, c[illegible] pleted it in his two final FitzPatrick lectures deliv[illegible] at the Royal College of Physicians this month. W[illegible] are not great killers compared with plagues; but [illegible] vast has been the toll taken by both together that [illegible] audience may well have felt some pride in their f[illegible] bears for surviving at all. They must have reflec[illegible] too, how very different our world—and even we ourse[illegible] —might have been but for sundry epidemics, tim[illegible] and untimely. Thus, when the Moslems set out to conq[illegible] the world, not arms but pestilence kept them at [illegible] Pestilence defeated the Crusaders, thinned populati[illegible] throughout Europe, led to vast massacres of Jews ([illegible] were accused of spreading the Black Death), helped [illegible] lose France for England, made the Emperor Charle[illegible] master of Italy, added to the horrors of the Th[illegible] Years War (which reduced the people to starv[illegible] degraded animals), turned Charles I from the co[illegible] which might have saved him, almost defeated [illegible] French Revolution, broke the power of Napoleon [illegible] Moscow, and gave birth to modern nursing. These [illegible] the main and obvious effects of epidemics; but t[illegible] lead the mind to speculate on its unknown stroke[illegible] to wonder what potential princes, poets, saints, scienti[illegible] tyrants, and dictators it has brought down. No do[illegible] things might have been better, but then they might h[illegible] been so much worse.

EDITORSHIP OF J.A.M.A.

FEW, if any, doctors can be so well known to so ma[illegible] people in so many countries as Dr. Morris Fishbein, edi[illegible] of the *Journal of the American Medical Association* [illegible] the beginning of this month. He joined the journ[illegible] quite temporarily, in 1913 as assistant to Dr. George [illegible] Simmons, and succeeded him in the chair in 1924. [illegible] editor in the dynamic American tradition, doing much [illegible] form as well as to express the policy of his associati[illegible] he has also done much to raise the technical standa[illegible] of medical writing. His production of the *Quarte[illegible] Cumulative Medical Index* is in itself a major contri[illegible] tion to medicine. But at the same time he has ma[illegible] himself one of the chief exponents of medicine to [illegible] American public—through his editorship of *Hyge[illegible]* and through books, lectures, and broadcasts. Many w[illegible] disagree with his opinions have come to feel ab[illegible] Morris Fishbein as Elliott Cutler did when he wro[illegible] "Of his intelligence I was long ago assured, but [illegible] constant turmoil of this recent publication led me [illegible] respect his ideals, his generosity, his patience and [illegible] ability."

Dr. Austin E. Smith, director of the A.M.A.'s di[illegible] sion of therapy and research, has now assumed editor[illegible] responsibility for the journal.

SIR HENRY COHEN, professor of medicine in t[illegible] University of Liverpool, has been appointed preside[illegible] elect of the British Medical Association in succession [illegible] the late Prof. T. P. McMurray.

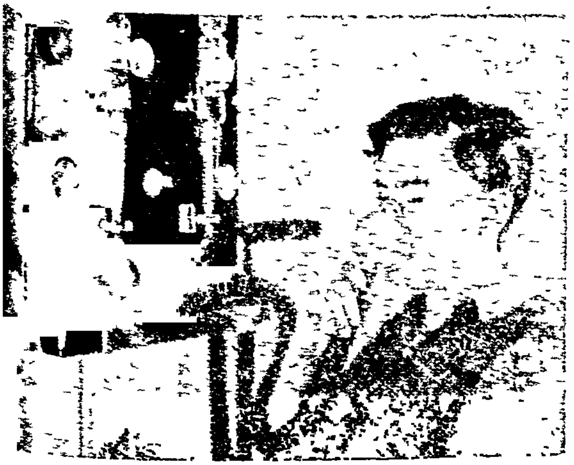
an antispasmodic action on the nervous system. they are also applied externally and topically by t variety of methods, and much of the equipment nebulisation (vapours), pulverisation (aerosols), douching, gargling, and bathing is so elaborate no patient could doubt its efficacy. Much attention to skin diseases, including acne, allergic reactions, , and eczema; and the filiform douche (a fine water delivered at very high pressure), which is in removing crusts and also in treating acne and was devised at La Bourboule. A salon for treatment has been opened.

adults the chief indications for treatment at this skin diseases, anæmias, catarrhs of the nose and bronchitis and asthma. In a small research nt the effect of treating bronchospasm with the waters in aerosol form is being tested by spiro- and a preliminary report claims that this effect rable with that of the bronchodilator drugs d elsewhere. The most characteristic feature Bourboule, however, is its use by children who for the treatment of catarrhs, bronchitis (non- lous), asthma, anæmia, skin disorders, and debility illness. Children unaccompanied by their parents special pensions or hostels, and have a carefully régime including rest periods and several each afternoon in a large "children's park," which at once a medical centre for physical culture and a lace of happily unregulated amusement on swings and erry-go-rounds or playing around a stream. It is tonishing to see so many children having so much fun t doing so little damage.



Inhaling aerosols at La Bourboule.

A golf-course (at 3900 ft.) can be reached by funicular ay, and the casino has a theatre. The season is from y 15 to Oct. 5.

SAINT-NECTAIRE

Though it has a casino and substantial medical tablishments, Saint-Nectaire is a much smaller, quieter, nd less sophisticated spa than those just described; nd the town itself is old and charming. Lying on the astern side of the Mont-Dore mountains at an altitude of me 2500 ft., it specialises in renal disorders, but also akes cases of anæmia, "lymphatism," and gynæcological omplaints.

The waters, coming from 24 sources at temperatures rom 8 to 56°C are various, some containing more carbonate, others more iron and arsenic. The Granges- ina water is used in renal disease for its diuretic roperties; the patients are given baths and douches; nd special diets (e.g., low in salt or in protein) are provided in the hotels and pensions. A special form of treatment practised at Saint-Nectaire is the hot lumbar douche. During the usual three weeks' treatment at the spa, renal function often shows remarkable improvement, and many patients are glad to return for a course each year. On the other hand it is clear that many of the miscellaneous conditions reaching Saint-Nectaire would improve without treatment, and the cure is justified by experience rather than by statistics.

Saint-Nectaire.

The season is from May 25 to Sept. 25.

VICHY

Vichy, Vicus Calidus, Little Paris, lying beside the River Allier at the very centre of France, 736 ft. above the sea, is a beautiful town, with as many trees as houses. Since the 17th century it has attracted the *beau monde* at home and abroad, and with some 130 consultants and specialists it remains in the first rank of medical and fashionable resorts. The only contra-indications to a cure at Vichy are stated to be neoplastic disease, peptic ulcer in the stage of evolution, and fevers (particularly active tuberculosis).[7] But the conditions for which the waters are deemed specially valuable are disorders of the liver, of the digestive tract, and of nutrition.

The waters, emerging at temperatures from 66°C downwards, are alkaline and sparkling, and have been elaborately studied, first chemically and then physically; but some of the qualities of a thermal water remain elusive, and the physicist gives moral support to the clinicians who claim that the "living" water at the spring is something different from the same water allowed to stand for a quarter of an hour—and a less powerful remedy.

> "A leading London physician . . . once said to me: 'After all, what about your Vichy cure? If I were to tell my patients to rise early, to frolic around Trafalgar Square and now and then to drink half a tumbler of water from the fountain, I am sure I should get the same results as you do.' 'Why not do it?' I answered. 'After all, only results count.'"[8]

Even apart from their more intangible properties, the waters of Vichy, like those of many other spas, have constituents that give them an obvious biochemical or pharmacological action; in excess, they can, for example, induce alkalosis. According to medical Vichy, they specially affect the functions of the liver, stimulating both its internal secretions and the secretion of bile. The patient with cholecystitis, with or without gall-stones, is likely to be helped by their cholagogue and other actions; and every kind of hepatitis, it is said, can benefit provided cell degeneration is not too far advanced; though of course there are conditions whose evolution

"cardiotonic." Though the water is cool, a sensation of warmth is imparted by the formation of innumerable bubbles which (unlike those of artificially aerated water) cling to the skin.

> "The patient appears clothed in a bathing suit of brilliant pearls; he immediately appreciates a sensation of prickling, or itching and of heat, and, meantime, the skin becomes red. . . . The bursting of the bubbles and their almost immediate reappearance gives rise to a series of recurring sensations of heat and cold, acting much like alternate douches, microscopic and of very high frequency."[2]

The Royat doctors hold that the carbon dioxide causes vasodilatation not only locally, by stimulating the skin, but also generally, via the central nervous system and otherwise, after absorption through the skin into the blood-stream.[3] An alternative method of getting this result is to give the patient a "dry bath" by putting him in a bag containing carbon dioxide, as first proposed in 1875. More recently improvement of the local circulation (e.g., for intermittent claudication and angina pectoris) has been sought by subcutaneous injections of gas from the thermal waters.[4–6]

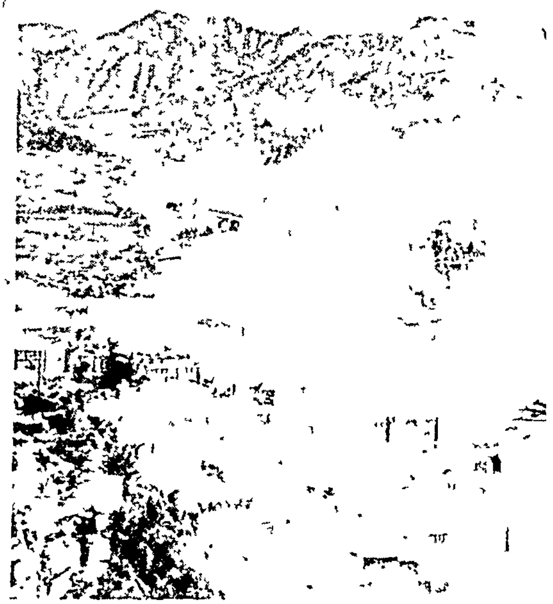
A great deal has been published on all this cardiovascular work, but admittedly some of the explanations are speculative. Much to be commended therefore is the enterprise of Royat, and M. Paulet, its mayor, in establishing an institute where the physiological problems are to be studied, under the direction of Professor Jourdan of Lyons. With equipment which is likely to be excellent, the investigators will be free to do whatever interests them most; but it is hoped that they will combine the clinical and experimental approach and make good use of the large material at their command. Slowly recovering from the difficulties of the war, the spa attracts an increasing number of patients with chronic cardiac and vascular disorders, including hypertension, many of whom are sure that an annual cure makes a big difference to their health and efficiency in the intervening eleven months.

At an altitude of 1480 ft., Royat stands on an outlying slope of the Auvergne, overlooking the semi-industrial city of Clermont-Ferrand and the fertile plain of the Limagne. Though almost contiguous with Clermont, it has a hinterland of fine mountain scenery, including, quite close, the Puy-de-Dome (4806 ft.) surmounted by an observatory and the ruins of a large temple of Mercury. It has an exciting golf-course, a large casino containing a theatre, pleasant gardens, and many hotels, of which at least one is superlatively good. The "season" is from April 15 to Oct. 15.

MONT-DORE

With its 80 hotels and pensions, Mont-Dore (3400 ft.) lies in a wooded valley in the heart of the Auvergne, dominated by the Pic du Sancy (6188 ft.) the highest point in Central France. It was a Roman health resort, with a temple; Jean Banc in 1605 was astonished to find traces of the conquerors of Gaul "en si rude, desplaisant et facheux pais" and marvelled at their pertinacity in searching for hot natural waters in which to bathe. The 17th century saw a revival of the reputation of the waters, and in 1788 de Brieude was writing of their value in every kind of asthma. Today Mont-Dore is widely regarded as the *providence des asthmatiques* and the *capitale de l'asthma*.

Besides its altitude and beautiful situation Mont-Dore has its natural waters, employed in many different ways for respiratory disorders. Coming from eight sources at temperatures of 38–44°C, they contain unus quantities of bicarbonates, iron, arsenic, and sil giving off carbon dioxide and nitrogen. Taken mouth they are believed to regulate nutrition metabolism; applied to the mucosa of the upper resp tory tract, they are astringent and *tonefiant*; in m or in dry vapours (aerosols) they are sedative and mote resolution; and in baths and douches they achi various effects. The Mont-Dore doctors, re asthmatic attacks as manifestations of a diathesis, do devote themselves to local treatment of bronchial spa but aim at modifying, during the three weeks' cure, underlying metabolic disorder. One of the me employed to this end is a decongestive douche ap over the liver.



Mont-Dore from the hills.

The thermal establishment—so large that 2500 patie can be treated at one time—strongly resembles a tem in which a spring occupies the place of an altar. the modern side, the patient's faith is bound to strengthened by the ingenuity of the apparatus used f producing the mists, aerosols, douches, and baths wi which he is treated; and by the declaration that " ne soigne au Mont-Dore que les maladies des vo respiratoires, mais on les soigne parfaitement." The can be no doubt of the great benefit often conferred the combination of so many therapeutic factors.

Mont-Dore too, "centre mondain, artistic, et sporti has its casino, and its charming golf-course A funicul takes one to the plateau du Capuchin and a teleferic to t Sancy. The season for the cure is from May 25 to Sept. but the town is also a winter sports centre, with good ski in March and April.

LA BOURBOULE

In a neighbouring valley lies La Bourboule (2765 ft which in sixty years has enlarged from a little haml into a major spa, treating last year 12,000 patients an entertaining 24,000 summer visitors. Its vogue bega with the discovery of arsenic in the waters (0 00705 g per litre), which are hot (60°C) and exceptionall radioactive. They contain bicarbonates and chloride an have been likened to arsenical and radioactive sea-water

The basis of the cure at La Bourboule is drinking the waters in small and carefully regulated quantities they are supposed to promote hæmopoiesis, reduc hypersensitivity of skin and mucous membranes, ar

Aix douche.

which acts as a lubricant for manipulation, and it is in the natural state for douches and baths. For king, water with a low mineral content from two springs is given to promote diuresis.

r the end of the 18th century the Aix douche had me the chief form of treatment. The general he-massage is given out by two attendants:

> It is not a shower-douche, but a double jet-douche: of the jets is discharged from a large supple tube which of the attendants holds placed on his thigh, and manies by slight displacements of the trunk and lower limbs. keep the hands free to massage beneath the douche. patient is seated on a wooden stool; one of the two tors places himself before the patient and the other d him: the douche-massage is carried out in a symral fashion. The dorsal and lumbar massage is next med, the patient lying flat on an inclined plane. The tion is terminated by a general douche without massage the patient undergoes while standing upright in the r of the cabin. The douche massage lasts ten minutes ses up about 220 gallons of water at a temperature to 104 F.
>
> f it is so desired, the douche-massage may be preceded '*bouillon*,' i.e., a stay for some minutes in a narrow where a copious shower of water at 110 F is made to ontinuously: this shower, when it falls, breaks on the d, forms a dense cloud of thermal vapour, converting hamber into a natural hot vapour bath. The douchege has necessarily to be followed by a rest in bed for an or less during which time the patient perspires freely hen reposes (reaction time).
>
> he Aix douche is an operation of considerable versatility; hysician, in fact, can vary at will (1) the temperature water, (2) its pressure, (3) the terminal douche.'[10]

merly, wrote Pidoux in 1866. Aix distinguished by the brutality of its methods of douching, bathing, sweating; but its practice became discriminative. today, as the principal rheumatic spa of France. ers a wide range of treatment, as well as the fruits g experience. All forms of subacute and chronic natism are variously treated, and apart from the effects of manipulation on the joints and muscles—hing of adhesions; absorption of exudates, rates, and fibrositic deposits; alleviation of pain; ration of muscle—there are said to be useful general s on metabolism, the action of the skin, and other y functions. Apparatus in great variety permits opriate exercise of almost any group of muscles ing special treatment—such treatment being given, e necessary, under water. All this equipment would ost of our own orthopædic departments with envy. e staff of the vast and modern bath establishments elected from the same families in the locality, after a etition which takes place after two years of teaching, ding anatomy, hydrotherapy, and manipulations.'[10] training is controlled by the local medical society. the spa has a vigorous medical life, producing many reports in a journal, *Rhumatologie*. Two international conferences have been held at Aix since the war, the first on "social thermalism" (1947)[11] and the second on chronic degenerative rheumatism (1948).[12] Besides rheumatism and gout, the major indications include neuritis, neuralgias, and the disabilities caused by poliomyelitis and injuries.

At Marlioz, near by, a cold sulphur water is used in various ways (mists, aerosols, &c.) for nasal catarrhs and other upper-respiratory disorders.

Besides the natural beauties of Savoy, Aix offers all the usual holiday attractions—ski-running on the lake, fishing, casino, golf, race-course, and an easy ascent by "the most powerful teleferic railway in the world," to Mont Revard (5083 ft.), with its appropriate sports in winter. The new baths establishment is open only from May to October, but the old one is open all the year. Patients generally spend three to four weeks at Aix, followed by some ten days at a neighbouring mountain resort.

EVIAN

Evian is charmingly situated on the south shore of the Lake of Geneva, sheltered by mountains. The altitude ranges from 1220 to 1950 ft., and its summer warmth is tempered by breezes exchanged between the mountains and the lake.

Its waters are cold, hypotonic, and almost free from chlorine, and they offer a "cure by diuresis."[13] Drunk at the source, they stimulate renal secretion more strongly than ordinary water, and they are said to have a dehydrating effect because considerably more is eliminated than the amount ingested.[14] A carefully regulated cure can be of value in renal insufficiency with retention of chlorine and nitrogen; in renal lithiasis and infections of the urinary tract; and also in suitable cases of hypertension and arteriosclerosis. Other conditions in which good results are claimed include gout, cholæmia, biliary infections, and certain gastro-intestinal disorders—the water having a sedative or antispasmodic action on the intestinal tract.

Evian from the air.

The effects of the waters are supplemented by hydrotherapy and other physical methods in an up-to-date

can at best be retarded. The effects of hepatic disorder are so far-reaching that a régime tending to restore normal function can remove apparently remote symptoms; and a great many children—for instance those with cyclical vomiting, dyspepsia, and urticarias—are sent to Vichy: also sufferers from diabetes, gout, obesity, arthritis, and renal disease, and people from abroad whose livers have been damaged by amœbiasis or other tropical diseases. The large establishments make it possible to provide almost any form of physical treatment that may be ordered: for example, there is an astonishing department of mechanotherapy. In the classical *douche de Vichy*, often used in rheumatism, two attendants give general massage to the patient lying under a hot shower, and this is normally followed by a *douche à percussion*. Jets and douches applied locally at different temperatures are designed for various purposes, stimulant and sedative. Lavage of the colon seems to be popular among the clientele, and an ingenious machine, which aims at re-educating a sluggish gut, produces alternation of pressure in the sigmoid colon by rhythmical injection and aspiration of fluid. On the dietetic side, most of the Vichy hotels coöperate by providing patients with one of two special diets, "gastro-hepatic" and "diabetic." For each of these categories there is a list of foods prohibited and foods allowed.

A research laboratory was set up in 1928, working under the control of the Institut d'Hydrologie et de Climatologie of the Collège de France. It has good facilities for work on chemistry and physiology; and in view of the normalising effect of the Vichy cure on disturbances of acid-base equilibrium the investigators there have lately been studying nervous excitability before and after treatment, as measured by chronaxie. Generally, though not always, chronaxie has increased with a change in urinary pH towards alkalosis, and vice-versa.[9] In the careful way that earlier scientific generations ascertained the chemical constitution of the waters, the present investigators are exploring their physicochemical properties. Then comes the harder task of discovering just how these properties affect pathological processes in the body.

The climate of Vichy resembles that of Paris: the season is from April to the end of October, and the spa is fullest when the weather is hottest—in July and August. The civil thermal hospital, founded by Louis XIV in 1696 for indigent people from all parts of France, now has 164 beds and admits about 800 patients between May 15 and Oct. 1.

Covered galleries at Vichy.

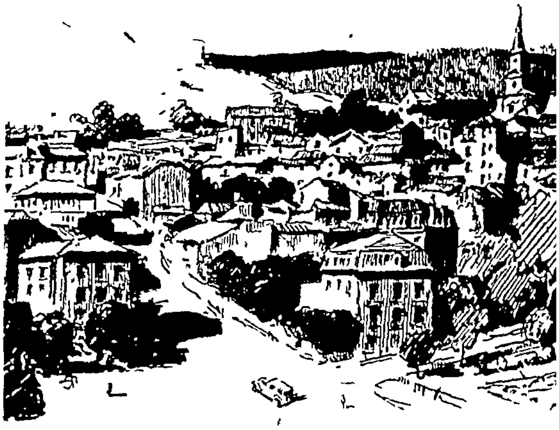
CHATEL-GUYON

About sixty years old, Chatel-Guyon is a rapidly ri spa, which already treats some 15,000 patients a y mainly for gastro-intestinal disorders and colitis. waters, whose consumption is described as the m important part of the cure, are warm (24–38°C) and bes free carbon dioxide and bicarbonates contain an unusu large amount of magnesium chloride (1·85 g. per li Their use is said to stimulate

gastro-intestinal motility, an

is mild. Hence they are re

constipation, whether spasmodic or atonic; for col especially the sequelæ of dysenteries and other trop infections; for digestive troubles in children; hepatic and renal complications of intestinal infect (e.g., "colibacillosis"), and for other miscellane complaints. Methods of treatment practised incl drop-by-drop infusion of fluids per rectum and appl tion of warm mud over the abdomen, which is employed at several other spas. The second-c



Chatel-Guyon.

bathing establishment has this year been enlarg by the addition of some 65 cabins; and the Établis ment des Grands Thermes is now to be complet renovated.

Rigorous régimes are a feature of the medical wo of this spa, and three standard diets are available patients: "Chatel-Guyon is a centre for digesti re-education."

The cure usually lasts 3–6 weeks, and the season is fro May to Oct. 5. Placed at the foot of the Auvergne mounta at 1300 ft., the town has a pleasant climate. There is casino and much to see in the neighbourhood.

AIX-LES-BAINS

Aix is derived from *aquæ*; but the sulphur waters Aix-les-Bains were used medically, it is said, long befo the Romans conquered Gaul and built their lar establishment around the source. In 1600 Henry Navarre, after taking the baths with "pleasure an contentment," decreed that they should be reserved f captains and soldiers wounded in his service. Aix ha a fresh renaissance towards the end of the 18th centur and in 1860 Haute-Savoie was joined to France. The sp acquired and has maintained a great reputatio especially for the treatment of rheumatism.

The clean and pleasant town built around the sourc lies beside the Lac du Bourget (the largest in France) its altitude is only about 900 feet, there is little wind, an the air is mild and dry, but fine mountains rise behin it and across the lake.

About a million gallons of radioactive water, contai ing much calcium sulphate, flows out daily at a tempera ture of 45–46° C; it contains *baregine*, a product o

HOSPITAL APPOINTMENTS

A SCOTTISH REVIEW AND FORECAST

THE ages of consultants and senior hospital medical ficers have been investigated by the Department of ealth for Scotland; and the Department offers a forecast the probable number of vacancies in the next few years. The information was collected in September, 1949; d the Department's report points out that since then ere have been some deaths, retirements, promotions, d new appointments; moreover, some sixty appeals ainst grading are pending. It is believed, however, at "these and other sources of possible error do not riously invalidates" the conclusion to which the figures em to point.

The report deals with 920 doctors, of whom 646 are aded as consultants and 274 as S.H.M.O.s. These, as e report says, are a comparatively young community, d their year-of-birth period covers almost exactly 40 ars (only 2 consultants were born before 1880 and only S.H.M.O.s after 1919). In this 40-year period the age-stribution of consultants and S.H.M.O.s is as follows: and over, 9%; 59–50, 23%; 49–40, 33%; and under , 35%. The age-distribution of the two groups parately, by 5-year periods, is as follows:

Age, years	*Consultants*	*S.H.M.O.s*	*Total*
70 and over	2	..	2
69–65	20	5	25
64–60	52	6	58
59–55	64	20	84
54–50	99	27	126
49–45	127	44	171
44–40	108	26	134
39–35	138	73	211
34–30	36	70	106
29 and under	..	3	3

Vacancies in the specialist service may arise through ath, retirement, or increase in the number of posts. It is not, of course, practicable to assess precisely the portunities which specialists trained in Scotland may d elsewhere in the United Kingdom, in the Services, abroad. With this reservation, the numbers of specia-ts in training at any one time, that is the numbers registrar appointments, should be related to the ospective vacancies."

> "There cannot at present be any certainty as to the number new specialist posts that may be created in the next few ars. The more obvious gaps—in the landward areas and in tain specialities—are being filled now and further expansion the hospital services cannot proceed far in advance of pansion of the hospital and outpatient facilities and in the mbers of nursing and other ancillary staff. These may ove limiting factors. It is safer, therefore, to confine examination for the present to the numbers required to maintain existing specialist establishment."

The normal retiral age is 65, though boards may tend contracts, perhaps with modification, up to the e of 70. Thus specialists born in 1885 or earlier should rmally retire in 1950; and these number 34 (consultants 28, S.H.M.O.s 6). In subsequent years the estimated mbers of "normal" retirals are: 1951, 7 (6 consultants, 1 S.H.M.O.); 1952, 13 (all consultants); 1953, 20 consultants, 3 S.H.M.O.s); 1954, 11 (10 consultants, S.H.M.O.); 1955, 16 (12 consultants, 4 S.H.M.O.s); 56, 16 (13 consultants, 3 S.H.M.O.s). Possibly not all ese retirals would be followed by individual replacements; some "representing posts, on part-time ntracts, with a limited number of sessions, might not. me S.H.M.O.s will, no doubt, be replaced by conltants." In addition there will be about 10 death cancies per annum, though, owing to the age-distribuon, the number may be fewer for the next few years.

"These calculations suggest that an output of trained gistrars of not more than 30 per annum would adeuately fill the prospective vacancies for some years to me over the whole specialist field.

> "The number of registrars in each grade, junior registrar, gistrar, and senior registrar, will, no doubt, be progressively duced so as to select from the initial entrants to the registrar grade only those capable of filling specialist posts. This qualitative selection should presumably be accompanied by a quantitative reduction so that the numbers emerging as trained specialists roughly approximate to the prospective vacancies—in Scotland and elsewhere. The proper rate of reduction at each of the several years of the registrar's training is a matter for consideration. The number of senior registrars in each year of training should presumably be related closely to the annual expectation of specialist vacancies. The number of registrars in each year has to be greater than the number of seniors and the number of junior registrars greater than the number of registrars. For example, one estimate is that for every 30 specialist posts that fall vacant each year the appropriate numbers of registrars in training might be:
>
> | | | |
> |---|---|---|
> | Senior registrars: | (? Fourth year | 30) |
> | | Third year | 30 |
> | | Second year | 30 |
> | | First year | 30 |
> | Registrars: | Second year | 40 |
> | | First year | 60 |
> | Junior registrars | | 90 |
> | *Total no. of registrars* | | *280 (+ ?30)* |
>
> If the process of selection is more severe the numbers in the earlier years might be greater, and conversely."

Taking 30 as the annual number of vacancies in existing posts in Scotland for the next few years, the necessary number of registrars in training to fill these posts is about 300. "Allowance has to be made, of course, for new posts and other needs outside Scotland, but even so, it seems necessary to consider whether the numbers of registrars and others at present in training to be specialists are justified by their prospects of obtaining specialist posts."

The report ends with this warning:

> "It is also necessary to consider the needs of the hospitals for medical staff below the specialist level in order to carry on the essential work. There may prove to be a substantial difference between the number of registrars which the prospect of specialist posts would warrant and the number of doctors of this level of experience who are actually needed in posts the bulk of which have in the past been filled by specialists in training. A situation of this kind might well require some reconsideration of the basis of hospital staffing, the relative responsibilities of specialists and registrars and the scope for hospital posts outside these two categories."

AGE OF GENERAL PRACTITIONERS

The Department has also issued the following figures for the age-distribution of general practitioners of known age in Scotland:

Age, years	*Principals* %	*Assistants* %	*Age, years*	*Principals* %	*Assistants* %
Over 80	0·2	..	40–49	26 0	6·0
70–79	3 6	0·76	30–39	29·6	35·4
60–69	9 2	0·76	20–29	6·7	55·2
50–59	24·6	1·52			

FUTURE REPORTS

Further studies now in progress include an estimate of the distribution, by age-group and locality, of general practitioners; and further tables will show the number of new medical practitioners and medical students who register for the first time in each year in Scotland and England and Wales. Later, all registrar appointments are to be analysed. Finally, the tables will be kept up to date by quarterly returns from the boards showing deaths, retirements, transfers, and new appointments.

The Department remarks that its analysis of specialist posts is still incomplete, but "the preliminary results have appeared so deserving of urgent consideration" that they are published without delay, for the information of regional boards, the universities, and the profession.

An analysis of registrar posts is urgently needed to complete the picture for Scotland; and it may be hoped that the Ministry of Health will soon be in a position to announce the figures for both specialists and registrars in England and Wales. The necessity for providing such information, particularly for specialists in training, has long been apparent; and on this first report from Scotland the trainees may judge that their darkest surmises are confirmed.

thermal establishment; or, when suitable, by bathing and sun baths at the attractive plage. Diet "is given every possible attention by the hotel-keepers."

Though most of the spas described export their waters, those of Vichy (Celestins), and Evian have probably the largest circulation. The subterranean torrent of the Cachat spring at Evian is piped and bottled in immense quantities, supplying some of the benefits of the spa to patients at home. No longer a "live" water, and less stimulating to the kidney, it can be taken more freely. Despite the large flow from this spring, the mineral content of the waters is virtually the same as it was when accurate analysis was first performed some sixty years ago.

The environment of Evian, however, cannot be bottled. It is both a hydromineral and a climatic station, and despite its physical-culture stadium, sports grounds, golf, great hotels, and elaborate casino, it is a restful place. Short journeys by water or by road bring one to others still more beautiful.

The Spa and the Social Revolution

The spas of France, as of other countries, have been developed as resorts for the wealthy. They have their hospitals for the poor, and their establishments for the people of modest means; but their main support in the old days was from the well-to-do, for whom fine hotels were built and every kind of entertainment was provided. Since the war much of the foreign clientele has been excluded by currency restrictions; and though we may hope eventually to see this particular obstacle removed, the continuance of high taxation in most countries makes it unlikely that the health resorts will regain their old fashionable glory.

Adaptation to the post-war social revolution cannot be easy. The temptation for any spa which is already a pleasure resort is to concentrate on its material attractions—its beautiful situation, its amusements, and its luxurious hotels. It can easily transfer its appeal from curists to tourists. Alternatively, however, it can become austere, returning to the old tradition of the place of medical retreat, where all and sundry can find simple accommodation and the best of medical care. Facing this choice, official French policy seems to be a compromise, with the balance rather tilted towards the medical side.

Opening the congress on *Thermalisme Social* at Aix in 1947, the minister of health said:

> "We have too long lost sight of the true character of a thermal cure. . . . A small error of vision has developed: our big stations have become much better known for their casinos than for their curative establishments, for their palaces than for their hospitals. . . . We must frankly review the problem from the right aspect—regarding the thermal towns as a natural resource which we can use for the benefit of people whose suffering we ought to relieve."[15]

The director-general of the Sécurité Sociale was cautious but also definite:

> "A spa is not and should not be preoccupied too much with tourists and holiday-makers. Its purpose is not to provide a tired worker with a holiday on sick-pay: its purpose is to look after him and to treat him. Certainly the importance of the tourist problem should not be underestimated, especially the problem of the tourist with limited means; and the spa, in so far as it is also a holiday resort, may have a part to play here. But the problem of the spa proper is, and must remain, purely medical. Only medical factors can be taken into account when making decisions on these matters. Indeed we might even go further and consider whether tourists who are not taking the cure, or who are not taking it on medical advice, should not be excluded from the spa to make room for those who are in real need of treatment. To put it differently, if in future our spas are to be organised on a democratic basis worthy of the name, logically we ought to give absolute priority over tourists to patients recognised to be in need of a thermal cure."[16]

Speaking of the growing aspiration that everyone should become equal before Medicine, he argued that spa treatment should no longer be the privilege of limited section of the community. The tendency i many countries towards equalisation of incomes dai reduces the number of individuals and families who ca face the expense of a thermal cure, and according arrangements have been made to help them.

> "One of the essential characteristics of thermal trea ment, which distinguishes it from all other forms of therap is that the cost of treatment proper represents only a fracti of all the expenses entailed. The heaviest expenses a often fares and board and lodging. This necessitates putti into operation methods of administration which are n needed to the same extent for other forms of therapy. T social-security organisations have had to enter into agre ment with the hotel-owners at the spas as well as with t doctors. They have had to introduce ways of reimbursi patients with fares. They have been obliged to set up speci administrative machinery."[17]

Very broadly speaking, the French system of soci security allows every patient to recover from the region funds about 80% of the fees paid to his doctor, and t charges for ordinary medicines; and the same princip has been applied to the spas. Patients approved for cure can reclaim their third-class fare, 80% of the co of three weeks' treatment, and 4000–5000 francs (varyi at different spas) for their lodging. The result of the measures is that the spas have revived remarkably sin the war; their pensions and their hostels for childr are well occupied during the season, even if the gre hotels are not; and at some of them there is *beaucoup* *monde* though less of it is the *beau monde* of the old day

Believing strongly in the health resort and the cur France has gone far to ensure that their benefits shall enjoyed by all who need them—according to their sta of health rather than the state of their finances. "F the idea of the patient as an individual dependent on h own resources, social security substitutes the idea of collective guarantee against illness and its cons quences."[18] And the spas have thereby been given new lif

But even in these difficult times the French are n thinking in purely national terms; they have n forgotten that their spas formerly drew health-seeke from half the world, and they believe that if the vario national health services were coordinated this cou usefully happen again.

> "Popular spas have always been visited by families fro many foreign countries. Today we must stress their inte national character—not only for families in easy circumstanc who can afford a journey abroad, which is often very expens but also for the whole of the population whatever the income group. Every country should make a list of t treatments offered at its spas, and where a disease can treated most efficaciously at a foreign spa patients should enabled to visit that spa to take advantage of the faciliti offered there. To begin with, these international exchang will no doubt give rise to difficulties, and will only have limited application. But the principle should be establishe At present we send patients abroad for serious operatio which cannot be carried out in their own countries; in t same way we must arrange for patients to be sent abroad f thermal treatment which offers them their only chance cure or relief. Though at present these patients may be fe there will probably be more and more of them in the future."

In the discussions between the governments of Weste Union the possibilities of such arrangements have alread been canvassed.

Meanwhile many thousands of English people hav been experiencing the refreshment of spirit that com of visiting their nearest neighbours abroad. More an more of us have come to feel the truth of the saying th everyone has two countries—his own and France. An whatever our opinions on spa treatment, more and mo of us have found reason to believe in the corrective an therapeutic effect of a visit to our second country.

15. *Op. cit.* (ref. 11) p.8.
16. *Ibid*, p. 13.
17. *Ibid*, p. 15.
18. *Ibid*, p. 120.
19. *Ibid*, p. 16.

e phisitians are covetous, ignorant, impudent & runken, & for by that means he ruines himself and his rofession.

The universities have a great share in all these ill ayes by theire first bringing up & binding their yong udents. For they have lost the old & sound Aristoteles arning & spend all their time in ye new fangled fopperies [Cartes, Gassendi, Boyle, Hobbes, [? Regius] &c.

If ye phisitian dine abroad, misse his houres usualle orning, noones, & nights, or rather all the whole day ith slavish attendance, he then certainly looses his patient at brings ye [? aches] & becoms reproached [thereby]: sent for, & comes not presently, another comes & he neglected ever after of ye family & all their relations ith scandall of neglect. If ye phisitian venture his life pon attendance on his owne acquaintance in the dredfull me of ye plage, in the conclusion they rewarde him, with ying, he did his duity, as they served me in this Citty f London, where I got nothing soe much as the fugitive hisitians, but the King's gratious thanks for attending is soldiers in St. Thomas' Hospitall all ye time 1665.

The phisitian old & crasy shall be called out of his bedd London in winter nights to visit his patient & wth. mall reward, but in sum̄er or winter, when that patient omes to London & is sick he shall undeservedly call nother phisitian to his attendance & neglect the former t. attended in ye winter nights in ye country.

Then I considered in yt. letter how ye Divinity had n it far greater hopes & opportunities of preferment a better settled way of perpetuity & continuance of upportance for yonger Students by being Chaplains. icears, Curates, through all England, to wch. they did uickly attaine, but phisick was a tedious, long, & hargeable study, & 10 or 12 yeares at least after all ime & charge of taking a Dr. of Phisick's degree, before ny Dr. could hope to live by the benefitt of his profession. I then alsoe consider the com̄on and civill lawes. rch. farr exceede physick in certainty both of honour nd riches, to the carefull & industrious Students of them.

Mr. Church Dat: 2.72. to my last letter returned yt. e still continued his intentions for yr. son for phisick thereby to endeavour his maintenance by country ractice. I returned answer by letter dat: Novb. 2. 672 that what I had writt last to him was absolutely rom my [? sence] of ye finall decay of ye profession of hisick: but he continued soe still resolved. I would fford yr. son ye best entertainmt. I then could for dyet lodging for 3 or 4 months, that he might have opportunity in London to see our constant practice in our Hospitalls, both of phisick & surgery, & to be acquainted ith ye Apothecares [? books] & medicines, their gardens f phisicall plenty, & wth. the most materiall books for ractise of both. But now the improvement must wholly rise from himselfe, as he finds occasion by his owne ractise, & thereupon carefully reading & extracting constantly & exactly noting for his private use & emory what he shall read upon every disease, & thereby earne a readines to comprehende & put any case to any lder phisitians to obtaine his counsell & experience upon e care of his case.

Now this practise if industriously followed will really ring him into the right way & method of the practise f the art of phisick. And this way I was. And this ay of study & improvement of himselfe, by his owne dustry. I am now informing, suggesting & insinuating pon yre. son's capacity. For after he fully understands this course of study & practize mentioned, he must apply himself into ye country & im̄ediately put himselfe into dayly practice & exercise & curing poore patients. For reading alone, is good for just nothing, wth.out the constant association of practise & bringing all he reades to the use & profitt of the sicke by his owne contrivement, judgement, industry, & constant diligence, ever altering framing & suiting his medicins proper to the present case. Soe practise without constant Study, reading & examining what hath been done on like occasions by able renowned & famous old practizers of phisick wil be successles [;] but both judiciously joined together may produce an happy practice both to ye phisitian & patients, by God's constant blessing thereupon, wch. shal be hartily desired by

Yre. reall friend & servant

TH: WHARTON.

Points of View

ARMY MEDICINE IN THE LATE WAR

SOME MISTAKES OF POLICY ?

JOHN W. TODD
M.D. Lond., M.R.C.P.
ASSISTANT PHYSICIAN TO FARNHAM HOSPITAL; LATE LIEUT.-COLONEL, R.A.M.C., OFFICER IN CHARGE OF MEDICAL DIVISION

(Continued from p. 1148)

3. Abuse of Hospitalisation *

THE reasons for admitting a soldier to hospital are: (1) he is acutely ill, bodily or psychologically; (2) he has chronic complaints and needs investigating; or (3) he has chronic complaints and it is necessary to dispose of him. There is, of course, some overlapping between groups; but most cases fall clearly into one or other.

Soldiers in the second and third groups were commonly given treatment; but, leaving aside those with such chronic "surgical" lesions as herniæ, which could be radically cured by surgery, they were not, or should not have been, admitted for the main idea of having treatment, unless they were also to be invalided from the Army. Treatment given for chronic "medical" conditions is virtually never really curative: and such remedies as insulin, liver extract, and thyroid, which when given continuously are almost as valuable as cures, had little relevance to the Army, since those affected by the diseases they relieve were almost all invalided. Even treatment for such a common recurrent condition as peptic ulcer was only very rarely followed by a man's returning to duty: in the case of soldiers a regulation expressly made invaliding compulsory, and among officers very few were retained in the Service after they had been proved to have peptic ulcer, unless perhaps they were Regulars.

THE ACUTELY SICK

Apart from malaria, and in certain situations venereal diseases, there were few regulations which implicitly or directly made hospitalisation compulsory for those affected by some specific acute disorder. It was assumed by the authorities, just as it is assumed in civil life, that the regimental M.O. or other doctor who first saw the patient should use his discretion as to whether to deal with him on the spot or evacuate him. It is therefore difficult to estimate how far acutely sick soldiers were unnecessarily hospitalised. Doubtless a high proportion of the wounded and the acute psychiatric casualties in battle were rightly taken to hospital. But it was my impression that too many of those with acute trivial illnesses were admitted. Regimental M.O.s and others in similar situations were rarely if ever *encouraged* to treat their own sick until they had recovered. Directives, suggestions, and propaganda tended to encourage the opposite attitude. And, whereas one sometimes heard of a regimental M.O. getting into trouble from his A.D.M.S. for retaining the sick too long, one did not hear of him being praised for looking after his own men in preference to sending them to hospital.

But certain regulations, besides those concerning malaria and amœbiasis, urged or compelled medical officers to retain men in hospital with certain acute conditions for fixed minimum periods. For example, an ALFSEA order said that soldiers who had had appendicectomies *must* remain off duty for at least a month. This order did not differentiate between the various categories of soldiers. It followed, therefore, that a clerk

---

* The word "hospital" is here used as a generic name for all Army medical units behind the regimental aid-post.

THE KING'S FUND

STAFF COLLEGE FOR HOSPITAL ADMINISTRATORS

PRESIDING at a meeting of King Edward's Hospital Fund for London on Dec. 14, H.R.H. the Duke of GLOUCESTER said that the main purpose of the meeting was not, as formerly, to approve the list of grants for the year; it was rather to look forward and to take stock of the Fund's commitments. The management committee asked approval of three main groups of activities. First, they proposed that £100,000 be again placed at the disposal of the distribution committee for grants to hospitals. (Last June £250,000 was allocated for homes for aged sick associated with the hospitals, and this scheme was making good progress, but a full report would be deferred until the next meeting.) Secondly, they asked for £80,000 for the convalescent homes committee: "a new spirit is abroad among the convalescent homes which is largely due to the encouragement we have been able to give to many little homes which had become somewhat isolated." Thirdly, there were various miscellaneous activities and projects, including some which were well rooted before the recent changes (e.g., nursing recruitment and the emergency Bed Service), and other newer ones, such as the division of hospital facilities, the staff college for ward sisters, the training school for medical records officers at the Middlesex Hospital, and the projected training centre for hospital caterers at St. Pancras Hospital. The most important new departure was the establishment of a staff college for hospital administrators.

"Today, as a result of the new Act merging two separate administrative traditions and adding something of its own, there is evidence of a widespread need for practical help, and many believe that hospital administration, as understood in this country, is at the crossroads. Nobody, the Minister least of all, wants a bureaucratic hospital service; and if that is to be avoided, an active policy must be pursued aiming at flexibility and initiative. We believe that the foundation of a residential staff college where the different interests can come together may prove a decisive event. We want the hospital administrators of tomorrow *not only to be efficient but to work out for themselves how* to let the humanity which is the essence of the hospital shine through and illumine the administrative detail. We are therefore taking counsel with others interested, and notably with the Institute of Hospital Administrators, as to how best to achieve this result. We have acquired premises; we have appointed a small committee of which the Rt. Hon. Malcolm McCorquodale, M.P., is acting as chairman, and the members of which will be Sir Wilson Jameson, Mr. Fred Messer, M.P., Captain Brierley of the London Hospital, and Mr. Lees Read of Guy's Hospital, who is the president for the time being of the Institute of Hospital Administrators. We have been fortunate in persuading Mr. Constable, the present house-governor of St. George's Hospital, to resign his hospital appointment and become the first head of the new college. Some months must yet elapse before the college can be opened, but we anticipate that when we meet here in the summer it will be possible to name a definite date."

Sir WILSON JAMESON, chief medical officer of the Ministry of Health, said:

"The hospital part of the National Health Service is administered *in typical British fashion by committees*—committees of men and women who, at no small cost to themselves, give generously of their time to voluntary service. But a large modern hospital—still less a group of hospitals—cannot depend for its day-to-day management upon a committee however willing and competent its members may be. Just as a business must have a managing director so must a hospital have a chief administrator —and hospitals now constitute one of the largest, most complicated and costly enterprises in this country.

"In the Metropolitan regions there are more than 120 hospital management committees, each with a chief administrative officer; and there are in addition several hundred senior officers in charge of unit hospitals. Though hospital management calls for *special* inborn qualities of mind and spirit, much can be done to develop and strengthen these qualities by an enlightened *system of training*. In some countries training in hospital administration is provided by universities, but in England such provision on any scale is most unlikely, though in the teaching of the subject some of the methods of university instruction might well be u So here is a real need that the Fund can meet. The prop is to provide a college of hospital administration—in residential for students, in part a centre for the excha of ideas between existing administrators, members boards and management committees, doctors, nurses, others connected with hospital work. Wisely conduc such an institution will do much to raise the standard hospital administration in this country."

Sir EDWARD PEACOCK, treasurer, reported that Fund's total estimated income was £644,000, of wh £253,000 was ordinary revenue (mainly from inve ments) and the balance from the Nuffield Trust for Special Areas, and from legacies. The estimated exp diture for the year had been increased by the spec allocation of £250,000 for homes for the aged sick. T involved the spending of all but £47,000 of the yea receipts, an unusual procedure which it was not propos to follow in subsequent years as it was customary transfer large legacies to reserve. Sir ERNEST POOL chairman of the management committee, present estimates for the year.

THE PROFESSION IN DECAY

A WARNING TO ENTRANTS

A letter from THOMAS WHARTON, F.R.C.P., *to* Mrs. CHURC *dated May* 15, 1673.*

To yre. desired answer . . .—I shall returne you direct *the same I did to Mr. Chancēler Burnell to* his lett dated Nov. 4, 1672, wherein he desired my care a directions in the placing yre. son James, yt. [that] might have an insight of both chirurgery and anatom

. . . I writt to this purpose, that at present I had a yon student with me, yt. had bene 6 or 7 yeares at Oxfor of very good parts and naturall abilities, & graduat & had taught my son these 3 yeares, now *fitt for* university, that this yonge student had acquired exce lently in phisick, anatomy, surgery, botany, &c: y for all that I designed to disuade him from the embraci phisick for his livelihood; because now there was mo *apparent cause of its ruine & destruction* than ever; b the swarmes of quackes, mountebācks, chymists, Apoth cares, surgions, & especially this new upturned *brood* Vertuosis, who are most likely by their Jesuitisme policy, English-books, experiments, & receipts in phisick to fill all the familes of Note in England with their stuf to overthrow all our old settled & approved practice phisick *especially in London*: which is now miserabl impoverished by its burning & building & desertion trade, that they have scarce money for theire presen subsistance, little for phisick & phisitians & like to hav less hereafter. Soe that every one out of necessity *an* good husbandry must become theire owne phisitians make theire owne phisicke. For all our ladies & gentle women kepe & *store up receipt* books & closetts medicins fitted for most occasions.

Besides, *Phisick* is too much overstocked with Student graduated from ye University. For I do realy believe i will easily appear that now there is in *England 400* fo one phisitian that was formerly: for yt. it is impossibl but yt. theire owne multitude must shortly ruine *the* profession, without the plotts and envy of theire enemies.

He yt. begins ye practice of phisick, must resolve to be a perpetuall slave & servant *to ye meanest* & basest, all the dayes of his life, & if [he] neglect one instant, & comitt one error, or speake ye leaste word *amisse*, his fame & name is lost for ever to him & if his patient dye, hath killed him for certain, by ye view of ye *people*. *Upon ye Phisitian* is imposed taxes, poles, great charges for houses & servants & entertainments, more in this *age* than ever formerly! *Coaches*, [? Jacks] & charges expected, feastings. He is never called to any but miserable patients, where the *Apothecary, or* Surgeon or Chymist have bene tampering soe yt. cōmonly the phisitian is brought onely to take away *the scandall* of killing him to himself. The phisitian is made that cōm on jeare of the hunt, neglected *cōtemned & reproached* upon all *occasions : and* wch. is worst they will one reproach & scandalize another for his ill practize: wch. is very certaine & evident *to all* practizers. For generally were clearly there. not for their health's sake. because their units wished to be rid of them. were affected by organic defects. such as chronic bitis. splenomegaly, or flat-feet, but the reason for uselessness as soldiers was nearly always to be sought their psychological state. We were not allowed to them out. and all we could do was to recommend r discharge from the Army and keep them until a pital train took them to Secunderabad. which at time was their next port of call.

---

* *Reproduced by permission from a MS. letter book in the library of the Royal College of Physicians of London.*

When a soldier finally received his medical board in ntral India, if merely lowered in category. he was harged from hospital and sent to the base reinforcent depot at Deolali. whence he would later be posted a unit considered suitable for him. But a British dier, recommended for invaliding to the United ngdom, was transferred to a hospital at Poona. ere he later had a review board. Only on confirmation the previous board's decision could he be sent to a by transit camp, to await the arrival of a ship to e him home.

Here, then, is the extreme example of the abuse of pitalisation in the Army. The damage done to rale by retaining men with chronic complaints in spital for such long periods is incalculable: and if eir military value at the beginning of their long rney was small it was much less at the end. The in reason for this state of affairs was that the disposal soldiers was made a *medical* matter. Besides the dical evacuation machine for the acutely sick and nded, there should have been a second machine for ting rid of soldiers found unsatisfactory.

ADDITIONAL REASONS FOR PROLONGING HOSPITALISATION

In civil life the great majority of hospital patients ve a strong desire to be discharged as soon as possible. is not so in the forward units of a war-time army. e military hospital's patients may come from condins of great danger and discomfort in the Burma jungle, which their discharge from hospital means a return. d however long a soldier remains in hospital he does t lose money. Even the best type of soldier, therefore, uld seldom strive to get himself discharged. The dical officer, too, when contemplating discharging diers to duty. might easily be influenced by the cking conditions to which they were returning.

There were also some less creditable reasons for longing the stay in hospital. One was the practice employing patients there. Such men were not as a e fighting soldiers but technicians or followers. In rma, sweepers, who were always scarce, were perhaps st apt to be retained and employed in this manner, en for months at a time. Other categories who were ilarly treated were cooks, clerks, and soldiers with skilled trade such as painting. metal-working, or pentry. For example. while I was stationed in a pital in Bengal early in 1945. a Madrassi came to office and asked to be discharged; he had been mitted three months previously and had spent almost whole time cooking in the sisters' mess. The reason his request was that his friend. who had been cooking the officers' mess for a similar period. had just been charged.

FATE OF THE SOLDIER AFTER DISCHARGE FROM HOSPITAL

In England or in base areas abroad the soldier who s admitted to hospital usually travelled only a short tance. And on discharge he immediately returned his own unit (unless the "Y list" procedure was in eration, when, if in hospital for longer than a specified riod, he returned to his depot to await posting). In rma, however, the soldier who was evacuated beyond field-ambulance level—and only the most trivial cases were not so evacuated—often travelled a long way to a casualty clearing station or malaria forward treatment unit, frequently by air. Even if he was retained in one of these units for only a few days. he might on discharge be some hundreds of miles from his own unit, especially during the mobile phases of the campaign. His usual destination was then the nearest transit camp, where he waited for an aeroplane or truck to take him forward. I have been unable to discover any statistics relating to the average time between discharge from a forward medical unit and the arrival back at the Front. Presumably this figure varied enormously according to local circumstances and in different periods of the campaign. At times it was a matter of weeks or months.

Soldiers who were evacuated as far as the advanced base hospitals of ALFSEA or the base hospitals of India Command were, on discharge, commonly sent to a convalescent depot. For a time there was an order in Central Command in India insisting that *every* soldier originating from ALFSEA should be so disposed of. For a front-line infantryman who had been severely wounded or had had such a febrile illness as typhus fever this was no doubt desirable. But it seemed absurd that clerks. drivers. sweepers, and nursing orderlies should go to convalescent depots and there indulge in activities far more strenuous than those performed when on duty. Here is an example of the common Army error of assuming (in orders) that all soldiers are equivalent. The lives led by parachutists and Pay Corps clerks. by commandos and sweepers in base depots, or by infantry of the line and medical officers in hospitals differ so widely that few orders can suitably apply to them all.

There seem to be no statistics as to the average time spent in convalescent depots in India and Burma. But it appeared that in many depots this time was very long. One commonly heard of men kept there for weeks after quite trivial illnesses.

Men originating in ALFSEA, when finally discharged to duty in India Command, were ordered to be sent to their depots. When I was at a hospital near Madras in 1944 many of our patients had to go to the Punjab. in which their depots lay. To get them on to a train might take a week or more, and about another week would be spent on the journey. However short a time they were kept in their depots, there was inevitably a long period before they finally arrived back in a forward unit. And at that time a high proportion of our patients had not been seriously ill, many only having had malaria.

British soldiers who had been recommended evacuation to England, and had finally had their review medical boards in a hospital at Poona, waited at a transit camp for a ship. But this ship might be many months in arriving, apparently because of the refusal of sea-captains to accept as passengers men who were nominally invalids. When the voyage was over the men would have their final board; and, according to whether invaliding or recategorisation was decided on, would return to civil life or to their homes or depots to await a posting.

The total period between a soldier's evacuation from the Front by his regimental M.O. and his final board in England was often very long.

I once saw a corporal who had spent two whole years in the process, starting in the Western Desert of Egypt and moving slowly via Durban. where he spent a year. As his disorder was congenital cystic disease of the lung, he could hardly be helped by being in hospital.

On another occasion I saw a warrant officer class I who was awaiting a posting in his depot and had already been 13 months off duty. He was a chronic bronchitic who, because of a small hæmoptysis, had been originally admitted in a base depot who had had an interval appendicectomy—and, in accordance with modern teaching, was out of bed the day afterwards and taking vigorous exercise within a week—was not allowed, for a whole month, to return to his duties of sitting in a chair. ALFSEA regulations concerning infective hepatitis, if not actually fixing minimum periods in hospital, gave the impression that even the mildest cases should remain casualties for many weeks.

Quite apart from these actual regulations, there seemed to be a widespread tendency to retain men with acute illnesses too long in hospital. And in my experience the C.O. of a hospital or the A.D.M.S. or D.D.M.S. very seldom made serious attempts to prevent this happening. There might be trouble, on the other hand, if someone in authority concluded that a single soldier had been discharged from hospital too soon. A long ALFSEA order issued to all medical units told the story of a Gurkha soldier with an eye affection who had been sent back to his unit without proper treatment. The responsible medical officer's behaviour was strongly condemned, the evident reason for the circulation of the order being to discourage others from committing a similar offence. But thousands of soldiers could be kept in hospital too long without causing anyone to receive the mildest reproof.

ADMISSION FOR INVESTIGATION

Elsewhere I have advanced the opinion that, in general, admission to hospital as a means of investigation is a mistake, both because of its futility and because of its tendency to worsen anxiety and encourage invalidism (Todd 1949). Others have put forward a similar view. Conybeare (1943), in reference to Service patients says:

> "Most psychiatric conditions present symptoms of a physical kind. Only too often are such patients referred to hospital where the most searching investigations—X rays, test meals, blood examinations, chemical and metabolic investigations, electrocardiograms, even gastroscopy—are carried out in a ruthless determination to exclude any possibility of physical disease. Such a régime carried out in hospital, often over many days or even weeks, only too often permanently shakes the confidence of the patient. Nor does this criticism only hold good with psychiatric conditions. It applies equally to personnel referred unnecessarily to hospital for the so-called investigation of a cardiac murmur, albuminuria, dyspepsia and other conditions. . . . Almost all necessary investigations can be carried out adequately in an out-patient department and the hospitalisation of personnel where hospital treatment is not essential can do nothing but harm."

Yet in the late war vast numbers of chronically complaining soldiers were hospitalised for investigation. Perhaps the largest category, at least among troops stationed in England, were those with the predominant complaint of dyspepsia. In some military hospitals, and especially in the Service wards of E.M.S. hospitals, might be seen rows and rows of dyspeptic soldiers. The essential basis of the symptoms of the majority was clearly to be sought in their state of mind—typically they complained of being unable to stomach the "greasy" Army food. Other large categories were those with the cardiac symptoms of emotional origin being investigated to "exclude" organic heart-disease, the chronic bronchitics, (especially if they had brought up a faint trace of blood, when they might have bronchoscopy and bronchography performed), those alleged to have had fits, and the enuretics.

This superfluous hospitalisation could rarely be blamed wholly on the official regulations, as in the case of malaria. Nevertheless, many regulations, by urging investigations in special circumstances or by insisting that those with certain complaints should be referred to a specialist, encouraged hospitalisation, and few had the opposite tendency. Many of the boarding regulations had a similar effect. For example, it was laid d that those with bronchiectasis should be invali Medical boards, therefore, often insisted on a bronchog in suspect bronchiectasis cases; and there is a com belief that bronchography should be done only inpatients.

What I have said so far applies mainly to tro stationed in England or in base areas abroad. In forward areas, by reason of distance, soldiers co hardly be sent as ordinary outpatients to a milit hospital, and it may be doubted whether the regimen M.O. often wished to send them. If a soldier's sympto did not seem severe and he was a useful member of unit, any investigation could be postponed until unit was withdrawn from the fighting line. On other hand, if he attended the sick-parade so much to be a nuisance, or if in other ways he was unsatisfact as a soldier, the regimental M.O.—either on his o initiative or at the suggestion or urging of a combat officer—would probably evacuate him through medi channels so as to be rid of him. In the forward are therefore, the reasons for hospitalising a soldier we first, because he was acutely ill, and, second, becau he had chronic complaints and it was necessary to disp of him.

ADMISSION FOR DISPOSAL

In England there was no need to admit soldiers f the purposes of disposal. Indeed, the machinery f recategorising or invaliding them from the Army, wha ever may be thought of its theoretical basis, w remarkably quick and efficient. A regimental M.O. cou send a soldier to see a specialist as an outpatient o day, and if the specialist recommended discharge fro the Service the soldier could attend a medical board day or two later, and with the board's confirmation provided with a civilian suit and a railway ticket his home the following day. On the other hand, if th specialist merely recommended lowering in categor and this was confirmed by the board, he could retur to his old unit and continue with his duties until poste to another unit of a type thought appropriate fo him.

Even abroad, in base areas the mere recategorisatio of a soldier did not necessitate his admission to hospital and this could be effected in much the same way as i England. But in the forward areas the situation differed There, if a man committed some serious crime he migh be got rid of through non-medical channels. Otherwis it seemed virtually impossible to dispose of a soldie except as a casualty. Requests to higher authorit that he be posted usually fell on deaf ears, and the fact of his being useless was no official ground fo getting rid of him.

In the Burma campaign medical boarding was forbidden even in such base areas as Chittagong and Comilla, which were hundreds or thousands of miles from the fighting, and could only be carried out back in India proper. And when a soldier reached a hospital in, say, Comilla, he might already have been in the evacuation machine for several weeks. He would there wait for an ambulance train to take him to Calcutta or further. Since there was an order that ambulance trains had to be full, so as not to "waste" transport, he might wait a few more weeks until a train-load of men had accumulated.

The further one was from the fighting, the higher was the proportion of men in hospitals who were there for disposal. In 1944 I was stationed with a large hospital near Madras, whose main source of patients was the Arakan Front, whence they travelled first to Chittagong and then by hospital ship. The surgical division was largely filled with the wounded, but the medical division was often a very depressing place. Ward after ward might be nearly full of useless riff-raff ned: the stoves were useless. Together, my her-in-law and I can just move each of them: so. much sweat we got them into the kitchen passage. e they took a couple of feet off the fairway—until Sunday.

From time to time we've tried to find a scrap-iron ant to take them away, and a fortnight ago I ght I had succeeded. Our local rag-and-bone shop sed to get a man to call with a barrow. I advised men, but the rag-and-bone lady thought one could ge. A week went by and nothing happened, and could stand the sight of the beastly things no longer. ery reluctantly my brother-in-law was persuaded to me in getting them into the back garden. We tried iding them, but they wouldn't slide. We tried rollers nder them but they wouldn't roll. So we heaved and hoved and lifted. The first one wasn't too bad. But the econd was a devil. We got it about four yards of the way hen I collapsed. My entire erectores spinæ seemed to ave divided. I was locked in agony in an anthropoid osition. My brother-in-law, who is a lawyer, offered anipulation, which I refused. After half-an-hour's rest, ke a fool, I returned to the fray. This time it went good nd proper, and I am now resting my prolapsed disc nd blessing the day those stoves arrived. . . .

This afternoon Jeremy rushed upstairs in high delight. Daddy," he said, "the man's been for the stoves." How did he move them?" I asked. "Oh! he just icked each one up and put it on his little hand-cart." eeing my face, he added: "he was much bigger than ou, at least seven or eight feet tall; and he told me that hen all the rag-and-bone men had a competition to e how much they could carry on their little carts, he on with fourteen and a half tons."

Last week I went to the Swedish church in London to e the Lucia. Every town, village, and office in Sweden hooses its prettiest girl for its Santa Lucia on Dec. 13. he wears a crown of spruce leaves bearing lighted candles nd walks in procession with her maids of honour, who fterwards bring round the coffee which is drunk with e traditional Lucia food. Santa Lucia symbolises the turn of the light. Nowadays Lucia's candles are electric, hough I cannot imagine where she keeps the battery. nd I thought it was further symbolic of the infiltration our all-demanding modern way of life even into the dest customs that, at the charming ceremony in ondon, poor Lucia had to make her procession a second me, not now in the dark, as Lucias always have done, ut with arc lights blazing and movie cameras burring, nd there was a microphone recording the Lucia songs.

* * *

Here is an extract from a letter written by Mr. Lamuell radley, surgeon at Dunster, Somerset, on Dec. 16, 38. Until I read it at the British Museum I did not alise how dangerous a Christmas goose can be.

A woman, aged 32, "of good Complexion, handsome statue d healthy Constitution," a year previously plucked five ese; they had been killed by a mad dog, and it seemed ity to waste them, particularly at Christmas time. "The next mation she was seized with a Horror, a trembling, and a eat anxiety of Spirits, which wore off and returned accordg to the state of the moon." The patient thought she as suffering from "the effect of the Poyson which the og had transmitted to these Birds," so she went to "a llow in the Neighbourhood, famous for Curing Mad Cattle: accordingly furnished her with his Drench of which she ok two Quarts at divers doeses: the symptoms of the adness then appeared no more, but sometime after she was iz'd with violent excruciating Pains in her Limbs, which blig'd her to keep to her Bed."

When seen ("As I visited a Patient hard by, I was sent for give my opinion on this Woman"), the bones in one leg, oth thighs, and one arm were found to be "entirely divided the middle." The sternum and ribs were strongly conracted, and the woman's standing height was reduced by ft. She died about 10 months after the plucking of the ese. Autopsy revealed that "the substance of the Bone as reduc'd to the form like to the yolk of an Egg: and what ttle was left was as thin as the Horn of a Lantern, and erfectly flexible."

With some relief I turned to the next MS in the llection—an "Ode to the Right Honourable the Earl Oxford." We are not having goose this Christmas.

Letters to the Editor

CONTROL OF TUBERCULOSIS

SIR,—May I comment on the letter by Dr. Mashiter and others in your issue of Dec. 10?

The control of tuberculosis might have been advanced had the signatories paid a visit to any clinic, in their own region, from which domiciliary management is being undertaken. They would have been able to study the reasons for such a development, the types of cases treated, and the technique employed. They might have discussed with medical, nursing, and welfare staff, and with patients, the psychological and other advantages which accrue from prolonged bed rest at home in contrast to periods in sanatoria where treatment has become such "an intensive process." Finally, they might have furthered the association of sanatorium with domiciliary supervision, thus promoting more efficient use of available beds. Appeals for such coöperation have been made frequently during the last few years but have met with little or no response.

The letter would have carried some conviction if any evidence had been produced that the intensive processes of modern sanatoria had contributed aught towards solving the problem of tuberculosis. Statistical evidence in this country has so far failed to substantiate such a claim. Had the writers reviewed Professor Heaf's first presidential address to the British Tuberculosis Association, they would have recalled his warning that far too much time is spent in the application of intensive processes to unsuitable cases. This has contributed largely to the present breakdown in tuberculosis administration, and has led to delays of nine months or more in the admission of treatable cases.

Domiciliary supervision and management, accompanied by frequent home-visiting, give to all clinic staff a much closer insight into the economic and social aspects of the disease. The value of welfare work is enhanced, and closer relations with the family lead to an increase in contact examinations. (In Willesden, contact examinations have doubled in the last three years.) There can be no more effective preventive measure than the conversion of infectivity. This can be rapidly secured in many cases by immediate rest under proper control and supervision in the patient's own home.

The devastations of two world wars have depleted the British community of industrial man-power. Tuberculosis is claiming a toll from our industrial population (in the age-group 15–50 years) far greater than that caused by any other disease. It is appalling that sufferers from this disease should be precluded from admission to all but a few hospitals and should be forced to wait many months for the institution of treatment. Such neglect leads but to further cases of disease.

In your issue of Dec. 10 Dr. Brailsford suggests that it is unjustifiable to admit, knowingly, patients with open tuberculosis to a general hospital. May I repeat that experience at the Central Middlesex Hospital completely refutes this view? Tuberculous patients are nursed in special wards to which are transferred *immediately* any open cases discovered in the general wards. Such a policy has resulted in an incidence of infection, as evinced by Mantoux-conversion in nurses, *considerably less* than in the better of the two groups reported by the Prophit Survey. A similar administration and lowered incidence of infection was reported by Dr. Court in your issue of Nov. 12.

Effort must be concentrated on increased coöperation with general practitioners in a search for cases in an early stage of disease. The admission of such patients to general hospitals for treatment in special wards can no longer be denied on the grounds of danger to nursing staff. The present position is so chaotic that instant to hospital in Malta, whence he was transferred to Egypt and later to Durban. According to his documents there was never any evidence of tuberculosis.

DISCUSSION

If most cases of malaria had been treated in their own units, instead of being held in hospital for 2 or 3 weeks; if amœbiasis had been diagnosed clinically and its victims had been kept in hospital as a routine for some 2 weeks, instead of 8 or more; if the time spent in hospital by soldiers with other acute diseases had been much less; and if admission for investigation and disposal had not occurred—then the number of beds needed to serve the Burma theatre would have been greatly reduced. And because of the lessened pressure on the evacuation and reinforcement machinery those who were admitted to hospital would not have travelled nearly so far, and those returning to duty would not have stayed so long in transit camps. If in addition convalescent depots had been reserved for front-line infantry and others living similarly active lives, and if the stay there had been considerably cut down, the number of soldiers hors-de-combat for medical reasons could have been enormously reduced, possibly to a tenth, or at most a fifth, of the actual figure.

Although so huge a number of soldiers were unnecessarily hors-de-combat as the result of sickness, this actual *figure* was not in itself particularly serious. For by the very nature of war only a small proportion of the fighting soldiers of an army are, at any one time, actually engaged with the enemy. Many may be in units in reserve, refitting, or retraining; others may be on leave, awaiting posting, or travelling from one theatre to another. The real gravity of the situation is to be found in the *disorganisation of units.* In reference to the Burma campaign, Marriott (1945) says:

> "The effect of disease in wasting man-power is not to be measured merely by arithmetical calculation of man-days lost—gigantic as has been this total. There must also be reckoned the effects due to disruption of units and the influence on morale. In the Arakan campaign in 1943 some units were losing their entire personnel, with replacement by reinforcements, every six to eight weeks. Imagine the task of commanders trying to operate forces, in the face of the already fearful difficulties of climate, terrain, and supply, with all their officers, N.C.O.s, and men constantly changing."

It was not, indeed, surprising that the campaigns of 1943 and 1944 in Burma were so unsuccessful.

I suggest that during a campaign all units should be encouraged, if local circumstances allow, to retain those of their acute sick who look likely to recover soon. As a corollary, the position of regimental M.O. should be considered one of the most important in the R.A.M.C., and confined to sound doctors of good personality. Even soldiers affected by certain mildly disabling disorders which are incurable while they remain on duty but curable in hospital (e.g., jungle sores and some other skin conditions, otitis externa, and many minor surgical lesions) may properly be retained with their units until these are withdrawn from the fighting line. Useless men whose presence adversely affects morale and endangers the lives of others should be disposed of through non-medical channels. Even if their units do not receive reinforcements to replace them, their disappearance will be a gain.

In Burma, in so far as the evacuation of sick and wounded was necessary, far greater efforts should have been made to prevent it from proceeding beyond field-ambulance level. Those brilliant and ingenious feats of air evacuation to base hospitals, which received so much publicity and appealed so strongly to the public mind, should, in general, have been reserved for the severely wounded and those with grave diseases such as typhus fever.

(*To be concluded*)

In England Now

A Running Commentary by Peripatetic Correspondents

A LITTLE while ago, on the spur of the moment, I exchanged our comfortable family saloon car for an ancien sports tourer. So far as cars are concerned I am abou the same mental age as my small son aged five, and together we agreed that the new old car was much more "sporty" than the old old car. Since then the daily trip from our small country cottage into the university town, where he and my daughter attend school and I work at the hospital, has become altogether more adventurous. I will pass swiftly over the early days when the moribund batteries made starting difficult and my unfortunate wife was dragged out to help push the car as fast as possible down a gentle slope to make the engine fire; the discovery that the reason for the stiff and erratic steering was three broken leaves in the near front spring, including the main leaf, which was attempting to perform its proper function in defiance of natural laws; and the unpleasantness of the first heavy rain when gouts of water poured on us through the threadbare canvas roof. The sequel to these disturbing but relatively trivial events was more alarming.

Starting off late (as usual) for school one day, I shot along our country road as fast as the cold engine would gather speed, but we had gone only a mile when disaster overtook us. The road there takes a gentle right-hand bend and is heavily scarred with pot-holes. As I bumped round this curve at about 40 m.p.h., imagine my horror to see the near-side door fly open and my small son precipitated out like a shot from a gun. My daughter started screaming from the back, and as I jammed on the brakes I felt that each bump might be his body. But small boys are tough, and by the time we had stopped the lad was picking himself up and shouting like the devil. I knew immediately he could not be much hurt, and running back to him I discovered that under a lot of dirt and a good deal of blood there were merely superficial grazes on both knees and the back of one hand. (It seems clear that we ought to start training our future parachutists at a very tender age.) I picked him up and put him in the car and drove back to the cottage with my daughter leaning over from the back and holding the boy firmly pinned in his seat for fear he should once more disappear. As I drew up at the cottage with a good deal of tooting on the horn, my wife appeared at the door, and with true feminine intuition, said as she looked me straight in the face: "He's fallen out."

I had to admit it, of course, and I did so rather nervously because she had told me several times that I must fit an additional fastener to the offending door, because there was no means of locking it. However, her relief at finding the boy unhurt saved me from recriminations, and after bathing and bandaging the grazes I took him off to school once more in the car, on the principle that a thrown rider should get back on his horse or a pilot should fly again as soon as possible after a crash. He came willingly enough, but insisted on sitting in the back, a decision with which I sympathised. But by the afternoon, when I went as a special act of thanksgiving to take the children home instead of leaving them to catch the country bus, he had recovered his spirits and insisted on sitting in front as usual. In fact he was feeling rather pleased with himself, because he had gained great kudos at school through embellishing the story (he is a born fisherman) by saying that he had fallen out while we were doing 65 m.p.h. and had been half-killed. But I was careful to buy an extra catch for the door on the way home and fix it on before I went in for tea.

* * *

When my brother-in-law brought home two cast-iron stoves he had won, I was delighted. Our house is an Early Victorian ice-box, and here was at last a chance of warming at least part of it. We installed and black-leaded the stoves and lit them. Smoke belched forth from all sides and they became just perceptibly warm. We consulted the experts and our worst fears were

Although so huge a number of soldiers were unnecessarily hors-de-combat as the result of sickness, this *actual figure* was not in itself particularly serious. For by the very nature of war only a small proportion of the fighting soldiers of an army are, at any one time, actually engaged with the enemy. Many may be in units in reserve, refitting, or retraining; others may be on leave, awaiting posting, or travelling from one theatre to another. The real gravity of the situation is to be found *in the disorganisation of units*. In reference to the Burma campaign, Marriott (1945) says:

> "The effect of disease in wasting man-power is not to be measured merely by arithmetical calculation of man-days lost—gigantic as has been this total. There must also be reckoned the effects due to disruption of units and the influence on morale. In the Arakan campaign in 1943 some units were losing their entire personnel, with replacement by reinforcements, every six to eight weeks. Imagine the task of commanders trying to operate forces, in the face of the already fearful difficulties of climate, terrain, and supply, with all their officers, N.C.O.s, and men constantly changing."

It was not, indeed, surprising that the campaigns of 1943 and 1944 in Burma were so unsuccessful.

I suggest that during a campaign all units should be encouraged, if local circumstances allow, to retain those of their acute sick who look likely to recover soon. As a corollary, the position of regimental M.O. should be considered one of the most important in the R.A.M.C., and confined to sound doctors of good personality. Even soldiers affected by certain mildly disabling disorders which are incurable while they remain on duty but curable in hospital (e.g., jungle sores and some other skin conditions, otitis externa, and many minor surgical lesions) may properly be retained with their units until these are withdrawn from the fighting line. Useless men whose presence adversely affects morale and endangers the lives of others should be disposed of through non-medical channels. Even if their units do not receive reinforcements to replace them, their disappearance will be a gain.

In Burma, in so far as the evacuation of sick and wounded was necessary, far greater efforts should have been made to prevent it from proceeding beyond field-ambulance level. Those brilliant and ingenious feats of air evacuation to base hospitals, which received so much publicity and appealed so strongly to the public mind, should, in general, have been reserved for the severely wounded and those with grave diseases such as typhus fever.

In England Now

A Running Commentary by Peripatetic Correspond

A LITTLE while ago, on the spur of the momen
exchanged our comfortable family
sports tourer. So far as cars are
the same mental age as my sm
together we agreed that the new old car was much
"sporty" than the old old car. Since then the
trip from our small country cottage into the unive
town, where he and my daughter attend school a
work at the hospital, has become altogether
adventurous. I will pass swiftly over the early
when the moribund batteries made starting diffi
and my unfortunate wife was dragged out to help
the car as fast as possible down a gentle slope to m
the engine fire; the discovery that the reason for
stiff and erratic steering was three broken leave
the near front spring, including the main leaf, which
attempting to perform its proper function in defia
of natural laws; and the unpleasantness of the
heavy rain when gouts of water poured on us thro
the threadbare canvas roof. The sequel to th
disturbing but relatively trivial events was m
alarming.

Starting off late (as usual) for school one day, I s
along our country road as fast as the cold engine wo
gather speed, but we had gone only a mile when disa
overtook us. The road there takes a gentle right-h
bend and is heavily scarred with pot-holes. As I bum
round this curve at about 40 m.p.h., imagine my hor
to see the near-side door fly open and my small
precipitated out like a shot from a gun. My daugh
started screaming from the back, and as I jammed on
brakes I felt that each bump might be his body.
small boys are tough, and by the time we had stop
the lad was picking himself up and shouting like
devil. I knew immediately he could not be much hu
and running back to him I discovered that under a
of dirt and a good deal of blood there were mer
superficial grazes on both knees and the back of one ha
(It seems clear that we ought to start training our fut
parachutists at a very tender age.) I picked him up a
put him in the car and drove back to the cottage w
my daughter leaning over from the back and hold
the boy firmly pinned in his seat for fear he shou
once more disappear. As I drew up at the cotta
with a good deal of tooting on the horn, my wife appea
at the door, and with true feminine intuition, said
she looked me straight in the face: "He's fall
out."

I had to admit it, of course, and I did so rather nervous
because she had told me several times that I must fit a
additional fastener to the c
was no means of locking it.
the boy unhurt saved me from recriminations, and
bathing and bandaging the grazes I took him off
school once more in the car, on the principle that
thrown rider should get back on his horse or a pil
should fly again as soon as possible after a crash.
came willingly enough, but insisted on sitting in th
back, a decision with which I sympathised. But by th
afternoon, when I went as a special act of thanksgivin
to take the children home instead of leaving them
catch the country bus, he had recovered his spirits an
insisted on sitting in front as usual. In fact he wa
feeling rather pleased with himself, because he had gaine
great kudos at school through embellishing the sto
(he is a born fisherman) by saying that he had falle
out while we were doing 65 m.p.h. and had been ha
killed. But I was careful to buy an extra catch for th
door on the way home and fix it on before I went in fo
tea.

* * *

When my brother-in-law brought home two cast-iron
stoves he had won, I was delighted. Our house is an
Early Victorian ice-box, and here was at last a chance o
warming at least part of it. We installed and black
leaded the stoves and lit them. Smoke belched fort
from all sides and they became just perceptibly warm
We consulted the experts and our worst fears were

mg.) with calcium phosphate (gr. 1), given six to hours after an initial dose of vitamin-K analogue mg.) with nicotinic acid (50 mg.), capped, so to the effect of the latter, rendering further dosage essary while giving the same guarantee of immunity.

I have not found that either vitamin P or calcium phosphate *alone has this highly desirable effect, and I* m unable to explain the action of the calcium phosphate, hough a connexion between vitamin P and blood-alcium has been suggested.[2] I should add, however, hat, in combination with vitamin P, in repeated doses nd in the above ratio, calcium phosphate appears to nhance the effect of the vitamin as a urinary sedative nd diuretic and also in rapidly relieving symptoms in he most acute cases of neuritis and fibrositis.

The above notes apparently suggest two different unctions of vitamin P—one affecting immunity, the ther bearing a more obvious relation to permeability.

The case of kala-azar quoted by Dr. Corkill, which as also being treated with antimony tartrate, should e considered in the light of evidence of some degree of ntitoxic effect of vitamin P in cases treated with organic rsenicals,[2] the close chemical analogy between arsenic nd antimony being suggestive.

It therefore appears possible that vitamin P exerts its pparent antitoxic or anti-infective effects by correcting preclinical or intraclinical increase in capillary permeability, thus reducing toxic absorption in cases of drug dministration and, in infective cases by the same echanism, allowing the body time to initiate antibody rmation. In this connexion the grave prognosis usually sociated with the hæmorrhagic and purpuric forms of fectious diseases is interesting and, as Dr. Corkill has ready suggested, invites further investigation.

Ffestiniog, Wales. D. MARCUS EVANS.

THE HEALTH OF NURSES IN HOSPITAL

SIR,—I would join with your correspondent, Dr. Brails-rd (Dec. 10) in the plea for greater concern for the health our nurses in hospital. The incidence of tuberculosis ay be greater in the nursing staff of general hospitals an that of the general population; but at least this ease occurs in a known group of staff, and if adequate dical care is provided the infection can be diagnosed rly and medical treatment started, with a consequent eater chance of recovery.

Over a period of four years' observation in Withington spital it was found that one-third of our entrants as ident nurses were Mantoux-negative. The number such Mantoux-negative reactors was 84, and of this mber 12 developed tuberculosis—i.e., 14%. During same time there were 172 primary positive reactors, whom only 2 developed tuberculosis—i.e., approxitely 1%.

f the hospitals find it impossible to prevent open es of tuberculosis being admitted to the wards, then s their duty to see that all known methods of detection the early lesion in their staff be applied. In the case the negative reactors in this hospital the test was eated each three months until conversion, and after t time a monthly body-weight and three-monthly ncal and radiographic examinations were made. o—and most important—these girls had impressed on them that they must report if they did not feel ll. Can one also hope that one senior physician be de responsible for the health of the staff, rather than ries of changing resident medical staff, for in my w this is one of the most important principles in nexion with the full medical care of nursing staffs hospital?

ithington Hospital, Manchester. J. M. GREENWOOD.

CEREBRAL PALSY

SIR,—The account by Dr. Agassiz and his colleagues of the early signs of cerebral palsy was most helpful. We should be interested to know what were the sources of their cases aged 6 months or under, and how many such infants have been diagnosed and treated. In Birmingham, where, at a special cerebral palsy clinic, we have seen over 200 cases a year for two years, we find it exceptional for the mother to have noticed anything wrong with her baby until the age of 6 to 9 months. Usually she has first consulted a doctor towards the end of the first year, when she is worried because the baby is not yet sitting up. Thus doctors seldom have the opportunity of diagnosing cerebral palsy in very young infants. Welfare doctors, who see infants in the early months, are not likely to look for the signs described by Agassiz et al. unless specially consulted about the child's backwardness, which, as mentioned above, the mother has probably not yet noticed. Backwardness, rather than stiffness and abnormal movements, has been the mother's first complaint in the overwhelming majority of cases. But so many normal children fail to pass the usual milestones at the age laid down in the textbooks that special clinics would soon be overloaded if every baby who is slow to smile or raise its head were referred to them.

An early case may occasionally be picked up at a follow-up clinic where infants who have suffered from birth injury or jaundice are studied. Such studies are at present being carried out in this department.

One other point: from our experience we feel that, in the past, too much stress has been laid on the discrepancy between the intelligence of spastics and athetoids. In a series of 340 cases where the intelligence was assessed, 49% of all cases had an intelligence quotient of less than 70, and the mean intelligence quotient of spastics and athetoids was not significantly different.

PATRIA ASHER
F. ELEANOR SCHONELL

The Children's Hospital, Birmingham.
Research Fellow, University of Birmingham.

SIR,—I feel that the observation made by Dr. Agassiz and his colleagues, that cerebral palsy associated with rhesus iso-immunisation is complicated by such severe mental retardation as to make treatment impossible or of no avail, should not be allowed to pass without comment. I have recently reviewed 36 cases of kernicterus which survived the neonatal period, the eldest patient being twenty-three years old. The more severely affected children developed a remarkable degree of extrapyramidal rigidity within the first six months of life; 9 of these died before reaching the age of three years; and it is cases which fall into this category, I presume, that Dr. Agassiz and his colleagues find to be virtually untreatable. The disability in the remainder varied from a mild chorea to a severe athetosis.

It has been difficult to forecast the ultimate extent of the physical handicap even when the child has reached the age of a year, and it has been impossible to be certain of the degree of mental impairment before the child has reached the age of four; the greater the child's physical handicap the older he must be before the level of intelligence can be adequately assessed. For example, at the age of eight, one severe athetoid was considered by a competent doctor to be a complete idiot and largely paralysed; at the age of eighteen he is still largely paralysed but he can now carry on an intelligent conversation, he has an extensive vocabulary, and he is the first to observe his diabetic mother's impending hypoglycæmia and to tell her to take a lump of sugar. Two other patients are earning their own livelihood, one as an usherette in a cinema and the other assisting in his father's shop. Two children are attending State

---

Bicknell, F., Prescott, F. The Vitamins in Medicine. London, 1947; [illegible] relief could be obtained if 25% of acute medical beds in general hospitals could be assigned for the admission of treatable cases of respiratory tuberculosis. These beds should be controlled by the physician in charge of the associated chest clinic. In coöperation with a thoracic surgeon, he can utilise his beds to the best advantage by a close combination of hospital and domiciliary supervision. It follows naturally that if economy in bed usage can thus be secured, a more efficient use of sanatorium beds could be achieved by similar administration.

The interests of many thousands of tuberculous patients will best be served by the evolution of a system whereby one physician will be responsible both for their inpatient care and outpatient supervision in the chest clinic.

Willesden, London, N.W.10. C. H. C. TOUSSAINT.

SIR,—In your issue of Dec. 10, eight distinguished sanatorium physicians deal with the suggestion that chest-clinic physicians should have personal control of patients under treatment in the sanatorium as well as at the chest clinic, and they describe this proposal as retrograde. They suggest that the sanatorium physician would thus be displaced and the care of patients given to juniors controlled by an occasional visit from the clinic physician.

If this were true it would be a step in the wrong direction. But we believe that there is no reason why the chest-clinic physician should not be on the staff of the sanatorium serving his area and be allocated a number of beds to deal with part of his waiting-list. These cases would be treated in collaboration with the sanatorium physician. Such beds should comprise only a limited proportion of the total sanatorium beds. The remainder would consist of units under the sole charge of the sanatorium physician, and in these he would be able to carry out his functions of teaching and research even more effectively than at present.

Patients could then be admitted when they were ready to obtain most advantage from sanatorium treatment and not when their names came to the top of the waiting-list. The clinic physician would no longer have to guess whether his patient would still be likely to require sanatorium treatment after ten months or a year, as at present, but would be able to integrate the patient's home and sanatorium treatment so that the one would be a well-planned continuation of the other.

The flexibility of such a scheme, which would allow home treatment, general hospital treatment, or sanatorium treatment to be deliberately selected as and when required, would go a long way towards lessening present sanatorium waiting-lists, which, as the writers point out, are also being continually increased by recent therapeutic advances. It would, however, by reason of the increased turnover of patients, put an added strain on the nursing staff.

Surely a policy like this would not impair the work of either branch of tuberculosis control but would link up sanatorium and clinic teams to their mutual advantage.

HUGH CLIMIE

Ealing Chest Clinic, London, W.13. PETER W. ROE.

SIR,—I agree with Dr. Ruth Dingley (Dec. 3) that we should not allow children to leave school with undetected tuberculosis; but for my part I favour annual examination of all school-children by mass miniature chest radiography. In the City of Nottingham it has been the practice since 1944 to X ray all school leavers and to X ray the children from grammar schools, high schools, technical schools, and colleges, and university students, as nearly as possible once a year. The following table shows the cases of tuberculosis found by this means in three grammar schools.

GRAMMAR SCHOOL A (MALES)

Year	*No. radiographed*	*No. of activ*
1944	134*	–
1945	288	–
1946	415	1
1947	736	1
1948	881	1

GRAMMAR SCHOOL B (FEMALES)*

Year	*No. radiographed*	*No. of activ*
1945	417	2
1946	375	–
1947	689	–
1948	682	–
1949	697	2

GRAMMAR SCHOOL C

	Males	*Females*	*Total*	*Active males*	*Active females*
1945	210	190	400	1	2
1946	204	164	368	1	1
1947	376	298	674	1	–
1948	55	38	93*	–	–
1949	320	272	592	–	–

* School leavers only.

The active cases of post-primary tuberculosis discov in these schools were completely unsuspected, in spit the excellent inspections of the school medical serv Unfortunately not all of them were early cases; some had bilateral disease. But the important thin that they were completely unsuspected! Neither v they all of school-leaving age.

In Grammar School B no active cases were fo during 1946, 1947, or 1948, but two cases were fo in 1949 and others are expected within the next years because in 1948 one of the teachers was founc have active pulmonary tuberculosis with a posi sputum. It is highly desirable that all teachers sho be radiographed with their classes.

To my mind, Mantoux-testing of groups of sch children is not a practical proposition, whereas m miniature chest radiography is ideally suited for t purpose, and can easily cope with large groups at rate of 100 volunteers per hour. The X-ray examinat is speedy and relatively inexpensive, and when scheme is carefully organised it interferes but little w the normal school routine.

Mass miniature radiography does *not* create a tuber losis phobia in children. It is our practice for somec to visit the school before the X-ray survey takes pl at each school to explain to the children what it is about, and the value of the examination. Most child would, I think, prefer a speedy miniature chest X-r examination to being "pin-pricked" for a Manto test.

VITAMIN P AND ANTIBODY PRODUCTION

SIR,—I was greatly interested to read in your is of Dec. 10 the letter from Dr. Corkill, in which he dra attention to the possible connexion between vitamin and antibody production in response to infection. I shou like to record some phenomena which may have so bearing on it and may also help to throw light on t ultimate physiological function of this vitamin.

In following up my earlier investigations into t effects of vitamin-K analogue in a number of min toxic and infective conditions,[1] I devised a simple a rapidly effective method of treating the common col which consisted in a six-day course of vitamin- analogue (10 mg. once daily) with nicotinic acid (50 m twice daily). In most cases so treated during the pa two years this routine has ensured immunity for abo three months. Later, while studying the effects vitamin P [illegible] conditions, I noticed a apparently [illegible] toxic states, and afte much experiment I found that a single dose of vitamin

---

1. Evans, D. M. *Practitioner*, 1946, 157, 391.

stiffness during the day, but we have not observed any lation to the time of the injection.

As Lewin and Wassén also noted the skin in the articular gion to be warmer and redder following the injections, serial in-temperature readings have been made, which do not nfirm their observations. One patient stated that he did el warmer after his second injection, and one sweated freely ter his second injection.

8 inpatients have received 5 mg. of deoxycortone acetate ramuscularly and 1 g. of ascorbic acid intravenously daily, r periods varying from four to fourteen days.

Of these patients, 3 are definitely worse and their injections ve been stopped; 3 are improved; and 2 are unchanged. f the "improved" patients, 2 walk more easily, and the d has increased strength in a previously badly affected rist. Only 1 of these cases has shown improvement greater an expected from simple physical treatment.

(c) Of the 2 outpatients, 1, a youth, aged twenty-two, with rly rheumatoid arthritis (joint-pain, no swelling or deformies) of moderate severity has had three combined injections. is pains disappeared one hour after the first injection and e remained pain-free for twenty-four hours. He received ree combined injections in one week and then stated that s pains had completely disappeared. Unfortunately in this se no objective measurements were possible. The other patient after two injections has shown slight improvement.

Briefly, then, of 17 patients, 4 are worse, 1 is better, nd the remainder show only the improvement expected om simple physical treatment. We intend to continue ith our therapeutic experiments under close observa-on. The main purpose of this letter is to indicate that ur preliminary trials do not support the optimism gendered by the original report of Lewin and Wassén.

S. J. HARTFALL
R. HARRIS.

Leeds.

SIR,—When the preliminary communication by the wedish workers Lewin and Wassén was published in our issue of Nov. 26, five active cases of rheumatoid thritis were in the Tindal General Hospital, and it as decided to treat them with deoxycortone acetate id ascorbic acid for a week. To obtain an unbiased inion, a surgeon saw each case before the treatment as begun, and again at the end. His findings are sed on the amount of pain and swelling in the worst ints, the degree of movement present, &c. All other eatment was stopped during the trial period, and the sage and duration of treatment were the same for ch patient, though cases 1 and 4 had, in addition to the ll course, a single preliminary injection of deoxycortone etate and ascorbic acid before the trial was begun; hile case 4 was so obese that all the injections were ven intramuscularly and it was impossible to complete l her investigations. It should be remarked that ewin and Wassén found that equally good results ere obtained if all injections were given intramuscularly.

The course of treatment consisted of three injections ily for the first 2 days; two injections daily for other 2 days: and then one injection a day for a rther 3 days, between Dec. 1 and 7, inclusive. The sage of each injection was 5 mg. of deoxycortone ctate in oil intramuscularly, followed within a few inutes by 1000 mg. of ascorbic acid (10% solution) travenously (the night doses on the first 2 nights ing given wholly intramuscularly). This is well up to e dosage recommended by Lewin and Wassén, and, anything, is higher than they consider necessary.

CASE 1.—A man, aged 27, with 4 years' history of pain nd stiffness in shoulders, wrists, knees, ankles, and temporo-andibular joints. Wasting of intrinsic muscles of hand. oor general condition.

Before trial: Shoulders, elbows, knees, and wrists involved, ith increasing deformity of hands. X-ray films of hands ggestive of rheumatoid arthritis. E.S.R. 15 mm./hr. Wintrobe); Hb 84%; B.P. 115/70 mm. Hg. Weight st. 9½ lb.

After trial: Less tenderness in all joints, especially the wrists, but no increase in range of movement. E.S.R. 3 mm./hr; Hb 80%; B.P. 135/80 mm. Hg. Weight 8 st. 7½ lb.

Patient's impression: "The injections make me feel happy. Feel a little better."

Surgeon's impression: Little subjective or objective improvement.

CASE 2.—A woman, aged 60, with 4 years' history of pain, tenderness, and swelling in the left shoulder and both feet. Later both hands and right knee involved. Poor health.

Before trial: Pain and tenderness in right elbow, both wrists, and right knee and ankle; with wasting of hand muscles. X-ray films show cystic changes in heads of metacarpals. E.S.R. 50 mm./hr; Hb 87%. Serum-sodium 315 mg. per 100 ml. Weight 9 st. 10½ lb. B.P. 140/75 mm. Hg.

After trial: Practically no change. E.S.R. 40 mm./hr. Hb 83%. Serum-sodium 345 mg. per 100 ml. Weight 10 st. 1½ lb. B.P. 135/80 mm. Hg. A trace of œdema.

Patient's impression: "It makes me feel cheerful. Otherwise no effect."

Surgeon's impression: No subjective or objective improvement.

CASE 3.—A woman, aged 67, with 2 years' history of pain and stiffness in knees; later shoulders and hands involved. Complicated by pernicious anæmia and Raynaud's phenomenon in hands.

Before trial: Pain and stiffness in wrists, some wasting and ulnar deviation of metacarpals, with poor finger-flexion. X-ray films of knees show osteo-arthritic changes; wrists show much decalcification suggestive of rheumatoid arthritis. E.S.R. 35 mm./hr.; Hb 91%. Serum-sodium 350 mg. per 100 ml. B.P. 140/75 mm. Hg. Weight 10 st. 2½ lb.

After trial: No change in joints. E.S.R. 12 mm./hr: Hb 85%. Serum-sodium 310 mg. per 100 ml. B.P. 160/90 mm. Hg. Weight 10 st. 3 lb.

Patient's impression: Injections make her feel happy. Otherwise no change.

Surgeon's impression: No subjective or objective improvement.

Note: This patient presents all the appearances of rheumatoid arthritis, but we think it just possible that she may eventually prove to be a case of lupus erythematosus (disseminata) despite the absence of skin lesions at present.

CASE 4.—A woman, aged 45, with 15 years' history of pain in shoulders, arms, and ankles, with marked limitation of movements and ulnar deviation of metacarpals. Increasing obesity since 1940.

Before trial: Pain in shoulders, wrists, and ankles. No movement at elbows, no pronation-supination, and practically no movements of thumbs and ankles. Marked tenderness. X-ray film of elbow shows osteo-arthritis with rheumatoid changes.

After trial: Very little pain in joints. Slightly increased movements of elbows, thumbs, and ankles.

Patient's impression: Very pleased. Injections make her cheerful.

Surgeon's impression: Not very much real change.

CASE 5.—A woman, aged 60, with 3 years' history of pain and stiffness in hands and knees. Has felt poorly, and since April, 1949, has spent most of the time in bed.

Before trial: Pain and tenderness in right shoulder and wrists, and wasting of hands. Much swelling and pain in knees and ankles. X-ray films of wrists show fairly advanced rheumatoid arthritic changes in carpus. E.S.R. 53 mm./hr.: Hb 67%. Serum-sodium 340 mg. per 100 ml. Weight 6 st. 10 lb. B.P. 110/70 mm. Hg.

After trial: Less pain and no tenderness in shoulders, wrists, or knees, with increased range of movement in left knee. E.S.R. 40 mm./hr.; Hb 76%. Serum-sodium 330 mg. per 100 ml. Weight 6 st. 11½ lb. B.P. 120/75 mm. Hg.

Patient's impression: Greatly relieved. Life is worth living once more. Treatment made her cheerful and she has been sleeping and feeling better.

Surgeon's impression: Marked subjective and some objective improvement.

schools and another a private school. Of those over the age of four whose intelligence quotients have been assessed, 6 out of 15 have an intelligence quotient of 70 or over, the best 3 being 100, 98, and 95, while 6 have intelligence quotients of 50 or less.

I fully realise that children with kernicterus are often mentally retarded, but to summarily dismiss a severe case, especially in infancy, as being hopelessly mentally deficient is fair neither to the parents nor to the child.

JOHN GERRARD
Lecturer in Pædiatrics,
University of Birmingham.

IRON POISONING

SIR,—Will you allow me to add the following case to the most interesting series mentioned in your columns.[1]

On April 23, 1949, at 2 P.M., a healthy 14-month-old male child, while left alone for half an hour, swallowed 30 'Fersolate' tablets. On re-joining the child, the mother noticed that he was in pain, and fortunately perceived at once that he had swallowed the tablets. She administered an emetic of salt and water. The child was sick twice and brought up 15 tablets with the coating still intact.

He was admitted to hospital forthwith and the stomach was washed out, considerable quantities of iron being removed. On admission, his colour was poor and the pulse was weak and rapid. By 8 P.M. his colour and pulse were normal and he appeared to have recovered. He had a good night, and next morning seemed little the worse for his mishap, being discharged to his home later in the day.

The cases you listed have been a salutary reminder to me of the potential gravity of the above case.

North Devon Infirmary, Barnstaple. R. M. J. HARPER.

OBSTETRICAL BRAINS TRUST

SIR,—Though Dr. Hugh Jolly (Dec. 10) may have the support of the *Oxford English Dictionary* in stating that the first ovulation (or the occurrence of spermatogenesis) marks the exact beginning of puberty—"the state or condition of having become functionally capable of procreating offspring"—I venture to suggest that this definition often becomes unworkable. Would Dr. Jolly, for example, regard a woman of 25, whose menarche occurred at 13 but who has had only anovular cycles, as prepuberal; or a man with fully developed accessory sexual organs, but with azoospermia not of acquired type, as similarly prepuberal? The position in circumstances such as these (which are not purely hypothetical) is surely untenable. Indeed, the *O.E.D.* definition breaks down more completely and more frequently than does Dr. Jolly's; for according to the former, a woman with blocked tubes, or a man with blocked vasa deferentia, being "functionally incapable of procreating offspring" would ipso facto be excluded from the state of puberty.

I think the clue to the problem lies in the fact that the gonads have a dual function: they produce both sex hormones and gametes, and whereas there may be hormones without gametes there are never gametes without hormones. Morphologically and psychologically the changes traditionally associated with puberty depend on the incretory function of the gonads; only the reproductive function depends on gametogenesis. Hence it seems illogical to deny the status of puberty to an individual who differs from one accepted as puberal solely in the failure to produce gametes. The fact that the incretory function of the ovary precedes gametogenesis is recognised by the distinction sometimes made between "puberty," defined as the morphopsychological state resulting from the action of the sex hormones, and "nubility," the condition in which gametogenesis is also occurring (strictly meaning "marriageable"). It seems reasonable, therefore, to regard puberty as dependent on the action of the sex hormones and independent gametogenesis; in which case Dr. Jolly's differentiat between sexual precocity and precocious puberty becor little more than a quibble.

Hospital, London, W.C.1.
G. I. M. SWYER

CHILDREN REFERRED TO THE PSYCHIATRIS

SIR,—It does not seem to me that Dr. Mood explanation (Dec. 10) of the persistence of enur nocturna will hold water—if you will pardon the metap Taken literally, it would imply an "automatic bladd whereas the condition is nothing like that. The enur is nocturnal, which means that inhibition must functioning satisfactorily, on the whole, in the daytin in fact, there clearly *is* what Dr. Moodie calls "a defi sensory impulse," and in the absence of some spe abnormality in the nervous system there is no physi reason why it should not give warning in sleep as v as in waking life. If it fails to do so, we are justif in regarding the symptom, from the point of view treatment, as psychological. A small bladder, whet inherited or acquired, may be a slight handicap, si it demands more of the patient than mere inhibiti —he must actually get out of bed. But I do not see h otherwise than psychologically Dr. Moodie would tr it, short of blowing it up through a catheter. I assume, course, that a training procedure would be classed a form of psychological treatment (though an etymolog might argue that point).

Much the same may be said of crossed cereb laterality, to which Dr. Moodie attributes many cases stammer and backwardness. Whether given or n I suggest it should be regarded merely as a slig handicap, which is of little or no real importance adult life, but which can be made to loom very la in the mind of the child, as indeed can almost anythin

THE TONSIL AND ADENOID PROBLEM

SIR,—I wish to draw your attention to an erro one word in your report (Dec. 10, p. 1087) of my rema at the Royal Society of Medicine on Dec. 2. This occu in the last sentence, where I am quoted as having said "For over two hundred years tonsillectomy has prove a beneficial operation." I actually said "two *thousan* years."

Oxford. RONALD MACBETH.

DEOXYCORTONE ACETATE AND ASCORBIC ACID IN RHEUMATOID ARTHRITIS

SIR,—With the supplies of 'Cortisone' restricted a they are in this country at the moment, many rheumato logists will have been anxious to confirm the prelimina report of Lewin and Wassén in your issue of Nov. 26.

In the last three weeks we have investigated the effec of this therapy on 17 patients, all cases of rheumatoi arthritis. The results have been disappointing; we hav never seen anything like the response obtained wit cortisone in rheumatoid arthritis as demonstrated to on of us at the Mayo Clinic earlier this year.

The cases were in three groups: (*a*) 7 inpatients i Harrogate; (*b*) 8 inpatients in Leeds; and (*c*) 2 outpatient in Leeds—all under the care of one of us (S. J. H.). W may summarise our results as follows:

(*a*) 7 patients have received combined deoxycortone-acetate (DOCA) and ascorbic-acid therapy, in the dosage suggested by Lewin and Wassén, daily for eleven days. They have also had basic minimal physical treatment.

Of these patients, none have shown improvement greater than expected from the simple physical treatment they have received; one is rather worse. Several have shown variations the end of 9–10 minutes a regular heart-beat was hed. After the operation the patient's colour good and his pulse fair. He did not, however, start again, and artificial respiration had to be The patient's general condition gradually ated and he died at 2.15 A.M. The anæsthetist d: "I was engaged on another operation when the supply of oxygen was going low. I called and told her. She went out and called a porter. mpty oxygen cylinder was removed from the and the other substituted. I took it for granted hen I asked for oxygen I would get it."

Parliament

QUESTION TIME

Medical Services in Malaya

el M. **Stoddart-Scott** asked the Secretary of State if he would make a statement with regard to the services provided for British troops in the Malayan n; and if he would state what improvements could ected in the immediate future.—Mr. **Emanuel** LL replied: The medical services in Malaya include uate number of Service hospitals and medical officers tain the normal health of the troops and to care for and wounded. Difficulties, however, arise in securing ediate surgical treatment of battle casualties. Since is carried on by numerous small columns of troops perate in difficult country and are frequently on the it is impracticable to provide surgical facilities for out operations in the immediate vicinity of the Consequently it is necessary for casualties to be ed to the hospitals where surgical attention can n.

are three Service hospitals in Malaya district, which the mainland of Malaya, but there is only 1 Army and it has accordingly been necessary to utilise the of civil surgeons. In Singapore island there are ervice hospitals and 3 Army surgeons. To meet the cy of surgeons in the Army as a whole, arrangements een made to engage immediately a number of civil s for short-term contracts. Three have already d the terms and conditions of service, and, subject being physically fit, will be sent to the Far East as possible to complete the establishment in that theatre. evacuation of casualties presents great difficulties in f the nature of the country, and efforts have been or a considerable time to devise a suitable means of sport from the jungle to the nearest hospital. Various ave been undertaken and work is now proceeding on dification of three helicopters to make them suitable task. They should arrive in Malaya in April, 1950. meantime, the effects of delay before surgical treatment are being minimised, as far as possible, by the use of penicillin and other drugs.

Colonel **Stoddart-Scott**: Can the Minister say why the first announcement that the War Office made was that there were 7 surgeons active in the Malaya district when the establishment is only for 3 and there is actually 1 surgeon functioning? Would the Minister say why it was not possible to have evacuation by air before next April?—Mr. **Shinwell**: The public relations department of the War Office were correct in the statement they made. They referred to the strength in the whole area, and that was 7. There is one in the Malaya district, 3 in Singapore, and 3 in Hong-Kong. They referred to the whole theatre and not to Malaya in particular. That was what was said and, so far as this was concerned, they were correct. Nevertheless, I agree that it is insufficient, and we are taking all possible steps to deal with the situation.

Mr. **Anthony Eden**: Could I ask the Minister about the helicopters? I understood last March when I was there that they were soon to be expected. Why is it that it cannot be until next April that these helicopters are to be there?—Mr. **Shinwell**: I regret very much that difficulty in this connexion. We were promised the helicopters last March or April, but unfortunately it was discovered that the type of helicopter which was to be made available was unsuitable and modifications have had to take place ever since. I cannot hope to procure them before March or April.

Mr. **Somerville Hastings**: Can the Minister say whether there are not capable surgeons in the R.A.M.C. who could be flown out there at once so that, at any rate, there might be a sufficient number of surgeons able to deal with those who are wounded?—Mr. **Shinwell**: First, I must emphasise that we have experienced no serious difficulty in Malaya. Attention has been drawn to the shortage of surgeons, but it must not be assumed that anything serious has resulted from that shortage, although at the same time I regret the shortage. On the question of flying surgeons from the R.A.M.C. out to Malaya: unfortunately, for some considerable time we have had to give attention to the shortage of surgeons in this country and in other theatres.

Mr. **Quintin Hogg**: The Minister in his first answer concentrated almost entirely on surgeons. Can he give us some idea of other medical attention available? For instance, how long does it take for the casualty to get back to a R.A.P.? Are there casualty-clearing stations and advanced dressing-stations? What is the general picture? Mr. **Shinwell**: The hon. gentleman must not be hot and bothered about this. There is no occasion for engendering heat about it. We want to deal with this matter as speedily as possible, and that is precisely what we are endeavouring to do. As regards the availability of medical services—dressing-stations and the like—the position is by no means unsatisfactory.

Dr. S. **Segal**: Can the Minister say how many surgeons in this area hold consultant status; further, could he not perhaps look into the matter of offering adequate remuneration in order to procure the highest possible type of surgeon-specialist to be flown out to that area?—Mr. **Shinwell**: We are in fact offering excellent terms to civilian surgeons in this country. For service abroad we are offering from £1800 to £2200 a year, according to qualifications. In addition, they will receive a foreign-service allowance and an outfit allowance. On the whole, the terms are rather good.

Colonel **Stoddart-Scott** gave notice that in view of the neglectful attitude of the War Office in this matter he would raise it again on the adjournment of the House at the first opportunity.

Medical Standard of Recruits

Replying to a question Mr. **Shinwell** stated that the number of National Servicemen taken into the Army between Nov. 1, 1948, and Oct. 31, 1949, was 114,856. In the same period 5506 National Servicemen were discharged on medical grounds and 229 died.

Examiners of Food Handlers

Mr. **Charles Taylor** asked the Minister of Health whether, in view of the model by-laws which he had issued to local authorities in England and Wales to ensure cleanliness in the handling, wrapping, and delivery of food, he would make an order giving employers the right to insist on bacteriological examination of employees engaged in these businesses.—Mr. **Arthur Blenkinsop** replied: I know of no powers under which such an order could be made.

It will be seen that in cases 1, 2, and 3 the surgeon could find little or no improvement and these patients themselves noted no convincing improvement either, though in cases 2 and 3 there was a slight fall in the E.S.R. and in case 1 a fall which was so marked that we are doubtful of the accuracy of the reading. In cases 4 and 5 the patients considered there was an undoubted slight improvement, as did the surgeon in case 5. In case 5 also there appears to be a significant fall in the E.S.R. and the most striking clinical results have been obtained.

Three patients (cases 1, 3, and 5) spontaneously remarked that the injections made them feel more cheerful; the other two cases said the same on direct questioning. The blood-pressure rose slightly in all 5 cases, though hardly significantly. Case 2 gained 5 lb. in weight, developed slight œdema, and had an increased serum-sodium at the end of treatment, suggesting that continued treatment at that dosage might carry certain risks with it.

Our own and the ward sisters' impression of the results broadly correspond with the surgeon's and the patients', and have proved disappointing. We are fairly confident that the injections produced a temporary euphoria, which was even remarked on by other patients, and it is possible that this euphoria played a large part in the improvement noted in cases 4 and 5. In no case could the claims of great benefit put forward by Lewin and Wassén be confirmed. On the present evidence we would advise against the indiscriminate use of this treatment in such cases until further work has been done on it.

V. LLOYD HART
Physician.

F. STARER
House-physician.

Tindal General Hospital,
Aylesbury, Bucks.

SIR,—We were most interested, and instructed, by Dr. Kellgren's letter of Dec. 10. We were surprised to read that he had had such bad results in a series of 5 cases of rheumatoid arthritis treated with deoxycortone and ascorbic acid as described by Lewin and Wassén, while we were having good results in a series of 23 cases. We have made verbal inquiries of other workers and hear that some are having failures and some successes. For this incongruity the following explanations are possible:

1. *Differing selection of cases.*—This appears improbable, for we have heard of one worker who has had 11 failures in 11 cases of polyarthritis, whereas we have only had 2 failures in 23 cases. We did no case selection, but treated all cases as they became available at the rheumatism clinics and hospitals we attend.

2. *Unconscious psychotherapeutic suggestion.*—We believe we have now made enough controlled observations to exclude this possibility.

3. *Differences in technique.*—In a treatment which depends on the interaction of two drugs technique is clearly of the greatest importance. It seems that the deoxycortone must be available in muscle at the time the wave of intravenous ascorbic acid occurs. The work so far done suggests that the blood-level of ascorbic acid must be raised to between 5 and 10 mg. per 100 ml. Such a level is obtained by an intravenous injection of 1 g. but begins to fall off at once. So if the deoxycortone is not available no result need be expected.

Two cases of rheumatoid arthritis under the care of one of us (G. E. L.) in hospital were treated on the same occasion, the intramuscular injections being given by a nurse. (Until then we had been in the habit of giving our own injections.) In the first of these two cases it was noticed that the injection was given into the outer upper third of the buttock by a vertical stab. In this case there was a good response with loss of pain the full extension of a knee which had had a small *fl* deformity for two years. In the second of these two it was noticed that the deoxycortone injection given diagonally into bunched-up flesh. There wa response whatever. Three days later this second pa was treated again, care being taken that the deoxycor was given intramuscularly. On this occasion there some response, pain was partly relieved, and wal was somewhat easier. The result was not convir but suggestive. Since then one of our patients who previously responded very well has been given deoxycortone subcutaneously, and no response follo

We appreciate that on this scanty evidence it is proven that the deoxycortone must be given into mu and not fat, but it seems probable that the actio altered by the site of the injection. We hope soo have evidence which will decide this point. Meanwhi does seem important that observers should take partic care over the intramuscular injection. It shoul course always be given into the lateral aspect of the th for, as is well known, many injections in the butt go into fatty tissues. We feel that failure to pay s attention to this detail may be the cause of some of incongruities which are arising.

GEOFFREY E. LOXTO
DAVID LEVAY.

London, W.1.

Medicine and the Law

Burns from Unguarded Fires

WRITING on the Prevention of Burns and *Scalds* our issue of July 30, Dr. and Mrs. Leonard Colebr showed how perilous to children are electric and gas f which have no guard to prevent inflammable clot catching alight. At an inquest reported in the *Manche Guardian* of Dec. 13 Mr. Jessel Rycroft, the Manches city coroner, said: "This is the seventh electric fatality I have investigated in the last few months. have already appealed to the authorities to take act and it is time somebody woke up and did somethi about it."

The Wrong Cylinder

On Dec. 6 the Norwich coroner investigated the dea of a 58-year-old man who died after nitrous oxide w administered from a cylinder which was mistaken believed to contain oxygen. At the inquest, accordi to the *Eastern Daily Press* of Dec. 7, a senior surgi registrar said that when he saw the patient, who had perforated peptic ulcer, he decided that immedia operation was necessary. During the operation t sister said that the patient's pulse had stopped. opened the upper abdomen and massaged the hea through the diaphragm; it began to beat again. T perforation was sutured and the incision closed.

The anæsthetist, a junior registrar, said that befo the operation the patient was shocked and showed sig of mild chronic bronchitis. Anæsthesia was begun 5.45 P.M., and induction was uneventful. About 3 minutes before the patient was brought into the operatin theatre the oxygen cylinder became empty; he imm diately turned on what he thought was the spare cylinde which had been renewed by a theatre porter during th previous case. When the patient was brought into th operating-theatre, he was noticed to be cyanosed. "I was placed on the operating table at 6.1. Becomin alarmed at his general condition, I shut off everythin except what I thought to be the oxygen supply an administered artificial respiration, but within one and half minutes the heart failed. I found out that wha I thought to be a cylinder of oxygen was in fact nitrou oxide. This was at once remedied."

Notes and News

AN AMERICAN VIEW

October Dr. Willard C. Rappleye, professor of medical in Columbia University, New York, made an study of the British health service. In a report to h Macy jun. Foundation, he remarks on "the spirit of coöperation and the earnest efforts of the the hospital authorities, the local authorities, the boards, the Ministry, and the public to implement Service in a manner satisfactory to all concerned." In National Health Service the broad programme of pre- medicine has been handicapped by the greatly d remuneration in the clinical services. "Perhaps the serious difficulty at the present time is the reduction in number of full-time medical and dental officers because of increased opportunities and rewards of specialist, con- t and hospital staffs. This has been reflected in the reduction in the number of students enrolled in of Public Health, for example." As regards general rs, there has been a certain reduction in the and incentive for self-development, and a loss of for some: "the conscientious practitioner, can render very much more satisfactory services previously, although he is handicapped by the avy demands on his time for certificates, reports, and scriptions."

Most people consulted by Professor Rappleye believed that supply of doctors was adequate for the population, but he distribution of physicians "is quite faulty in some areas." The number and quality of men seeking to study medicine, he was informed, have not changed since the service started. Every medical-school authority consulted was of the opinion that practically all students intend to try to qualify r specialist status. "However, since only about one- ard of the physicians completing their registrarships can pect to obtain appointments as consultants . . . it is pected that the economical and professional pressure will ter increase sufficiently to persuade many recent graduates go into general practice. As soon as all available consultant tions are filled the number of such posts vacated annually y be 20% or even less of the output of medical schools." found general agreement that the service is operating "on asonably satisfactory basis under all the circumstances in at Britain, including particularly the serious conditions of national economy. . . . The real test of the National alth Service is ahead. Its future will be determined not doctors, medical schools, or hospitals but by the over-all nomic, social, and financial condition of the Nation."

THE RADCLIFFE CODE

HOUSEMEN and registrars at the Radcliffe Infirmary, ford, have been provided with some bedside reading in e new "handbook," designed, the Regius Professor of dicine says in his foreword, to tell them "how to do ngs, where to get things, who is who, and what is what." s it does, especially the last; for after some historical tes and a list of the staff it turns at once to the by-laws d instructions. "Each Registrar and Resident House ficer" says the first, "shall receive from the Administrator copy of this Handbook when he enters upon his duties, shall acknowledge its receipt by signing the book provided hat purpose." The newcomer is then directed to give his ble attention to his work for the Infirmary; told who dismiss him, what he must do if he wants permission eep out, and how many guests he can have to dinner; is (very properly) required to join a medical protection iety. These peremptory rules of conduct mastered, the ung house-officer and the slightly older registrar may n for solace to the pages which follow. They will find it, —not because the style is any more conciliatory, but ause the matter is so good. The chapter on note-taking uld be redundant if the houseman has been properly ined as a student; but this aspect of his work is often glected by his busy seniors, and he may never have acquired e necessary good habit. The detailed instructions given re should make his notes a model. A description of the llection of specimens for the clinical pathology and the hemical laboratories follows, and there is a short chapter the preparation of patients for X-ray procedures. A few tes on the anæsthetics department, the dispensary, and ne miscellaneous topics end a book which is packed with ful stuff but would be improved, we think, by putting the instructions and by-laws last. After all, even housemen are human, and registrars are only a little lower than the angels.

FOR THOSE ENGAGED IN SOCIAL WORK

SINCE the war ended, laws have changed so much and social services grown so much that the National Council of Social Service have been obliged to revise their handbook[1] completely. The new edition has been planned to form a companion volume to *Voluntary Social Services*, the second edition of which appeared last year. The handbook gives a great deal of useful information about public health and social services, housing, child care, education, amenities (such as parks, civic restaurants, art galleries, and broadcasting), industrial services (including the employment of the disabled), town and country planning, war pensions and allowances, the work of the courts of justice, the juvenile courts, the probationary system, and the prison service. Occupational diseases seem somehow to have slipped out of the net; but otherwise the handbook is thorough and informative, and every social worker will want a copy.

TRIBUTE TO DR. WILFRED HARRIS

A SPECIALLY pleasant function took place on Dec. 12 at Claridge's Hotel when a party of sixty assembled to do honour to Dr. Wilfred Harris on his 80th birthday. The party consisted of members of the staffs of St. Mary's, the Maida Vale, and the National Hospital, and there were many old house-physicians and registrars of Dr. Harris present. After the reading of a poem of praise by Mr. Zachary Cope, tributes were paid to the guest of the evening by Dr. Gordon Holmes, F.R.S., Dr. F. M. R. Walshe, F.R.S., Dr. Russell Brain, and Lord Moran; and the standard of postprandial oratory was very high. Dr. Harris in reply dwelt on his early days in neurology and his association with great figures of the past such as Hughlings Jackson, Charlton Bastian, and Victor Horsley. The evening terminated with a presentation of a set of Elizabethan spoons to the guest, who revealed himself as expert in antique silver as in matters neurological. The assembled company departed with a yearning to reach the age of 80 possessed of the same clarity of mind and activity as that of their guest.

FULBRIGHT TRAVEL GRANTS

THE United States Educational Commission in the United Kingdom offer these travel grants to citizens of the United Kingdom and Colonies to go to America for an academic or educational purpose, such as study, research, or lecturing. Applicants must have a guarantee of financial support in dollars in America for their stay; undergraduate and post-graduate students must show proof of admission to an American institution of higher learning, and all applicants, whatever their programme in America, must be definitely affiliated with such an institution. But applications may be made by candidates who have not yet concluded the above financial and institutional arrangements, and in certain rare cases of exceptional merit the commission will try to help obtain dollar support or institutional connexion. Preference will be given to candidates who intend to stay nine months or more, but applications for shorter periods from well-qualified persons who cannot be spared from their present activities for so long will be accepted. Grants cannot be given for attendance at conferences alone. These grants are available for travel to America between June 1, 1950, and May 31, 1951: they will cover the cost of return rail and steamship fares between the candidate's home in the United Kingdom or Colonies and the destination point in America. Further particulars may be had from the commission, 55, Upper Brook Street, London, W.1.

CONVALESCENT HOMES

EARLIER this year regional boards were asked to undertake, in association with local health authorities, a survey of all untransferred convalescent homes, with a view to their allocation for use either by the board or by the local health authority. As a result of consultations between the Ministry of Health and the County Councils' Association and the Association of Municipal Corporations, these arrangements are to be modified. Boards are now asked to undertake, instead, only a fact-finding survey of the untransferred homes, placing them in the following broad categories:

---

1. Public Social Service: Handbook of Information on Services Provided by the State. 8th ed., 1949. Pp. 128. Cloth 7s. 6d., paper 5s. Published by the National Council of Social Service, 26, Bedford Square, London, W.C.1.

Grants to Medical Students

In answer to a question Mr. GEORGE TOMLINSON stated that the Ministry of Education was prepared to consider extending, for a period of 6 months in the first instance, an award under the Further Education and Training Scheme to a medical student appointed to a resident post in order to supplement his salary if the circumstances justified it.

Dr. S. SEGAL: Could not newly qualified doctors be encouraged to undertake posts as trainee practitioners with doctors in general practice while waiting for their hospital appointments?

Education of Handicapped Children

In reply to a question Mr. TOMLINSON stated that since Jan. 1, 1946, 53 boarding special schools, exclusive of hospital schools, had been opened with accommodation for 3300 pupils, and he estimated that 30 more, with accommodation for about 1500 pupils, would be provided by the end of 1950. During the same period, 39 new boarding homes with accommodation for 917 pupils had been approved. No new training centres for handicapped persons had been provided under the Education Acts, and no additional provision was expected next year. The training facilities provided by the Ministry of Labour under the Disabled Persons (Employment) Act, 1944, were available for handicapped pupils when they left school.

Employment of Epileptics

In answer to a question Mr. GEORGE ISAACS stated that at Oct. 17, 1949, there were 14,370 epileptics registered as disabled persons of whom 1732 were unemployed. Epileptics, if suitable for ordinary employment, were eligible for all the training facilities provided for disabled persons, at Government training centres, at technical colleges, and with employers. If they required sheltered employment they could obtain training and work in 'Remploy' factories.

Smoke Abatement

Mr. A. R. BLACKBURN asked the Minister of Health to what extent local authorities during the past five years had taken powers to control and reduce smoke pollution of the atmosphere in the areas for which they were responsible; and what steps were being taken by him to promote further progress in this matter.—Mr. A. BEVAN replied: 8 local authorities have taken powers to establish smokeless zones, 17 to control the emission of smoke from new furnaces, 18 to provide district heating: the City of London has taken power to extend its by-laws for regulating smoke. I have asked all local authorities who are installing solid-fuel appliances in their new houses to select those of improved types which will burn smokeless fuel and I have approved a small number of experimental district-heating schemes.

Obituary

THOMAS ALBERT HINDMARSH

M.S. DURH., F.R.C.S.

Mr. T. A. Hindmarsh, surgeon to the Royal Victoria Infirmary, Newcastle upon Tyne, died on Dec. 8 at the age of 60.

He graduated M.B. with honours from the University of Durham in 1911 and he held house-appointments at the Royal Victoria Infirmary under Rutherford Morison before serving throughout the 1914–18 war. After a period in general practice in Cumberland he returned to Newcastle where he settled in consulting surgical practice. In 1919 he took the M.S. with first-class honours and in the same year he obtained the F.R.C.S. He joined the staff of the Royal Victoria Infirmary to serve as assistant surgeon first with R. J. Willan and later with Professor Grey Turner. He was also on the staff of the Whickham Cottage Hospital, Hexham War Memorial Hospital, Alnwick Infirmary, and the Palmer Memorial Hospital, Jarrow.

G. A. M. writes: "'T. A.' or 'Thomas Albert,' as he was called, personified the Northumbrian approach to surgery. Without showmanship or eloquence, perhaps at times somewhat naive, he was yet well able to take a full and useful part in surgical discussions. Indeed on occasion, drawing upon his vast experience, he could do so with devastating effect. His contribution to the discussion on toxic goitre at the Oxford meeting of the Association of Surgeons stole the show and was virtually a personal triumph. He did a tremendous amount of hospital work, besides having a large private practice; but, despite these distractions he was an omnivorous reader of current surgical literature and an enthusiastic member of a surgical travelling club. His work was always up to date and his theatre drew many visitors. It is especially sad that he should die just when he was rearranging his life to devote himself to the more academic side of surgery and place the benefit of his experience at the disposal of those now being trained. Universally popular, a keen golfer and fisherman, and with an enormous fund of good stories, he had a host of friends and almost certainly no enemies. Although I was not a close personal friend I feel impelled to record this appreciation because T. A., typically, once went out of his way to help me to start in a branch of surgery in which he himself was not entirely disinterested. Such actions account in part for the great affection in which he was held and because of which he will be remembered by many."

His old chief, G. G. T., adds: "Albert Hindmarsh was a good sound general surgeon with a very wide knowledge of the art. Though his tastes were far too catholic to be limited to any one branch of work for years he had done a great deal in caring for toxic goitre in which he had a very large experience and in which he was particularly successful. He was always cheerful and optimistic and devoted to his patients. Of recent years he often seemed to be called upon to operate on professional friends and he was widely trusted. A hard worker, he was never reluctant to undertake new duties, and his activities covered a wide area in the North Country. He was a loyal colleague and fast friend. Quite recently he had been appointed as examiner in the final fellowship, but alas he had not yet taken his place on the court when he died.

Dr. JUSTINA WILSON

IT was a fortunate chance that, owing to her husband's early retirement from work in India, Dr. Justina Wilson returned to England. After travelling widely in Europe and studying physiotherapy in Germany and Sweden, she founded her school of massage in Baker Street about 1909. Later she fused this with the Swedish institute in Cromwell Road, which had been founded by Dr. Mary Hawkes, who herself was a pioneer in introducing Swedish methods of physical medicine into this country. Dr. Wilson thus became connected with [illegible] the Royal Free, and, later, St. Mary's [illegible] When she found the lack of a medical qualification impeding her beloved work, she started as a medical student and qualified in 1916. At this time she was directing the Swedish institute, and she had started in private practice—truly a task that would have daunted most people.

She was always young in mind, ready to try any new ideas in her work, though a staunch Conservative in her politics. Her reputation was international and she was consulted widely by clinicians abroad. Each year she tried to spend some time travelling in Europe, and on these journeys bought any piece of apparatus or new gadget which appealed to her as likely to help her work. She was a pioneer of—among other things—short-wave pelvic diathermy, especially for patients suffering from chronic inflammatory states and sterility. This led her to study and practise endocrine therapy, which she always tried to base firmly on scientific data since she considered that this subject was open to "quackery."

Her private practice was very wide in its scope, especially during recent years, and she brought to the relief of her many patients a wide experience, an expert knowledge, and an immense fund of kindness and sympathy. She did not suffer fools gladly and had a caustic tongue with a flow of language that was presumably derived from her Irish ancestors. Dr. Wilson was essentially an individualist in her methods of treatment and in her acceptance or rejection of current ideas; but she constantly disclaimed anything that appeared to her sham or merely expedient.

During the late war she worked excessively long hours in London, and each weekend journeyed down to Eastbourne to spend a short time with her invalid husband; it was only after his death in 1948 that her will to work and live diminished.

G. M. S.

TEMPOROMANDIBULAR ARTHROSIS *

JENS FOGED
M.D. Copenhagen
FORMERLY PROFESSOR OF SURGERY IN THE DENTAL SCHOOL OF COPENHAGEN

A SURGICAL lesion of the temporomandibular joint that the practitioner is likely to meet fairly often and of which we have had considerable experience in our department is temporomandibular arthrosis. The clinical picture seems to have been but relatively little known until recently, owing to the slight interest shown by pathologists in the temporomandibular joint compared with that shown in other joints, though functionally the temporomandibular joint is one of the most important joints in the body, playing a chief rôle in the intake of food and hence in the general physical condition.

This lesion is usually called temporomandibular cracking, snapping joint, machoire à ressort, or Kiefergelenkknacken, which names, however, denote only one of the symptoms. I have established (Foged 1941a, b, and c) that the cracking of the temporomandibular joint and accompanying clinical features are due to arthrosis—a degenerative non-infectious condition—and that the cracking (or snapping) is merely one of several symptoms in the more serious cases. In 1940 I suggested that the disease be called arthrosis temporomandibularis, which name covers its ætiology, pathogenesis, pathological anatomy, and symptoms. So far as I know, this name has not been criticised, and it has been adopted by Nørgaard (1947) and Boman (1947).

The lesion seems to have been described first by Sir Astley Cooper in 1823, and the first account of its surgical treatment was by Annandale (1887), who reported two successful cases of fixation of the meniscus. Much has been published on this subject since then, perhaps the most important being by Axhausen (1931), Boman (1947), Dufourmentel (1929), Konjetzny (1921, 1929), Posselt (1945), and von Stapelmohr (1929). The chief histological descriptions are those of Bauer (1932) and Steinhardt (1933, 1934); and Nørgaard (1947) has described temporomandibular arthrography.

MATERIAL

My material comprises 94 patients, with 138 instances of temporomandibular arthrosis, admitted to our department within the last nine years. These figures give an exaggerated impression of the frequency of the lesion, because most of the patients with temporomandibular arthrosis in this area are treated here or in the Rigshospital.

ÆTIOLOGY

Age and Sex

The lesion was found mostly in persons aged 20–30 years, and more often in women than in men. The distribution was as follows:

Age (years)	*No. of patients*	*Bilateral lesion*
<10	0	0
10–20	20	9
20–30	39	20
30–40	14	6
40–50	10	3
50–60	5	3
60–70	4	1
70–80	2	2
Total	94	44

Of these 94 patients, 17 were male and 77 female.

Duration

The disease is usually a protracted and chronic one. In 42 cases the onset was 2–14 years before admission: in 126 cases the duration was as follows:

Duration (years)	*No. of cases*
<$^1/_2$	37
$^1/_2$–1	20
1–2	27
2–3	12
3–4	8
4–5	5
5–10	7
10–14	10
Total	126

The ætiological factors are direct or indirect mechanical injuries. The direct injuries are acute mechanical trauma, such as a blow on the temporomandibular joint or on the mandible. The indirect injuries are repeated or chronic, such as protracted or forced yawning, subluxations and luxations, displacement of the bite (dental or prosthetic), dysfunction and hyperfunction (e.g., grinding and clenching of the teeth, and habitual or occupational strain on the teeth), disorders of articulation (e.g., obstruction to gliding movements, locked articulation, cross-bite, and forced bite), and unilateral function with either normal or reduced height of the bite.

It will be seen that the pathogenesis is analogous to that of corresponding forms of arthrosis in other joints. Dysfunction is most often due to anomalies of dental apposition and bite, the effect of which on the joint is transmitted partly during mastication and partly through habitual or nervous hyperfunction of the jaws—e.g., gritting of the teeth, and habitual firm clenching of the jaws (Posselt 1945).

CLINICAL PICTURE

Symptoms

The symptoms, and the number of cases in which they were noted as being present or absent, were as follows:

Symptoms	*Present*	*Absent*
Pain	113	25
Reduction of mobility	87	49
Locked articulation	29	106
Difficulty in mastication	115	22
Cracking, grinding, &c.	113	25

As a rule the patient first notes an oft repeated, but otherwise asymptomatic, cracking in the temporomandibular joint; sooner or later this is followed by pain on movement at the joint, especially on mastication. Gradually the pain becomes worse and is accompanied by reduction of mobility, which at first is usually insignificant, though worse in the morning, when it is difficult to move the joint. Later, the maximal opening of the mouth is reduced, and it becomes increasingly difficult to separate the teeth, with the result that finally the patient can hardly take any solid food, and he tends to become weak and emaciated.

Remote symptoms, which are emphasised especially in the American dental journals, have not been prominent in my material. This may, however, be because it was only after the end of the war, when foreign journals again become accessible to us here in Denmark, that my attention was attracted to such symptoms. The main ones are: headache, migraine, neuralgic pain, and abnormal sensations and disturbances of the ears, nose, mouth, and throat. In only a few of my cases has this multiform symptom complex been so pronounced that the patients complained of it of their own accord.

In some cases the lesion has spontaneously regressed or even disappeared either temporarily or permanently.

Signs

On physical examination a cracking in the joint was often heard. Inspection seldom revealed any abnormality. On palpation there was often tenderness on deep pressure and grating or cracking could be felt in most cases. Reduction of mobility on yawning, with lateral deviation or protrusion of the jaw, is one of the most important signs and was present in various degrees in the great majority of patients. Locking of the joint was observed only once.

* Read before members of the British Provincial Surgical Club on their visit to Copenhagen.

(*a*) those which provide convalescent treatment within the scope of the hospital service, and may therefore be appropriately used by regional-hospital boards; (*b*) those which provide recuperative facilities of the "holiday home" type, and may therefore be appropriately used by local health authorities; and (*c*) those which are a combination of (*a*) and (*b*). When this information has been obtained consideration will be given, on a national basis, in consultation with the two associations, to the question whether there should be any, and if so what, allocation of convalescent homes or beds between regional boards and local health authorities. For the purpose of the regional review, boards are asked to invite the council of the county or county borough in which each convalescent home is situated to nominate one or two representatives to join the board's officers in the survey of it.

University of London

At a recent examination for the diploma in psychological medicine the following were successful:

Eric Brenman, William Calder, D. H. Clark, J. A. Ewing, Joan I. Hallinan, Julius Hönig, Solomon Jacobson, J. M. Macdonald, J. H. McDougall, D. F. Macgregor, Secundus Mansvelt, J. D. Morrissey, Clement Rose, Lotte Rosenberg, I. M. Shepherd, Mohammad Shuaib, R. L. Sikes, R. J. Stanley.

Dr. A. C. Dornhorst has been appointed to the readership in medicine at St. Thomas's Hospital medical school, Dr. W. H. Hughes to the readership in bacteriology at St. Mary's Hospital medical school, Mr. Jack Joseph to the readership in anatomy at Guy's Hospital medical school, and Dr. R. B. Lucas to the readership in pathology at the Royal Dental Hospital. The title of reader in pharmacology and therapeutics has been conferred on Dr. C. A. Keele in respect of his post at the Middlesex Hospital medical school.

The following teachers have been granted recognition as teachers:

R. S. Lewis, oto-rhino-laryngology, Mary J. Wilmers, children's diseases, King's College Hospital; J. A. Hobson, mental diseases, Ian Jackson, obstetrics and gynæcology, Middlesex Hospital; Frances Gardner, medicine, Gladys Hill, obstetrics and gynæcology, George Qvist, surgery, Royal Free Hospital; A. G. Cross, [illegible] H. Morris, anæsthetics, St. Mary's Hospita[illegible] ntal surgery, J. W. Schofield, dental surgery, [illegible] Hospital; Gerald Garmany, mental diseases, [illegible] School.

The following have been granted probationary recognition for two years from October, 1949:

A. M. Horsnell, dental surgery, London Hospital; S. J. Holt, organic chemistry, J. B. Jepson, biochemistry, D. G. O'Sullivan, chemistry, Middlesex Hospital; A. G. Stansfield, pathology (morbid anatomy), Royal Free Hospital.

The John Marshall fellowship in surgical pathology, of the value of £700 a year tenable at University College Hospital medical school, has been awarded to Mr. B. B. Milstein, F.R.C.S.

Aureomycin and Chloromycetin Centres in Scotland

The Scottish regional hospital board centres for the distribution of 'Aureomycin' and 'Chloromycetin' are as follows:

Region	*Distribution centre*	*Tel. no.*
Northern	The Medical Superintendent, Raigmore Hospital, Inverness.	Inverness 681
North-Eastern	Dr. J. Smith, City Hospital, Aberdeen.	Aberdeen 2242
Eastern	Dr. W. Jamieson, King's Cross Hospital, Dundee.	Dundee 85211
South-Eastern	Tl[illegible]	Edinburgh 30271
Western	Tl[illegible] Glasgow.	Glasgow Central 9600

For the present the use of these drugs is restricted to certain conditions, which were listed in our issue of Nov. 19 (p. 955).

London County Medical Society

The annual general meeting of the society will be held at St. Giles' Hospital, Camberwell, S.E.5, on Wednesday, Jan. 4, at 3.15 P.M., when Dr. C. D. S. Agassiz will give an address.

U.S. Air Force Appointments

Major-General Harry G. Armstrong has succeeded Major-General Malcolm C. Grow as surgeon-general of the U.S. Air Force. Brigadier-General Dan Clark Ogle becomes deputy surgeon-general.

Poliomyelitis

During the week ended Dec. 10, notifications in England and Wales numbered: poliomyelitis 124, and polioencephalitis 10. In the previous week the totals were 141 and 15.

Royal Appointment

Dr. R. Bodley Scott has been appointed physician to His Majesty's Household in place of Dr. D. T. Davies, who was recently appointed physician to the King.

Presentation of Nobel Prize

In Oslo on Dec. 10 Lord Boyd-Orr, F.R.S., received the insignia and diploma of the Nobel peace prize. Afterwards he announced that he would use the award of £7815 to help in establishing in London a house where peace organisations could carry on their work.

Bulgaria Withdraws from W.H.O.

The government of Bulgaria has announced its withdrawal from the World Health Organisation. The U.S.S.R., Byelorussia, and the Ukraine withdrew last February. Up till now sixty-seven countries have ratified the W.H.O. constitution.

M.R.C. Staff Televised

Dr. P. L. Mollison, director of the blood-transfusion research unit of the Medical Research Council, and Dr. Margaret Mackay took part in a television programme on blood on Dec. 12. The programme included a short film sequence, taken for the broadcast by Dr. Brian Stanford, showing the use of fibrin foam in an operation for cerebral tumour.

Cryogenine, which was the subject of an article last week, by Geoffrey Bourne, is supplied as 'Cryogénine' (Lumière) by the Anglo-French Drug Co., Ltd., 11, Guilford Street, London, W.C.1.

Appointments

ALERGANT, C. D., M.B. Lpool, M.R.C.P.: consultant venereologist, Liverpool region.

BLACK, JAMES, M.D. Glasg., F.R.F.P.S., M.R.C.P.: medical director, no. 2 mobile mass-radiography unit, and asst. chest physician, Liverpool region.

DALZELL-WARD, A. J., M.R.C.S., D.P.H.: senior asst. M.O., public-health dept., Berkshire County Council.

MCCARTHY, MICHAEL, M.B. N.U.I.: deputy regional blood-transfusion officer, Liverpool.

Colonial Service:

BALLETTO, G. M., M.D. Genoa: M.O., Tanganyika.
CLARK, E. M., M.R.C.S., D.T.M. & H.: senior M.O., Kenya.
EDDY, T. P., B.A. Oxfd, M.R.C.S.: senior M.O., health, Sierra Leone.
GERBER, J. H., M.D. Berlin: M.O., Sierra Leone.
GOSCINSKI, ANTONI, M.D. Poznan: M.O., British Honduras.
GURD, C. H., M.B. Brist.: M.O., Nyasaland.
LANGWILL, A. M., M.B. Edin.: M.O., Nigeria.
MATHEWS, T. C. H., M.R.C.S.: M.O., Kenya.
QUIN, W. M., M.A., M.B. Edin., F.R.C.S.E., D.T.M. & H.: senior specialist, Sierra Leone.
SARKIES, J. W. R., M.R.C.S.: temporary ophthalmologist, Gold Coast.
SCOTT, D. B., M.B. Edin.: M.O., Gold Coast.
TILLMAN, JOHN, M.B. Edin., D.T.M. & H.: senior M.O., Nyasaland.

Births, Marriages, and Deaths

BIRTHS

CONWAY.—On Dec. 7, the wife of Dr. D. J. Conway—a daughter.

GARAI.—On Dec. 11, in London, the wife of Dr. Oliver Garai—a son.

IRVINE.—On Dec. 13, in London, the wife of Dr. R. E. Irvine—a daughter.

LEGGATT.—On Dec. 11, at Goring-by-Sea, the wife of Dr. H. D. Leggatt—a son.

READ.—On Dec. 12, in London, the wife of Dr. N. P. Read—a son.

RICHARDS.—On May 30, at Saskatoon, Saskatchewan, Canada, to Dr. Elizabeth Richards, wife of Dr. A. G. Richards—a son.

ROSS.—On Dec. 9, the wife of Dr. D. N. Ross—a daughter.

WOOD.—On Dec. 10, in Sheffield, the wife of Dr. Derek Wood—a daughter.

DEATHS

BRIERLEY.—On Dec. 8, at Ramsey, Isle of Man, Edward Edelsten Brierley, M.B., C.M. Edin., F.R.C.S.E., aged 77.

CAINE.—On Dec. 12, at New Ferry, Cheshire, Nathaniel Caine, M.D., C.M. Edin.

CHAMPION.—On Dec. 13, at Framfield, Sussex, Selwyn Gurne Champion, M.D., C.M. Edin.

ELLIOTT.—On Nov. 28, at Sea Point, Cape Town, Charles Caldwell Elliott, M.D. Lond., aged 83.

HIRD.—On Dec. 11, Alan James Hird, M.B., B.Sc. Glasg., M.R.C.P. [illegible]

MACKESSACK.—O[illegible] Peter MacKessack, D.S.O., M.B., [illegible]d, aged 77.

STEPHEN.—On D[illegible] George Stephen, M.B. Aberd., F.R.C.S.E., aged [illegible]

WEBB.—On Dec. 10, at Brighton, Frederick Henry Webb, M.B., B.Sc. Edin., aged 50.

lications

The only complication following surgery in our material was facial paralysis, which developed in 10 cases, but it was only partial and transient.

RESULTS

The results of surgery, as established by follow-up examination of 33 patients (41 cases), were as follows:

Good result	.. ..	32 cases
Improvement	.. ..	7 ,,
Unchanged	.. ..	2 ,,
Total	..	41

The follow-up period varied from six months to eight years; for 27 patients it was at least a year. "Good result" means that the patient is symptom-free, mobility of the jaw free, and mastication unhampered, though there may still be some cracking which does not inconvenience the patient. "Improvement" means that the patients are still not quite symptom-free.

The ability to open the mouth wider after the operation is illustrated in fig. 2.

Since the cases included here were severe, these results may be said to be satisfactory. Similar good results of surgery have been reported by Boman (1947) among others.

As a rule, the scar after the operation is visible but very small.

". . . If the world's governments will give one-hundredth part of the money they are using for war preparation to the specialised agencies of the United Nations, obstacles to peace will vanish. The United Nations is a better organisation than the old League of Nations, but its specialised agencies lack authority and funds. If the sixty governments which adhere to these would agree to devote to them one unit of their currency for every hundred they are devoting to preparation for war, and allow them freedom of action, I venture to predict that within a few years the political issues which divide nations would become meaningless and the obstacles to peace disappear. . . . The nation or group of nations which will make a great new gesture of friendship and an offer to collaborate with all governments in a simple and concrete world plan to development would win the allegiance of the people of all countries, who are sick to death of political conflict and preparation for war. The government which is strongest and surest of itself is the one which should take the lead in this road to peace. Any who refused to collaborate could be ostracised from the family of nations until they were willing to put the welfare of all before their own selfish interests. . . . Let there be less talk of war which inspires fear and panic and more talk of the great new age struggling to be born."—Lord BOYD-ORR, M.D., F.R.S., when receiving a Nobel peace prize in Oslo

A COMPARISON OF THE ANTI-THYROID ACTIVITY OF PARA-AMINOBENZOIC ACID AND THIOURACIL COMPOUNDS

J. F. GOODWIN
M.D. Lond., M.R.C.P.
RESEARCH FELLOW AND TUTOR IN THERAPEUTICS, UNIVERSITY OF SHEFFIELD

H. MILLER
M.A., Ph.D. Camb., F.Inst.P.
CHIEF PHYSICIST, SHEFFIELD NATIONAL CENTRE FOR RADIOTHERAPY

E. J. WAYNE
M.D., Ph.D., M.Sc. Leeds, F.R.C.P.
PROFESSOR OF PHARMACOLOGY AND THERAPEUTICS, UNIVERSITY OF SHEFFIELD

para-Aminobenzoic acid (P.A.B.) was first considered as a possible anti-thyroid agent soon after Mackenzie and Mackenzie (1943), Mackenzie (1947), and Astwood et al. (1943) had shown that it inhibited the function of the thyroid gland in rats. Gordon et al. (1945) showed that P.A.B. increased the weight and lowered the oxygen consumption of the thyroid gland in rats. Franklin et al. (1944), using surviving thyroid slices from sheep, demonstrated that P.A.B., thiourea, and thiouracil depressed the conversion of radioactive iodine to radio-thyroxine and radio-di-iodotyrosine at a concentration of 10^{-3}M.

Though the results of experiments on animals suggest that P.A.B. might prove effective in the treatment of thyrotoxicosis, only three reports of its use for this purpose in clinical practice have been published: Berman (1945) claimed good results in 6 cases treated by injection, and Popp (1947) gave P.A.B. by mouth with success in 4 patients, though Williams (1947) reduced the basal metabolic rate (B.M.R.) in only 2 out of 8 patients so treated.

PRESENT INVESTIGATION

A drug which would be as effective as the thiouracil group without displaying their toxic effects would be of great value. It was therefore decided to compare P.A.B. with thiouracil drugs in a few cases of thyrotoxicosis, and to use radioactive iodine to assess the relative efficacy of the two groups of drugs in normal people by the method of Stanley and Astwood (1947).

Preparation of P.A.B.—The sodium salt of *p*-aminobenzoic acid (Na P.A.B.) was prepared according to the following prescription:

Sodium hydroxide	..	40 g.
P.A.B.	..	137 g.
Essence of lemon	..	21 ml.
Chloroform water to	..	80 fl. oz.

This mixture, which is quite palatable, contains 1 g. of Na P.A.B. in each $^1/_2$ oz. dose.

Method.—Ten patients were treated with P.A.B. by mouth for periods varying from three weeks to nine months. All received 4 g. a day except case 6, who received 8 g. a day. All the patients, except case 5 who defaulted, were treated with thiouracil compounds (2 with propyl thiouracil and 7 with methyl thiouracil). The duration of thiouracil treatment varied from six weeks to two years except in case 9, who developed leucopenia after five days' treatment and cannot be considered a valid case for comparison. The dosage was that usually given for maintenance, but rather higher doses than usual were given to cases 1 and 3, who were resistant to the drug.

TOXIC EFFECTS OF P.A.B.

In the late war P.A.B. was used by Yeomans et al. (1944) in the treatment of typhus and was found to be safe in large doses for short periods (4–8 g. initially, A conspicuous and characteristic sign in the unilateral cases is deviation of the chin to the affected side when the patient opens his mouth wide (fig. 1). This sign was present in over half the cases. In about 20% of the cases the muscles of mastication were weak and atrophied on the affected side. The lesion is usually monarticular but may be bilateral. Bilateral lesions, however, seldom develop simultaneously and are rarely of equal severity. There is never any pyrexia.

In sum, the signs are similar to those of arthrosis of other joints.

Investigations

Radiography.—X-ray examination often revealed either structural or topographical pathological changes in the temporomandibular joint: deformities of the capitulum and articular tubercle; irregularities in the contours of the articular surfaces; narrowing of the joint gap; and a sclerotic subchondral marginal zone. This picture was often associated with reduced mobility of the capitulum on radiography during maximal opening of the mouth, and with upward and backward displacement of the capitulum. In many cases, however, the X-ray findings were normal. In many cases valuable information has been obtained from arthrography (Nørgaard 1947).

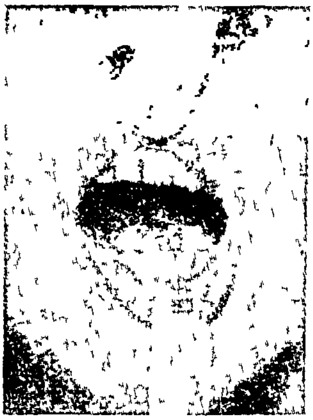

Fig. 1—Left temporomandibular arthrosis in a girl aged 18, showing reduction in maximal opening of mouth, and deviation of chin to left.

Blood Tests.—The Wassermann reaction and the gonococcal complement-fixation test were negative in practically all our cases, and the erythrocyte-sedimentation rate was nearly always normal.

Mastication.—I wish to emphasise the necessity of having the patients examined by a dental surgeon capable of assessing the masticating apparatus, discovering any dental factors which might favour the production of the temporomandibular arthrosis, and suggesting conservative methods for their elimination.

Analysis of Findings

The signs, and the number of cases in which they were found or not found, were as follows:

Findings	*Present*	*Absent*
Audible cracking .	51	83
Swelling, deformity	10	128
Tenderness . .	65	73
Intermediary cracking*	103	35
Terminal cracking*	17	120
Reduction of mobility	83	53
Deviation on yawning	69	64
Muscular atrophy .	27	111
Anomalous bite	111	18
Abnormal radiogram .	81	45

* "Intermediary" and "terminal" cracking occur when the mouth is partly and fully open respectively.

PATHOLOGY

The following changes were found at operation: (1) in many cases the meniscus showed evidence of altered mobility either in abnormal looseness or, more often, in too firm fixation to the capitulum by fibrous adhesions, (2) sometimes the lower joint cavity was more or less obliterated; and (3) the articular cartilage showed macroscopical and microscopical signs of degeneration, sometimes with deformity of the capitulum.

DIAGNOSIS

The symptoms are so characteristic that the correct diagnosis can hardly be missed. In the differential diagnosis only chronic monarticular arthritis may have to be considered, and here the X-ray findings, erythrocyte-sedimentation rate, and antistreptolysin titre will give significant information.

TREATMENT

Dental

Every case of temporomandibular arthrosis should be treated, even if the symptoms are only slight, in the hope of checking its progress. Primarily the treatment should be conservative, and here I strongly recommend measures which aim at restoring the bite to normal. This treatment is entirely dental and consists in prosthetic measures and adjustment of the height of the teeth, &c., to suit each case. Encouraging results have been obtained in our department (Posselt 1945), and similar good results have been published by Goodfriend (1932), Glahn (1932), Krogsgård (1944), Lindblom (1936, 1942), Boman et al (1943), and Miller (1943). This treatment is usually protracted and expensive, and months may elapse before it has any obvious effect. Diathermy, short-wave therapy, or radiotherapy sometimes produces temporary improvement. The pain may require analgesics for its relief.

Surgery

The following are the indications for surgery:

(1) Dental examination has revealed no cause that can be treated by a dental surgeon, or dental and other forms of conservative treatment have failed.

(2) The patient is unwilling or unable to await the outcome of conservative treatment or has no means or opportunity for such treatment.

(3) Progressive limitation of movement or frequent locking of the joint.

(4) The clinical condition, especially its duration, the severity of the symptoms, and the radiological findings suggest irreparable pathological changes in the joint.

Operation

The operation is always performed under local anæsthesia, either regional blocking of the mandibular nerve at the foramen ovale, or, more often, infiltration anæsthesia. I used to employ the preauricular incision of Schuckardt, but for most cases I now favour the Bockenheimer-Axhausen postauricular incision, which gives the surgeon a better view of the field. As a rule the operation consists of extirpation of the meniscus, together with severance of adhesions; sometimes only severance of adhesions is required but in a few cases resection of the capitulum has been necessary.

I have treated 36 patients by operation, in 8 of them the lesion was bilateral, making a total of 44 operations. The bilateral cases were always dealt with in two operations separated by a considerable interval of time

After-treatment

This is the simplest possible—fluid diet and prohibition of mastication for a couple of days, followed by active training of the movements of the lower jaw.

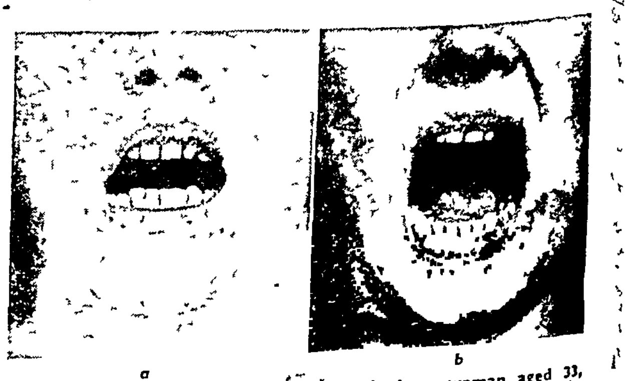

Fig. 2—Right temporomandibular arthrosis in a woman aged 33, showing maximal opening of mouth: a, before operation, b, six years after extirpation of meniscus.

In only 1 case was the response to methyl thiouracil smaller than in the two typical curves shown.

With P.A.B. the usual dose was 4 g. In general the effect of this dose was noticeable but less than that of methyl thiouracil, and did not seem to last so long. Fig. 2 gives three examples of curves obtained with P.A.B.: the uppermost is from a case where 4 g. of P.A.B. had no apparent effect; in the middle one some reduction in the rate of iodine retention is seen; and in the lowermost, with 6 g. of Na P.A.B., the take-up was completely suppressed after 72 minutes.

Most of the curves were of the form shown in the middle tracing of fig. 2, where there is a discontinuity in the straight line but where one can draw some kind of straight line through the experimental points after the break. The slope of the straight line obtained in these curves is, for a particular patient, proportional to the clearance-rate of the thyroid for the plasma-iodine. We have therefore tried to estimate the ratio of the clearance-rate before and after P.A.B. produces an effect. In 8 people given 4 g. of P.A.B. the clearance-rate with the drug was on the average half the clearance-rate without the drug. In 9 people given methyl thiouracil the clearance-rate was on the average reduced to 0·2 of the original clearance-rate.

These figures are approximate but suggest that 4 g. of Na P.A.B. produces a smaller anti-thyroid effect than does 200–300 mg. of methyl thiouracil.

Stanley and Astwood (1947) made a very comprehensive survey of some thirty-two anti-thyroid drugs, using 90 patients. They attempted a relative classification of those drugs by assigning them to one of five groups giving different degrees of inhibition, and by comparing the weights of drug necessary to give roughly the same degree of inhibition.

Our own results represent more tests for a given drug than were used by Stanley and Astwood. The curves of figs. 1 and 2 illustrate the wide range of effects produced by a given drug in the group of patients tested. We have therefore attempted a greater division of the observed degrees of effectiveness by assigning a number between 0 and 10 to each test according to the degree of effectiveness observed. For example, the group marked 0 shows complete absence of effect, group 6 shows suppression of take-up for the full time of the observation, and group 10 shows a substantial reduction in gland activity after the administration of the anti-thyroid drug.

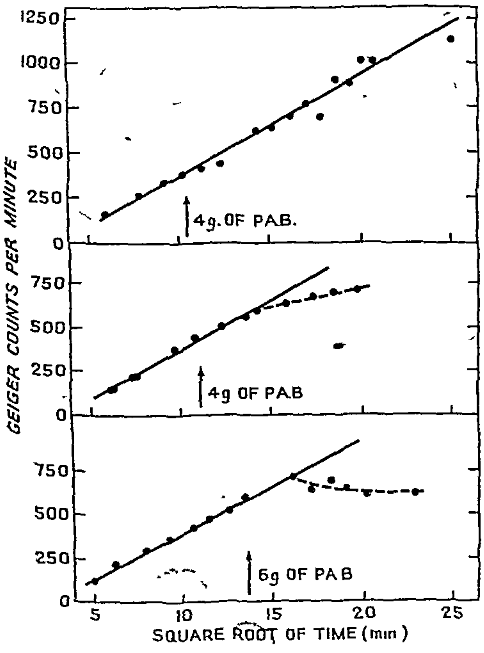

Fig. 2—Effect on accumulation gradient in thyroid gland of: (upper tracing) 4 g. of P.A.B.; (middle tracing) 4 g. of P.A.B. in another patient; and (bottom tracing) 6 g. of P.A.B.

COMPARISON OF POTENCY OF Na P.A.B. AND METHYL THIOURACIL

Drug	Dose	Degree of response										
		0	1	2	3	4	5	6	7	8	9	10
Methyl thiouracil	200 mg.	..	..	..	× ×	..	..	×	..	×	..	..
Methyl thiouracil	300 mg.	..	..	×	..	..	×	..	..	..	×	× ×
Na P.A.B...	4 g.	×	..	× × ×	×	×	..	..	×	..	..	..
Na P.A.B...	6 g.	..	..	..	..	..	..	..	×	..	..	..

Each × represents one subject tested.

In the accompanying table are set out the results of all the seventeen tests made, classified in this manner. This again illustrates our conclusion that 200–300 mg. of methyl thiouracil is substantially more effective than 4 g. of P.A.B. in depressing the iodine uptake of the gland.

CONCLUSIONS

The results of the clinical tests, and the evidence obtained by the tracer technique in normal persons, seem to show that P.A.B. has a definite anti-thyroid action, probably sufficient to influence mild or moderate degrees of thyrotoxicosis but significantly less than that of the thiouracil compounds. Patients with more severe grades of thyrotoxicosis are unlikely to be improved unless toxic doses are given. It should be remembered that methyl thiouracil has only one serious side-effect—agranulocytosis—whereas P.A.B. has at least three potentially serious side-effects—depression of the bone-marrow, renal damage, and fatty infiltration of the liver.

SUMMARY

The experimental and clinical evidence suggesting an anti-thyroid action of the sodium salt of *para*-aminobenzoic acid (Na P.A.B.) is briefly reviewed.

Thiouracil compounds were found to be more effective than P.A.B. in a clinical trial, though this showed that P.A.B. has some anti-thyroid action. Of 10 thyrotoxic patients treated with P.A.B. 6 did *not* respond at all, and in only 1 was full control obtained; there were no toxic effects. When 8 of these patients were treated with thiouracil compounds full control was obtained in 3, and only 2 did not show any response.

The technique described by Stanley and Astwood (1947) was used to compare the effectiveness of Na P.A.B. with that of methyl thiouracil in suppressing the uptake of radio-iodine into the thyroid glands of people with normal thyroid function. By this method a single dose of 200–300 mg. of methyl thiouracil was found to be substantially more effective in reducing iodine uptake than a single dose of 4 g. of Na P.A.B.

It is concluded that Na P.A.B. has a slight but definite anti-thyroid action in safe dosage (4 g. a day); but to obtain an action comparable to that of the thiouracil group toxic doses would be necessary. It is suitable only for the treatment of mild cases of thyrotoxicosis.

Thanks are due to Mr. G. Blomfield, F.R.C.S., for his cooperation; Miss L. Fearn for technical assistance with the Geiger-counter measurements; and Mr. J. Bowen for the construction of the counter housing and stand.

References at foot of next page

followed by 2 g. two-hourly). Depression of the bone-marrow and renal damage were thought to be possible complications. Zarafonetis et al. (1948) found that P.A.B. in high concentration inhibited all phases of granulocyte development in 10 cases of chronic myeloid leukæmia. Their patients received Na P.A.B. 2–4 g. two-hourly, and blood-P.A.B. levels were kept at 10–30 mg. per 100 ml. All the patients had glycosuria, and glucose-tolerance studies in 2 of them showed that their renal thresholds for glucose were lowered, suggesting that P.A.B. may interfere with renal phosphorylation. The same workers reported a death from toxic hepatitis in a boy of 4 years with subacute disseminated lupus erythematosus who was receiving 8 g. daily. May and Vallance-Owen (1948) treated 5 cases of myeloid leukæmia with P.A.B., and noted a profound fall in the total leucocyte-count and a tendency to hæmorrhage, the latter being attributed to leukæmic infiltration into the walls of small vessels, which were subsequently damaged by P.A.B.

Cruickshank (personal communication) has described the necropsy findings in 3 children treated with large doses of P.A.B. for acute rheumatism. Apart from the pathological changes due to acute rheumatism, gross fatty infiltration was found in the liver in each case. The treatment had lasted up to three weeks, and P.A.B. 1–3 g. had been given two-hourly, the blood-P.A.B. level occasionally rising above 45 mg. per 100 ml. The mode of death seems to have been what would be expected from acute rheumatism, but there seems to be little doubt that the fatty infiltrations were due to P.A.B., since identical changes were found in rabbits treated with large doses of P.A.B. by Cruickshank and Mitchell (1949).

In our cases no toxic effects were noted. In view of the higher dosage used in case 6, the bone-marrow was examined before and after treatment. Daily white-cell counts, alkali-reserve estimations, and examinations of urine were also done on this patient. No abnormality was detected in any of these tests during or at the end of treatment. It therefore seems that in moderate dosage (up to 8 g. a day) for short periods Na P.A.B. is safe, but that in larger doses it may be dangerous.

RESULTS OF CLINICAL TRIALS

In assessing the efficacy of the treatment four grades have been adopted:

O, no improvement.

+, slight improvement—i.e., slight general diminution of all toxic signs, or well-marked improvement in at least two signs.

++, great improvement in all signs and symptoms, but not complete control.

+++, complete control.

Subjective improvement alone has not been counted as evidence of any clinical control of the disease; the B.M.R. and the blood-cholesterol levels have been used as criteria in the assessment of results.

The results can be summarised as follows:

	Cases on Na P.A.B.	*Cases on thiouracil compound*
No improvement	6	2
Slight "	3	2
Great "	0	1
Full control	1	3
Total	10	8

It will be seen that, with P.A.B., slight improvement occurred in 3 patients, and complete control in only 1. The results with thiouracil were notably better—slight improvement in 2 patients, great improvement in 1, and full control in 3. Two patients were selected for P.A.B. therapy because of toxic reactions to thiouracil. Four patients seemed to be resistant to both groups of drugs: 1 of these had previously relapsed after thyroidectomy, and 1 subsequently relapsed after operation. In more than 100 cases treated with thiouracil and studied by us for from one to four years the incidence of complications necessitating the withdrawal of therapy was 12%, and 2% of the patients were resistant to the drug (Goodwin 1949).

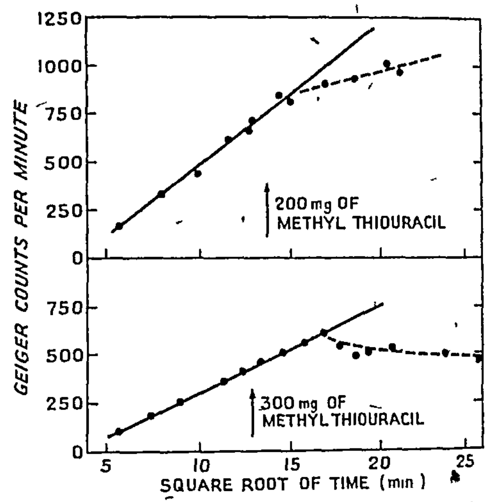

Fig. 1—Upper tracing shows effect on accumulation gradient in thyroid gland of 200 mg. of methyl thiouracil. Lower tracing shows alteration produced by 300 mg. of methyl thiouracil.

ASSESSMENT OF RELATIVE EFFICACY

After these clinical trials, radioactive iodine was used by the method of Stanley and Astwood (1947) to compare the effectiveness of Na P.A.B. and methyl thiouracil in normal people.

The technique is based on the fact that a dose of anti-thyroid drug, administered after a tracer dose of radioactive iodine and during the period when the active material is accumulating in the gland, produces a well-marked effect on the process of accumulation. This effect is an alteration in the shape of the standard build-up curve, and can readily be detected if the curve is plotted as a straight line. Over a limited time this can be done by plotting the activity in the gland against the square root of the time. A straight line results, since the early part of the curve during the build-up period is approximately parabolic. If the anti-thyroid drug is given during the period when a straight-line graph is expected, the effect on the iodine retention in the gland can readily be noted. This straight-line relationship holds for about 10 hours in normal persons, but for only about 3 hours in toxic cases. The latter are therefore unsuitable for this type of investigation.

By this method 19 people were tested. In 2 people the uptake was abnormal and no anti-thyroid drug was given; 1 of these was later found to have received a dose of an iodine compound about three days before the test. One group of people, who were tested with methyl thiouracil, received either 200 mg. or 300 mg. of the drug. It was evident that 200 mg. of methyl thiouracil produced a well-marked change in the capacity of the gland to take up I^{131}. It was in general, however, too small a dose to suppress the take-up entirely. With 300 mg. of methyl thiouracil a greater effect was generally obtained; indeed, some of the curves seem to indicate that there was a real regression of thyroid activity, involving a tipping out into the blood-stream of active iodine previously taken up into the thyroid tissue.

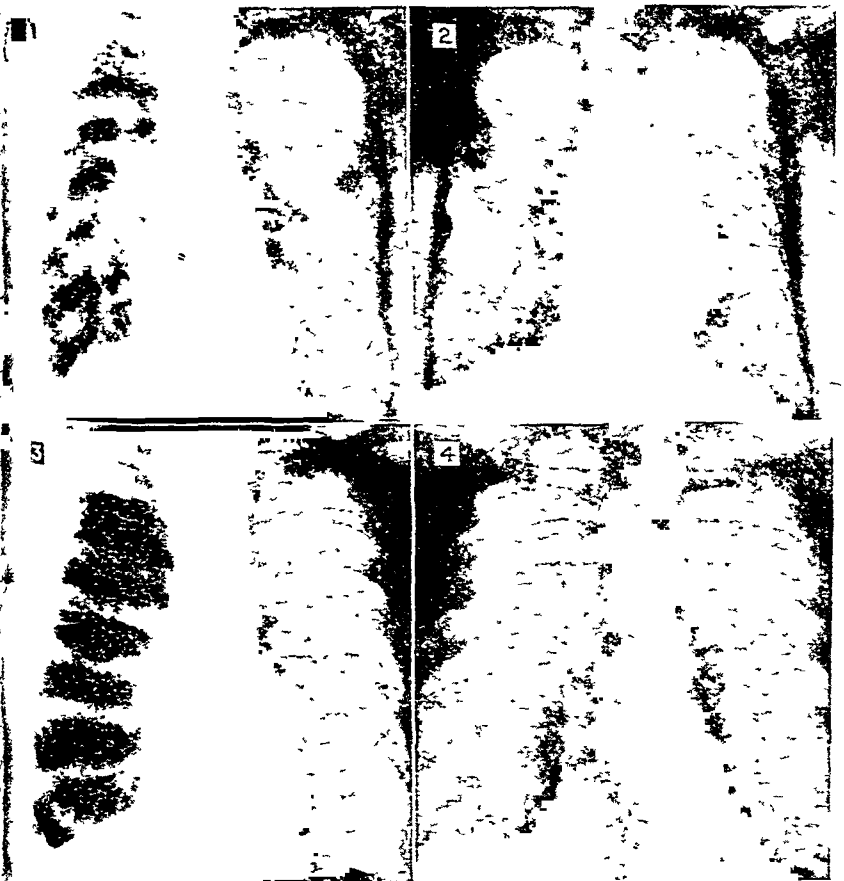
Fig. 1 shows two curves which are typical of the results obtained with methyl thiouracil, the upper one showing the effect of 200 mg., and the lower the effect of 300 mg.

With methyl thiouracil the effect of the suppression of the iodine uptake lasted as long as counting continued, generally about 6–8 hours after the drug had been given.

dust or fume inhalation, or of previous major illness. Thus the radiographic lesions are not attributable to residual changes following any specific illness or incident of which any of the workers were aware.

A sample of coke-flue dust obtained in the course of his work by a coke-oven worker was submitted to one of us (D. J. T. B.) for analysis. The dust had the appearance of burnt ash from coal; and the fine fraction, with a particle size of about 2 µ, was separated by means of a current of air. This fraction contained 34% of total silica, 2·6% of free silica, and 17·5% of iron compounds expressed as iron oxide (Fe_2O_3).

The fact that dust-products arising from the combustion of coke are siliceous is of primary importance. Similar pulmonary lesions have not been found by us, for instance, in ship's firemen who handle coal but whose work conditions resemble somewhat those prevalent among the present group. The possibility cannot be excluded that deposition in the lungs of iron oxides, which chemical analysis has shown to be present in the sample of coke-flue dust, may have caused some of the radiographic changes. These changes, however, do not resemble those of siderosis, reticulonodulation being less prominent than a patchy and rather coarse fibrosis.



Illustrative radiographs of the chest.

Case 1.—Aged 58 years, blacksmith for 36 years. Productive cough and dyspnœa for many years, gradually increasing. Right lung: fibrosis in upper zone, less in mid zone, nodulation in mid and lower zones. Left lung: miliary nodulation in lower zone, both hilar shadows accentuated

Case 2.—Aged 57 years, boiler-stoker for 23 years (working conditions reputedly bad) Cough with sputum and shortness of breath for 2 years; one small hæmoptysis Many fine râles heard in both lower zones posteriorly. Right lung: fibrosis in lower zone with several translucencies suggesting bronchiectasis, fibrosis in mid zone Left lung: fibrosis in lower zone adjacent to diaphragm

Case 3.—Aged 46 years, blacksmith for 30 years No symptoms; chest condition detected by mass radiography Right lung: slight fibrosis and translucencies in upper and lower zones. Left lung: clear, emphysematous

Case 4.—Aged 59 years, blacksmith for 46 years Shortness of breath gradually increasing for 4 years; productive cough for 3 weeks Clinically, bronchitis in both lower zones Right lung: well-marked striation and nodulation in mid and lower zones. Left lung: slight fibrosis in lower zone.

Most of the men admitted inhaling both gaseous and dusty products of burning coke, but a few claimed that little dust was inhaled. Thus the issue is raised of the relative importance of sulphur dioxide inhalation alone, and in combination with dust. It is not known whether chronic inhalation of small amounts of sulphur dioxide can cause pathological changes in the lungs that are demonstrable radiographically. Rambousec (1913) found, however, that traces of the gas acting over long periods set up inflammation of mucous membranes, bronchial catarrh, expectoration of blood, and inflammation of the lungs.

Johnstone (1941) listed the trades in which sulphur dioxide is used or in which there is risk of its being inhaled; these include foundry-workers, blast-furnace operators, and coke-oven workers. Accidental prolonged inhalation was followed by pulmonary œdema, respiratory paralysis, and asphyxia. He quoted Kehoe as reporting that chronic exposure produced upper-respiratory catarrh, anosmia, loss of sensation of taste, and increased fatigue; and other observers had noted in men exposed at work to the gas a lessened tendency to "colds" and bronchial and respiratory infections. Jacobs (1941) comments that sulphur dioxide readily evokes a defensive respiratory reflex in those unaccustomed to it, but that in time the amount necessary to produce an equal defensive response increases, indicating that tolerance may be acquired to its inhalation in small amounts. He fixed the maximum concentration that can be inspired for several hours without serious symptoms as 10 parts per 1,000,000. Durrans (1948) observed that workmen in a chemical factory exposed to an atmosphere "heavily charged with SO_2" remained remarkably free from "colds"—a fact attributed by him to the antiseptic qualities of the gas. Neither in these nor in other references to the results of sulphur dioxide inhalation is there any mention of chest radiographic findings.

Our tentative conclusion is that the series exhibits occupational pulmonary disease in men exposed to "sulphur" fumes and dust from coke-fires. Individual susceptibility may be a factor in determining the extent of the disease or disability, and the relative importance in causation of each product of combustion, solid or gaseous, is still undecided. The chemical composition of coke-flue dust could in itself account for the X-ray appearances that have been demonstrated. The patchy distribution of the X-ray changes is more readily explicable if we assume that protracted exposure to sulphur dioxide has caused localised chronic inflammation in the lungs, and that dust has later accumulated in these affected areas.

Further examinations of workers in these and allied trades are needed, irrespective of the

THERE are two aids to the detection of new types of pneumoconiosis:

(1) The patient's history. In areas with trades known to expose workers to the hazard of industrial chest disease, the physician will inquire into past dusty occupations and present work. In other areas, however, where the risk is smaller or is unrecognised, inquiry may be more perfunctory and thus an important clue remain undiscovered. In a centre where industry is various and much of it semi-skilled, workers will commonly have changed jobs once or oftener.

(2) The recognition among groups of workers of similar chest radiographic findings suggesting occupational disease. Retrospective inquiry may then discover some common factor, or factors, in past or present work conditions. The X-ray abnormality is one or more of the following:

(*a*) Fibrotic lesions that are non-tuberculous and are not attributable to, or not obviously the relic of, previous acute chest illness (e.g., pneumonia or abscess).

(*b*) Generalised miliary nodulation or nodulation mainly localised to mid and lower zones of one or both lungs.

(*c*) Chronic infiltration of bronchopneumonic type without any specific bacteriological findings in the sputum.

In pneumoconiosis lesions seen radiographically are usually bilateral; but they are not necessarily distributed symmetrically, or evenly in the affected area of lung.

Attention has been drawn to pneumoconiosis among boiler-scalers on the basis of common radiological findings and a history of inhalationary risk (Dunner 1943, Dunner and Hermon 1944). Chemical and pathological studies confirmed that siderosilicosis was present in the lungs of a boiler-scaler who died (Harding et al. 1944). Some of these patients, despite negative bacteriological findings, had been regarded up to then as cases of tuberculosis and even treated in a sanatorium.

Similarly, new types of pneumoconiosis have been detected in radiator and boiler finishers (Dunner et al. 1945), graphite-workers (Dunner 1945, 1948, Dunner and Bagnall 1946), and dockers handling grain and cotton seed, &c. (Dunner et al. 1946).

PNEUMOCONIOSIS IN STOKERS

Cases in the present series first attracted notice because of a similarity in chest radiographic findings which promoted a full inquiry into occupational history. The original case was in a man with radiological evidence of basal pulmonary fibrosis and bronchiectasis. Questioning revealed that he had been a "boiler-stoker" for 23 years, and that during his work in a confined space he inhaled "sulphur" fumes and quantities of dust, both originating from burning coke.

This case caused us to be on the alert for others, referred to the chest clinic, whose work exposed them to similar conditions. In this way a group of trades has been singled out which did not at first appear to have a common denominator of inhalationary risk. However, all the workers admitted that they had been exposed to irritant "sulphur" fumes and dust arising from coke-fires, in the course of working by open coke-fires or during intervals of hand-stoking. The trades represented in the series are boiler-stoker, blacksmith, plater, and employees in coke-oven and gas-works.

Gas-workers are subject to varying conditions, but a tour of a large efficient unit convinced us that no appreciable risk of inhaling sulphur dioxide exists, since, in the carbonisation of coal, air is excluded from the retorts. At the retorts workmen inhale briefly, but repeatedly, whiffs of crude coal-gas in a freely ventilated space. In this factory protective measures were enforced at all stages of gas-making. In the smaller and less efficient works protection may be less rigorously carried out by men and management, so that various gases and fumes or coke-flue dust may be inhaled.

Hitherto, 10 workers engaged in these trades have presented radiological signs of chronic pulmonary lesions. These 10 patients represent only a small proportion of the 50–60 such workers who have passed through the chest clinic since 1941. Thus not all the men exposed to risk develop radiographically demonstrable lesions. The radiographs of 4 men have been selected for reproduction.

All 10 patients in the series had respiratory symptoms, of which the chief were productive cough, exertional dyspnœa, and irritation of the nose and throat and sometimes of the conjunctivæ. As in pneumoconiosis generally, the severity and duration of symptoms bore no constant relation to the length of exposure or the extent of X-ray abnormality. Physical signs were by no means specific and did not conform with the abnormality later revealed by radiography. When present, sputum was repeatedly examined for tubercle bacilli, both by smears and by culture, with negative results.

The radiological appearances were those of irregular patchy fibrosis involving both lungs but usually predominant in one. In one case the right lung alone was affected, the left being emphysematous. In another the fibrosis was more diffuse, the upper zones being spared. In most the mid and lower zones showed nodulation which had occasionally produced, by confluence, patchy consolidation. Radiological evidence of emphysema was usually present, the radiotranslucent emphysematous zones being in sharp contrast with the adjacent areas of dense fibrosis. There were further signs of emphysema—flattening of the cupolæ of the diaphragm, and widening of the intercostal spaces and costophrenic angles.

In the differential diagnosis, tuberculosis was excluded with certainty. Pulmonary syphilis and Boeck's sarcoidosis were carefully considered and finally ruled out.

DISCUSSION

The association between radiographic pulmonary lesions of the type described here and a common risk of chronic inhalation of sulphur dioxide and dust, both arising from combustion of coke, is striking. It suggests a causal connexion between these occupational factors and the chronic pulmonary lesions found, which may be a type of pneumoconiosis hitherto unrecognised. In none of the workers was there any history of other risk of

ZINC-PROTAMINE INSULIN

1—A typical pattern from intracutaneous tests in a patient reacting cutaneously to insulin.

edles were used. Each reaction was read after minutes' interval and plotted.

RESULTS

The results showed that patients reacting cutaneously their routine therapeutic insulin irrespective of brand so reacted to the test insulin. In some patients there ere accessory factors, such as a moderate reaction to e buffer solution pH 3·0–3·2 or a fairly intense reaction salmine sulphate, a possible explanation of these ing that the solutions were non-isotonic. None of the sts gave such an intense reaction as those obtained with lutions containing insulin.

A typical pattern from intracutaneous testing is shown fig. 1. This pattern, however, is not invariable, ce fig. 2 shows a pattern from a patient who exhibited mild local reaction and yet did not respond to intrataneous injection of insulin. Only a few patients in e present series gave this pattern of reactions. Though l British commercial insulins are prepared from ystalline insulin, secondary protein (species protein) ay come over in the preparation and be included in the al product. The quantity of this secondary protein the final product may depend on the quality and ate of the raw pancreas or the care taken in the storage nd preparation of the insulin.

To test this hypothesis a solution of insulin recrystallised six times (supplied by Boots Pure Drug Co.) as prepared in the department of pharmacology of the niversity of Leeds, the final product having the me pH and antiseptic content as commercial soluble ulin. This was used on 34 diabetic patients who cted to various brands of insulin. The test site as the flexor surface of the forearm. The patients ere given 0·02 ml. of this solution intracutaneously nd also an injection of 0·02 ml. of insulin taken from eir current vial. The areas of reaction were compared fter 15 minutes, and the results were as follows :

	Mean area (sq. mm.)	*Difference*
Patients' current insulin	635·5	484·9 ±56·1
Insulin recrystallised six times ..	150·6	

he difference is strikingly significant.

Jorpes (1949) stated that about 300 patients in Sweden eceived recrystallised insulin because they had had ocal reactions with other kinds and most of them were eleved of the reactions. The results of the present nvestigation confirm Jorpes's findings and demonstrate r the first time the quantitative improvement attained th purified insulin.

In 2 patients the area of reaction to an intracutaneous injection of insulin recrystallised six times approximated to that caused by commercial insulin :

Solution injected	*Area of reaction (sq. mm.)* Case 1	Case 2
Patient's current insulin	320	664
Insulin recrystallised six times ..	375	587
Solution 2 (water adjusted to pH 3·0–3·2 plus 0·3% cresol) ..	62	82

It will be seen that neither cresol nor the pH of the solution was responsible for these reactions. Perhaps six crystallisations are insufficient to remove all traces of secondary protein, and perhaps these 2 patients were unduly sensitive. On the other hand, it is possible that they were sensitive to insulin protein itself. Without further evidence the correct explanation is not apparent.

DISCUSSION

In patients with severe local cutaneous reactions, especially of the generalised type, desensitisation has been attempted by Bryce (1933) and Corcoran (1938), and Weitz (1943) described a method of gradual desensitisation. These techniques are tedious to perform and are not uniformly successful. One patient remained free from allergic symptoms only for fifteen days (Bayer 1934).

In the milder reactions other methods of treatment have been described, such as changing the brand of insulin, and giving antihistamine drugs—e.g., 'Benadryl' (Leavitt and Gastineau 1947) or 'Anthisan' (Hunter and Hill 1947). Paley and Dews (1949), however, show no statistically significant reduction in the size of the cutaneous reactions when anthisan was used.

Diabetic patients troubled by cutaneous sensitisation to insulin may undergo spontaneous desensitisation and this fact invalidates many of the claims of successful therapy. Spontaneous cure has occurred in 30·5% of the present series.

It is therefore suggested that recrystallised insulin should be made available for the treatment of patients whose local reactions are sufficiently distressing. During this treatment spontaneous desensitisation may occur, and even if it does not, sensitivity may be sufficiently diminished for the patients to tolerate commercial insulin *once again*.

SUMMARY

The incidence of cutaneous reactions to insulin therapy in 147 patients attending the diabetic clinic at the General Infirmary, Leeds, in 1947–49 was 55·8% and was not confined to any one brand of insulin.

Most of the sensitive patients reacted to a test solution of commercial soluble insulin.

The importance of minor accessory irritative factors has been demonstrated, such as the pH of the solution and the salmine sulphate.

The mean area of reaction to an intracutaneous injection of the patients' current batch of insulin was 635·5 sq. mm., and with insulin recrystallised six times was 150·6 sq. mm. The difference is strikingly significant. This result confirms quantitatively the clinical findings of other workers.

It is postulated that some patients are sensitive to insulin protein itself. Alternatively, these patients may be sensitive to minute traces of secondary protein still lingering in the purified insulin.

Treatment of distressing local insulin reactions with recrystallised insulin is recommended.

I wish to thank Messrs. Boots Pure Drug Co. for supplying the recrystallised insulin and other test substances, and Mr. P. Hay, of the Department of Pharmacology, University of Leeds, for preparing the solutions.

presence of chest disability. Animal experiment may perhaps yield confirmatory results. Hitherto we have not had the opportunity to study affected lungs at autopsy, which might well provide conclusive evidence.

SUMMARY

Pneumoconiotic lesions not previously described have been found radiologically among workers in a group of trades involving exposure to sulphur dioxide fumes and dust from coke-fires.

Chemical analysis of a fraction of the dust with a particle size of about 2 μ has revealed siliceous and iron compounds.

MECHANISM OF CUTANEOUS REACTIONS TO INSULIN*

RONALD G. PALEY
M.D. Leeds
RESEARCH ASSISTANT, DEPARTMENT OF MEDICINE, UNIVERSITY OF LEEDS

DURING the early weeks of insulin therapy many diabetic patients are troubled with cutaneous reactions. This complication is rarely so severe that the insulin has to be stopped, but it is annoying and disturbs the patients when they are adjusting themselves to a new mode of life. Local sensitisation at the site of injection has been attributed to various factors. Banting et al. (1922) thought that protein impurities in their insulin preparation were the cause of induration of the subcutaneous tissues and an area of reddening of the skin surrounding the site of injection. With increased purification of the insulin a reduction in the incidence and severity of cutaneous reactions was reported.

When the long-acting protamine insulins were first introduced they were said not to produce cutaneous reactions, but Kern and Langner (1939) noted redness and swelling at the site of injection of protamine insulin. A similar claim was made for globin insulin by Bauman (1939), but other workers (Malins 1945, Paley 1948) have shown that it also can produce skin reactions.

In 1930, Campbell et al. showed that with crystalline insulin reactions were less severe than with commercial insulin. Allan and Scherer (1932) and Altshuler (1937) confirmed this work. Davidson (1934) and Corcoran (1938) reported single cases which gave positive reactions to intracutaneous injection of 0·1 ml. of crystalline insulin but did not indicate how many recrystallisations had been done on the insulins used. Hult and Jorpes (1949) reported a dramatic improvement following the use of recrystallised insulin instead of ordinary insulin in a sensitive patient.

Kern and Langner (1939) studied 104 diabetic patients, of whom 16% showed cutaneous reactions to protamine-zinc insulin. No positive test was noted in the whole group when injected intracutaneously with a protamine solution containing 0·1 mg. of nitrogen per ml. These workers concluded "that sensitivity to protamine could not be invoked as an explanation for the local re experienced by the 17 diabetic patients from inj of protamine-zinc insulin." Page and Bauman (1944) on the other hand, showed that protamine was in About 19% of their diabetic patients gave a reaction to intracutaneous injection of protamin solution. They also demonstrated the highly irritating effect of a zinc-chloride control solution. In the group of diabetic patients reactions to commercia beef insulin were five times as frequent as to purifie crystalline insulin.

INCIDENCE

Local skin sensitisation to insulin is undoubted common, but statistics of incidence vary great Lawrence (1925) stated that 30% of his patients had th complication, whereas Collens et al. (1934) found a incidence of 7·5%. Protamine-zinc insulin is reporte to give a higher incidence of cutaneous reactions soluble insulin. Nevertheless (see above) Kern an Langner (1939) reported an incidence of only 16% t protamine-zinc insulin. In the diabetic clinic of th General Infirmary at Leeds 55·8% of patients startin insulin therapy in 1947–49 developed cutaneous reactions Of the 147 cases studied, the reaction was mild in 81·7% (immediate in 74·4% and delayed in 7·3%) and severe i 18·3% (immediate in 17·1% and delayed in 1·2%).

The problem, therefore, is of practical as well a academic interest and merits a reinvestigation of th mechanism of these reactions.

METHOD

Diabetic patients reacting locally to their injection of insulin were submitted to a battery of intracutaneou tests as follows:

(1) Water adjusted to pH 3·0–3·2.

(2) Water adjusted to pH 3·0–3·2 with the addition o 0·3% cresol *B.P.*

(3) Ordinary soluble commercial insulin ('Regular,' wher insulin is in crystalline form), the pH and antiseptic conten of this solution being identical with test solution 2.

(4) Buffer solution with pH 7·0–7·2.

(5) Sterile 1% solution of salmine sulphate adjusted t pH 3·0–3·2.

(6) Commercial zinc-protamine insulin prepared from th same stock of insulin as test solution 3, the pH being the sam as in test solution 4 and the salmine content the same as i test solution 5.

Testing was done on the flexor surface of the forearm 0·02 ml. of each solution being injected intracutaneously Autoclaved all-glass tuberculin syringes with no. 2

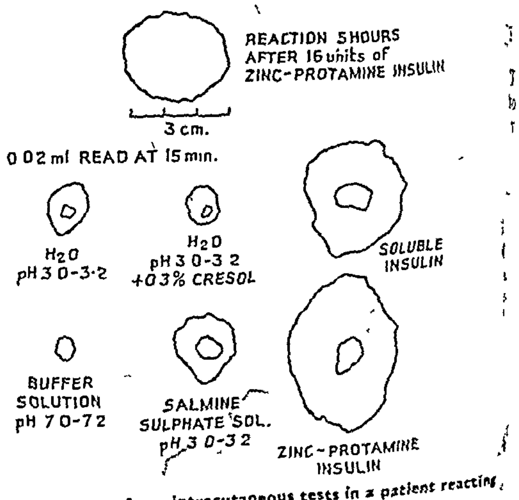

Fig. 1—Typical pattern from intracutaneous tests in a patient reacting cutaneously to insulin.

movement—e.g., in pressing down his car accelerator. looked well. and his legs. as before, had full power and muscle bulk; but there was general exaggeration leg tendon-jerks and bilateral ankle-clonus, which was d on the left. but not so on the right. The plantar were now indefinite but tended to be flexor, particu- on the right. In the arms there was no definite abnor- lity, but the tendon-jerks were all brisk and there was ble finger-flexion in the left arm. Sensitivity to cotton- was still diminished on the dorsa of both feet. especially left. Vibration sense was also slightly diminished at ankles, especially the left.

Aug. 31. 1948.—The patient was very well. "Jumpiness" the legs had now almost gone. A slight sensation of ness and swelling in the small toes of left foot was some- times noted at end of the day. There was hardly any weak- ness in the toes of the right foot; such as existed was more rked on dorsiflexion and in the small toes. There was very ghtly more weakness in the toes of the left foot, being a ttle less in the hallux than in the other toes. There was o other weakness. The tendon-jerks in the legs had increased, pecially in the left. Ill-sustained clonus could be elicited the left ankle. The tendon-jerks in the arms were brisk d normal. The plantar reflexes were flexor in the right and indefinite in the left. The abdominal reflexes were present, but the lower abdominal reflexes were diminished. sation was normal apart from moderate diminution of preciation of vibration, which was equal in both legs and ced at the ankles.

DISCUSSION

Gauthier (1913) pointed out that until 1874, when phoid paralyses were shown by Leydon to be due to ions of the nervous system, the view of Gruber (set in 1860) had been generally accepted—i.e., that weaknesses were due to the effects of typhoid fever the muscles. Since then, many types of nervous mplications have been described, and it is generally reed that myelitis is one of the least frequent of them. is certainly less common than typhoid polyneuritis, d even this is rare. as Wilson (1940) has pointed out, ing Rolleston's 12 examples among 3102 cases of typhoid ver. Similar figures were produced by Dufourt and oment (1934) in the Lyons epidemic, in which there re 10 cases of neuritic type among 3000 cases of phoid fever. But for many years it has been suggested at this extreme rarity of typhoid myelitis may be due incomplete examination of the nervous system or to masking of the signs by those of the general disorder. Bernheim (1895, 1912), examining a large number cases of typhoid fever from the end of the first ek of the illness and into convalescence, found at at any part of this period, and independently the severity, the tendon reflexes, particularly in legs, might become exaggerated. This was so 60% of his cases and was either transitory or lasted several weeks, and in these he felt that there was demyelinating lesion of the pyramidal tract. Rolleston 06) found alteration of the abdominal reflexes in out of 45 cases of typhoid fever; 34 of these showed mplete loss of abdominal reflexes and 4 had extensor ntar responses. Toomey (1934) described 19 cases of phoid fever which, over a period of just under three eks, showed in turn loss of abdominal responses, crease in knee-jerks, ankle-clonus, and extensor plantar sponses.

These cases of so-called myelitis "fruste" following phoid fever are probably much more common than the ree other clinical types of typhoid myelitis which ve been described: (1) "transverse" myelitis, in ich impairment of power and sensation lies pre- minantly below one level in the cord (Schiff 1900, pine 1903); (2) "ascending" myelitis (Landry's drome), which may develop very rapidly or by step-ladder" progress (Raymond 1885, Etienne 1899); d (3) "disseminated" myelitis. which may show more attered motor and sensory loss, and occasionally ataxia well (Marie 1884).

The prognosis of cases with general parenchymatous lesions varies greatly. Rapid death may ensue (Schiff 1900, Etienne 1899). or good recovery be made even from severe and extensive lesions of the spinal cord such as was described many times by Gauthier (1913). Renault and Levy (1913) in a child aged 4 years. and O'Brien (1944). The time in the course of the typhoid fever at which the myelitis appears does not seem to affect the prognosis. but it is evident that the chance of survival is better in limited myelitis than in one which rapidly becomes widespread. But prospects for full recovery are more difficult to assess at an early date, as can well be seen from the protracted history of our moderately affected case.

SUMMARY

A case of typhoid myelitis and neuritis of very protracted course is described.

The nervous symptoms came on at the end of the fifth week of a moderately severe attack of typhoid fever and resembled encephalitis; signs of neuritis and of a lesion of the spinal cord followed some weeks later.

Recovery, though very slow, has been continuous. but even after 5½ years is not yet quite complete.

The long period of healing suggests that there are permanent changes in the spinal cord. but, judged by present signs. these changes are surprisingly slight.

The progressive improvement seems to have been due to the recovery of demyelinated tracts, including the pyramidal. and to the clearing of an associated neuritis.

WE have shown (Spies and Stone 1949a) that in persons with nutritive failure and hypotension the administration of deoxycortone acetate produces an immediate increase in blood-pressure and body-weight (the increase in weight is associated with retention of sodium), and that the blood-pressure promptly falls when the deoxycortone acetate is discontinued (fig. 1). We have also been giving large injections of ascorbic acid intravenously to persons with rheumatoid arthritis without producing any demonstrable change in their condition (unpublished work).

It was decided to select patients with rheumatoid arthritis, restrict them to a diet low in sodium, and give them injections of deoxycortone acetate and ascorbic acid. The patients were restricted to a diet containing not more than 200 mg. of sodium daily. Each of the

PROTRACTED NERVOUS COMPLICATIONS OF TYPHOID FEVER

G. H. JENNINGS
M.A., M.D. Camb., F.R.C.P.
SENIOR PHYSICIAN, EDGWARE GENERAL HOSPITAL, MIDDLESEX

THE affinity of the typhoid toxin for all parts of the nervous system has long been recognised, and in describing the nervous complications of the Lyons epidemic of 1928 Dufourt and Froment (1934) pointed out once again that all parts of the cerebrum and cerebellum, mid-brain, medulla, spinal cord, meninges, nerve-roots, and peripheral nerves may be involved.

Outbreaks of enteric fever being uncommon in this country, descriptions of its neurological lesions are very infrequent in British publications. Rolleston (1906), in a study of the reflexes of 45 typhoid victims, noted the absence of abdominal reflexes in the majority, ankle-clonus in 15, and extensor plantar responses in 4. He concluded that the toxins of the typhoid infection were liable to produce " perturbation, however transient, of the pyramidal system." Against this brief record many reports of typhoid polyneuritis, meningitis, and myelitis, and accounts of cord compression by typhoid abscess are found in reports published in other parts of the world, particularly France and Latin America.

The following case, seen with typhoid fever 5½ years ago and since observed at intervals, is presented as an example of a probable moderate degree of typhoid myelitis. It also illustrates the fact that in the wake of typhoid fever neuritis may develop concurrently with myelitis and at first mask the signs of the lesion in the spinal cord.

CASE-RECORD

A male clerk, aged 31, was admitted on Jan. 16, 1943, with ten days' history of severe headache and two days' history of a swinging temperature. He had had anorexia, epistaxis, and diarrhœa (attributed to cascara) shortly before admission.

On admission he was thin and complained of general headache, malaise, and a feeling of abdominal distension. Temperature 103°F, pulse-rate 96. The patient was rational and alert. His tongue was furred and somewhat dry. There was no neck rigidity, and Kernig's sign was negative. The abdomen was soft and slightly distended. The spleen was not felt. There were no rose spots. The cerebrospinal fluid was clear, and contained no increase in protein or cells.

Progress.—The patient was constipated for the first two days in hospital, after which an enema produced a hard offensive stool showing no abnormal organisms. On Jan. 18 the first rose spots were noted, and these continued to appear for three days and then faded. The white-cell count was 6000 per c.mm. (polymorphs 76%, lymphocytes 21%, monocytes 2%, eosinophils 1%). On Jan. 21 the patient passed about 2 pints of blood per rectum and afterwards looked pinched and dehydrated. Up to this point the temperature had been 104°F with remissions. After the bleeding the pulse-rate rose to 140. One pint of blood followed by glucose saline was given intravenously, with considerable improvement. Constipation continued, but the [illegible] *became clear* and the abdomen was not distended. [illegible] were considerable *intermissions* in the fever, though up [illegible] Feb. 1 there were *occasional rises to 104°F. Constipation* persisted, and there was little appetite through most of February and the first half of March. During *this period* the temperature usually was between 100° and 103°F, with occasional *intermissions*. On Feb. 11 the patient [illegible] mentally confused and inclined to ramble. On the 22nd phlebitis developed in the left saphenous vein and spread up *into the* thigh, causing swelling of the whole of the left leg. This gradually settled, and it was then noted (early in March) *that there was general wasting of the legs* and considerable weakness in dorsiflexing both feet. The soles were hyperalgesic, and the appreciation of touch and vibration was diminished in the feet. All the tendon-jerks in the lower limbs were much depressed, and the calf muscles were tender. The patient got up on April 16, *having by then* been afebrile for a week after several further minor bouts of fever. *S. typhi*, which was first isolated from the stool on Feb. 1, persisted till Feb. 18, sulphaguanidine [illegible] *little effect. The Widal reaction* was positive up *to* 1 in 640 dilution on Feb. 18. The tendency to foot-drop, though decreasing, lasted until the patient was discharged on May 15, 1943, being moderate in the right foot and severe in the left, for which he needed a *toe-raising spring. On his* discharge the patient was taking a good diet with added vitamins—A, B_1, and D concentrates—and he continued to take these vitamins for many months.

Follow-up.—The patient was seen again on June 30, 1943, when he reported that in the six weeks since *discharge he had* gained over 1 stone in weight. He could walk quickly but *could not run, because of residual weakness in* the legs. On examination, he showed only very slight movements in the toes of the left foot, but those of the right foot were a little stronger. There was weak dorsiflexion of both feet, particularly *of the left foot. The knee movements* were good, and no wasting of the leg muscles was seen. There was no tenderness anywhere. The knee-jerks were very brisk, the ankle-jerks *absent, and the* arm-jerks brisk. The right *plantar reflex was definitely extensor*, but the left plantar reflex was unobtainable, because of the associated lower-motor-neurone lesion. There was, however, a bilateral leg-withdrawal response. The abdominal reflexes were all present. On the feet and round the ankles sensitivity to touch was diminished and the appreciation of pain blunted and delayed. Vibration sense was impaired in both feet, *particularly* the right.

On *Sept. 14, 1943, the patient had lost the* weakness of the legs and was in generally excellent condition, but dorsiflexion was very weak in both halluces, more so in the left than the right. The knee-jerks were exaggerated, especially on the right side; the right ankle-jerk was present, but that on the left was still absent. There were bilateral *extensor*-plantar responses, with leg withdrawal. The vibration sense was still impaired, especially in the *right foot. The impairment of* sensitivity to pinprick *now* covered a *sock-like* area, more *extensive in the right leg.*

Jan. 31, 1944.—The patient felt still further improved and could walk well and run a little. There was now a feeling of stiffness in flexion of the *halluces*, and on examination these movements proved to be a little weakened, especially in the left foot. Otherwise there were *normal* power and bulk in all leg and thigh muscles. Both knee-jerks were exaggerated, much on the left and *moderately on the right.* The right ankle-jerk was brisk, and the left ankle-jerk was *for the first time* definitely present. Both plantar reflexes were extensor, but all the abdominal responses were *brisk.* The arms showed normal *power* and coördination, and the arm-jerks were brisk. Sensation showed *persistent changes*; sensitivity to touch (cotton-wool) and pinprick was still diminished in both feet, more so *in the left* foot than in the right; vibration sense at the ankles was slightly diminished more so on the left side. *Joint* sense was *normal.* The cranial nerves were all normal.

Oct. 10, 1946.—The patient reported steady progress ever since his last visit nearly *three years previously,* but *had* noted a persistent slight stiffness in the toes and the development of a " jumpiness " in the feet, *especially* the left. During the previous year this *had become* apparent *as* an occasional

SUMMARY AND CONCLUSIONS

patients with moderately severe rheumatoid is were restricted to a low-sodium diet and given mg. of deoxycortone acetate intramuscularly and of ascorbic acid intravenously each day without any of symptoms. The ascorbic-acid injections were discontinued, but the injections of deoxycortone and the diet remained constant.

e days later three of the patients were given [illegible] ic hormone in divided doses without knowledge. The other three were given distilled at the same intervals and under the same circum[illegible]. The three receiving the A.C.T.H. had prompt Within eight hours they were improved, and improvement continued steadily during the three in which the injections were continued. The T.H. was then discontinued and these patients ptly relapsed.

This study was aided by grants from the Birmingham s Committee and from Hoffman La Roche Inc. The cortone acetate and A.C.T.H. were obtained through the rtesy of Dr. Kenneth W. Thompson, Organon Inc.; 'Lonalac' from Dr. Warren Cox, of Mead Johnson and ; and the ascorbic acid from Dr. Elmer Sevringhaus, of offman La Roche Inc.

SYPHILITIC BURSITIS

WITH REPORT OF A CASE

W. PROSSER THOMAS
M.A., M.D. Camb.

A. J. ROOK
M.A., M.B. Camb., M.R.C.P.

From the Skin Department, St. Helier Hospital, Carshalton, Surrey

Verneuil (1868, 1873), of France, is credited with the st accurate account of involvement of the bursæ d tendon-sheaths in syphilis. He recorded 4 cases of elling of the extensor tendon sheaths of the fingers in condary syphilis and later described gummatous bursitis. Moreau (1873), Chouet (1874), and Voisin (1875) made philitic bursitis the subject of their theses. Keyes 876), in America, published 5 of his own cases and ferred to 9 others in the literature, and several cases om other countries were recorded during the next few ars (Finger 1884, Buechler 1889). Churchman (1909) ported 1 personal case, analysed the 26 cases published to then, and gave a masterly review of the subject ich remains the best available.

Since Churchman's paper about 12 further cases have en recorded, mostly by Americans (Lane 1924, Coues 26, Garner and Schoch 1931, Swartz and Tolman 32, Epstein and Friedlander 1932, Morrissey and eynolds 1933, Milian 1933, Schrager 1944). Several these authors drew attention to the rather surprising sence of any published reports from the British Isles d to the fact that English writers on syphilis have her not referred to syphilitic bursitis or have given no tisfactory description of it.

CONGENITAL SYPHILITIC BURSITIS

Bursitis has only once been described in congenital philis—by Coues (1915), who reported an indolent ecranon bursitis in a boy aged 13. The bursa was ened and found to contain "gummy honey-like aterial." The blood Wassermann reaction was negative, t a radiogram of the legs showed tibial periostitis, d the response to specific treatment was prompt. Coues remarks that Clutton (1886), in his original account of symmetrical synovitis of the knees, did not mention the bursæ, and that there is no record of their involvement in other cases of synovitis.

BURSITIS IN ACQUIRED SYPHILIS

A simple serous bursitis and tenosynovitis can occur in the secondary stage of syphilis, but the symptoms are of short duration with or without treatment and cause so little disability that the condition is of minor importance. Though 9 of 26 cases collected by Churchman (1909) were of this type, all cases subsequently recorded have been in the tertiary stage.

Age.—If Coues's congenital case is excluded, the patients' ages have ranged from 41 to 68.

Sex.—Women are affected much more often than men.

The *duration of the syphilitic infection* has usually been unknown, but has been known to exceed twenty years.

The duration of the bursitis has been from a few days to fourteen years.

Bursæ Involved.—In most of the cases in women one or both prepatellar bursæ have been involved. In men the olecranon bursa has often been affected, but almost any bursa may be involved. Labarthé (1873) described involvement of an occupational bursa at the radial border of the right index finger in a joiner.

Influence of Trauma.—Trauma is undoubtedly of great importance in determining the localisation of syphilitic bursitis. Many of the women with prepatellar bursitis had been employed as cleaners, and other patients have given a definite history of an accidental injury which preceded the bursitis.

Clinical Features.—At an early stage the affected bursa is swollen, moderately tender, and fluctuant, but the overlying skin is unaltered. Later the swelling increases but becomes firmer and no longer fluctuant, and the surrounding tissues also become indurated. Subsequently the overlying skin shows a dull red discoloration and breaks down into punched-out ulcers, which tend to be grouped in the arcuate pattern typical of nodular ulcerative cutaneous syphilides. Eventually, if no treatment is given, a large fungating mass of gummatous tissue may develop. Symptoms are disproportionately mild. Spontaneous pain and tenderness on pressure are slight or moderate. There is little or no limitation of movement in the neighbouring joint and no radiological evidence of syphilitic involvement of the joint or bones. Tertiary cutaneous syphilides on the skin elsewhere have been present in several reported cases, but evidence of involvement of the cardiovascular system or of the nervous system has been exceptional. The blood Wasserman reaction is positive.

Pathology.—Material for histological examination has seldom been obtained. In Schrager's (1944) patient the changes were those of a simple gummatous inflammation.

Treatment.—The response to specific treatment has in most patients been dramatic, many cases resolving completely in 6–8 weeks.

CASE-RECORD

A married woman, aged 64, had been employed for the last seven years as a cleaner. Eight months before she attended the skin department she had felt slight pain in the left knee when kneeling at work. A soft swelling had then appeared over the knee-cap, and in a few weeks had become larger and harder and caused much discomfort on kneeling. After about two months the overlying skin had broken down into a few ulcers, which had discharged slightly, since when the condition had not changed. The patient had not had to give up work, because pain on kneeling had never been severe, and there had been no difficulty in bending the knee. She had had no spontaneous pain in the knee.

three meals was prepared and served under the supervision of Miss Jean Grant, nutritionist. Bread and butter without salt were used, and 'Lonalac,' a low-sodium milk powder, was given in an amount equivalent in protein value to a quart of whole milk. Each patient was allowed 60 g. of meat and one egg daily. The rest of the diet consisted of foods low in sodium content (Bills et al. 1949) in amounts sufficient to give a total of less than 200 mg. of sodium daily.

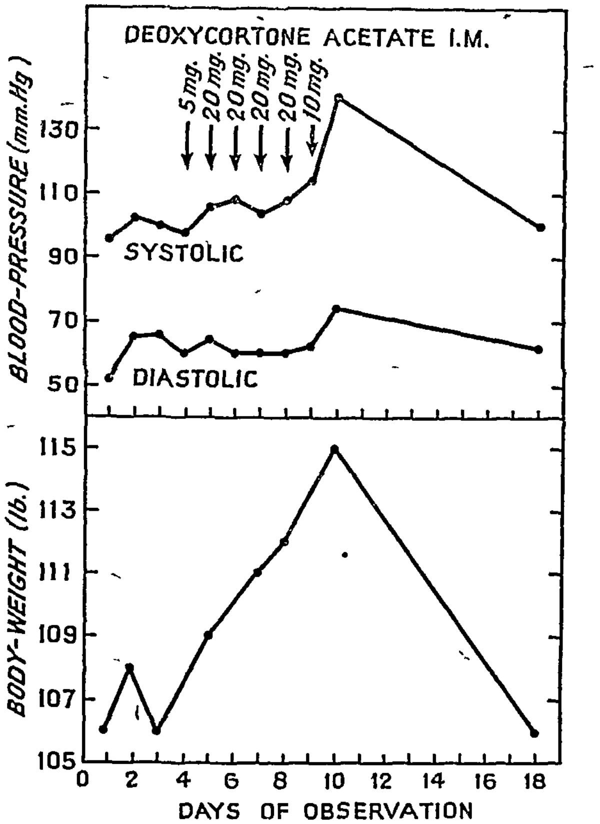

Fig. 1—Prompt increase in body-weight and blood-pressure under treatment with deoxycortone acetate.

To ensure that our patients were capable of responding we felt that we had to inject them with a compound which we knew could ameliorate the symptoms of rheumatoid arthritis. Hitherto we had tested A.C.T.H. on two patients with eosinophilia, who had responded to A.C.T.H., given in amounts of 25 mg., by a decrease of 50% or more in the circulating eosinophils. Thus A.C.T.H. had been shown to be potent in this manner (fig. 2).

Accordingly three men and three women, aged 31–64, were chosen. All of them had moderately severe rheumatoid arthritis and had had it for 2–10 years.

We had initiated this study but had not noted any relief from the combined injections of deoxycortone acetate and ascorbic acid when the preliminary communication by Lewin and Wassén (1949) appeared in THE LANCET. In this article they stated:

> "Five minutes after the injections the articular pain began to diminish and the articular mobility began to increase. Fifteen to thirty minutes later, the pain had practically disappeared and the mobility improved as much as the anatomical changes in the joints and muscular atrophy would allow. All the patients reacted in a similar way. In some cases the improvement was astounding. . . . The effect lasted from two to six hours, occasionally more than twenty-four hours."

We continued our studies for some days with their observations in mind, but we saw no amelioration of symptoms despite the fact that the ascorbic acid and deoxycortone acetate were injected almost simultaneously.

Without the patients knowing about it we divided them into two groups. Three of them were given injections of A.C.T.H. (8mg. four times a day); the other three were given injections of distilled water at the same times. Both groups remained on the diet, which was constant, and received the daily injections of deoxycortone acetate. By the time the injections of A.C.T.H. were started the patients were excreting little sodium in the urine. A representative study is shown in fig. 3.

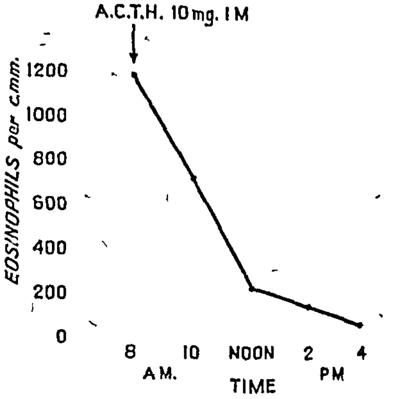

Fig. 2—Rapid decrease in eosinophilia after a injection of A.C.T.H.

The three patients receiving A.C.T.H. responded a has been described by Hench et al. (1949), Spies and Stone (1949b), Spies et al. (1949), and Markson (1949). They had an increased sense of well-being, they became less stiff, and the swelling and tenderness of the joints decreased. The patients could do things which previously they could not have done. One man, for example, who had previously had to be aided to get out of a wheelchair, could get out of the chair and walk to an automobile. After three days' therapy we were certain that the patients had responded clinically and we stopped giving the A.C.T.H. because of its scarcity. The tenderness, swelling, stiffness, and irritability returned within a few days. In a few more days the patients had relapsed almost to the condition in which they were at the start of treatment.

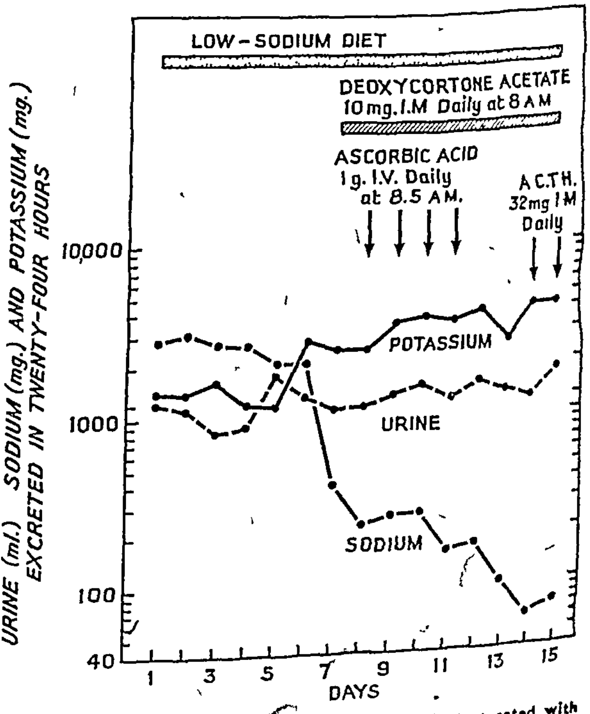

Fig. 3—A representative chart of one of the patients treated with injections of deoxycortone acetate and ascorbic acid, followed by injections of A.C.T.H.

; lumbar puncture usually revealed an increased content of the cerebrospinal fluid; and myelo- usually established the diagnosis. Other con- in the differential diagnosis were tuberculous metastatic carcinoma, and spondylolisthesis. 3% of operations no lesion was found. Naffzinger's and pain on lumbar pressure with the patient prone were important aids. Treatment followed the lines of bed rest, a plaster jacket for six weeks, and thereafter a corset, operation being reserved for cases which resisted treatment or recurred often. Manipulation was dangerous. Exploration must be extensive, including the 4th and 5th lumbar and the 1st sacral roots without laminectomy; both sides should be explored and the theca opened. Arthrodesis was usually performed only if relief was incomplete.

Mr. **Wardle** regarded retropulsion of a disc as secondary to loss of equilibrium of the whole spine and loss of elastic reaction in many discs. A plaster jacket, applied in head suspension, had given complete relief in 60% of patients. Mr. J. R. **Armstrong** detailed causes of operative failure: sometimes there was no lesion, or, more often, exposure was at the wrong level or a midline disc made disclosure difficult; a double lesion occurred in about 20% of cases; a bilateral lesion might need exposure on both sides; insufficient removal might allow further protrusion; a previously healthy disc might prolapse; a nerve-root might be damaged or might become adherent; there might be arthritis of intervertebral joints. Arthrodesis at the time of operation was unnecessary; it increased the complications and danger—and demanded more prolonged postoperative immobilisation. If required, arthrodesis could more conveniently be done later; it was difficult to repeat an operation on a root after an unsuccessful arthrodesis.

Mr. R. H. **Young** admitted an increasingly conservative approach. Mr. **William J. Virgin** (Liverpool) had studied deformation of vertebral discs under load and recovery on release. Performance, which improved with age and with successive loadings, did not appear to depend upon an intact nucleus, but upon the fluid content of the disc. Mr. G. L. **Alexander** (Bristol) stated that lumbar-disc protrusion might co-exist with spondylolisthesis, at the same or at a different level. Mr. **Nicoll** regarded myelography with the newer fluids as safe and helpful. Dr. E. J. **Crisp** had found that about 80% of patients were relieved by the application of a plaster-of-paris jacket without suspension. Mr. **Sayle Creer** (Manchester) advocated early operation, and Mr. **Philip Newman** emphasised the dangers of flexion in manipulation. Mr. A. D. **Le Vay** thought that clinical investigation was often neglected. Mr. K. H. **Pridie** (Bristol) ascribed the 20th-century tribulations of the low back to its want of one day's rest in seven.

Other Subjects

Protrusions of Cervical Discs.—Mr. **Alexander** referred first to nerve-root compression. He ascribed the frequent affection of the 6th and 7th cervical roots to their thickness; the 8th cervical root, also thick, escaped because its course was less oblique and it was less prone to stretching by cervical and shoulder movements. In cord compression, the symptoms and signs were often confused and lumbar puncture seldom helped, but myelography was helpful. Cord compression called for laminectomy and removal of the displaced material. Operative results were imperfect. Mr. **Barnes** advocated laminectomy in cases of injury of the cervical spine, with paraplegia but without bone displacement, if myelography revealed a protruded disc.

Lambotte and the Early Period of Bone Suture.—Prof. J. **Verbrugge** (Antwerp) painted a vivid picture of Monsieur Aloin Lambotte, an early pioneer of bone suture. At 85 this versatile and ingenious man still sometimes operated.

Fractures of the Upper End of the Radius in Children.—Mr. C. C. **Jeffrey** (Birmingham) confined himself to fractures through the neck of the radius and separations of the upper epiphysis. Most were abduction injuries, the position of the forearm determining the direction of the tilt, which could be estimated before reduction by radiography with the limb in various positions of rotation. Closed reduction was performed by digital pressure on the radial head in an appropriate position of rotation with adduction of the elbow. Late review showed good results provided that the radial head had not been completely displaced. Occasional premature fusion was much more pronounced if there had been complete separation, which led to deformity of the head and limitation of movement. Mr. R. C. **Murray** (Inverness) considered that open reduction was seldom needed. Mr. V. H. **Ellis** thought that limitation of rotation might be caused by subluxation of the lower radio-ulnar joint from disproportionate growth of the forearm bones after premature fusion of the upper radial epiphysis. Manual reduction of a greenstick fracture of the radial neck could not be maintained. Mr. **Scott** agreed that tilting of the radial head in young children needed no correction.

Experimental Rupture of the Medial Ligament of the Knee.—Mr. E. A. **Jack** (Edinburgh) had studied the results of experimental rupture in the cat. Ligamentous recoil always left a gap, which could no longer be closed after 7–10 days. Healing ensued except when the rupture was at the upper end. These experiments suggested that the ligament should be sutured during the first week, with the least possible damage to its blood-supply.

Hallux Rigidus.—Mr. A. C. **Bingold** (Leeds) showed how the basal epiphysis of the great toe might ossify from a dense or bipartite centre in the normal course of development, and he described the pathological changes in early and late hallux rigidus.

Osteotomy of the Spine.—Mr. W. A. **Law** showed a film of the operation and results of Smith-Petersen osteotomy in ankylosing spondylitis.

Experiences in Mauritius.—Mr. J. M. **Fitton** (Mauritius) described the island's peculiarities and the orthopædic service which had been developed since 1945, when an epidemic of poliomyelitis occurred. Mr. H. J. **Seddon** referred to the magnitude of Mr. Fitton's task and his modesty. Other Colonial orthopædic centres had now been established in Malta, Nairobi, and Lagos; and it was imperative that the men who built these up should find places on their return home.

Radiology and Histopathology of Malignant Bone Tumours.—Dr. A. L. **Taylor** and Dr. P. H. **Beamish** (Bristol) summarised the records of the bone-tumour registry at Bristol Royal Infirmary. The 72 primary bone tumours which had been recorded were classified as: (1) related to bone tissue, (*a*) osteogenic sarcoma, (*b*) chondrosarcoma, (*c*) fibrosarcoma; and (2) arising within the marrow cavity, (*a*) Ewing's tumour, (*b*) reticulosarcoma, and (*c*) multiple myeloma. Dr. R. C. **Tudway** (Bristol) pleaded for the treatment of osteogenic sarcoma by deep X-ray therapy alone. Mr. **Barnes** and Mr. H. E. **Harding** agreed about the value and safety of biopsy. Mr. K. I. **Nissen** spoke of the importance of the patient's age in diagnosis: Ewing's tumour seldom occurred after the age of 17 years, and osteoclastoma rarely before 20.

Posterior Scapulo-humeral Arthrodesis.—Mr. **Brittain** reported that bony fusion had taken place in 24 out of 30 patients operated on by himself and others.

Pregnancy and Skeletal Tuberculosis.—Mr. M. C. **Wilkinson** (Black Notley) described the effects of pregnancy in 32 cases of skeletal tuberculosis; in none had harm ensued. Mr. E. G. **St. Clair Strange** (Canterbury) confirmed this in 27 cases of sacro-iliac tuberculosis.

Excision of the Carpal Scaphoid Bone.—Mr. F. C. **Dwyer** (Liverpool) had found generally satisfactory results from complete excision of the carpal scaphoid bone in 19 patients with symptoms from ununited fracture. Mr. **Nicoll** considered that ununited scaphoid fractures called for no treatment if symptomless, excision if there were pain and only local arthritis, and arthrodesis if there was severe arthritis.

Arthroplasty of the Hip-joint.—Mr. **Charles Gray** demonstrated a film of cup arthroplasty of the hip through a lateral approach with removal of the great trochanter. Mr. **Pridie** preferred an anterolateral approach.

The patient said that she had always been healthy. She had never had a miscarriage, and could not recall any skin eruptions. Her first husband, by whom she had had three children now aged 29, 26, and 19 and in good health, had committed suicide seventeen years ago. Her second husband, by whom she had one child now aged 11 and also healthy, was alive and well.

On examination there was an indurated swelling $2^{1}/_{2}$ in. in diameter in front of and adherent to the left patella. The skin overlying the indurated area and extending downwards over the ligamentum patellæ was infiltrated and dusky red. There were three or four small punched-out ulcers and the scars of healed ulcers in this area. There was no local tenderness. Movements of the knee were full and painless. There was no clinical or radiological evidence of syphilitic involvement of the cardiovascular system or of the nervous system. The blood Wassermann reaction was strongly positive.

Radiological Examination (Dr. J. Lavelle).—There was no radiological evidence of osteitis or of periostitis. The tibia, fibula, and lower end of the femur were normal. There was a mild marginal hyperostosis of both patellæ, both femora, and both tibiæ—degenerative changes not excessive for the patient's age. The prepatellar bursa on the left side was swollen.

Progress.—The lesion regressed satisfactorily under treatment with bismuth injections and systemic penicillin.

COMMENT

The fact that only about 40 cases of syphilitic bursitis or tenosynovitis have been recorded probably gives a false impression of the rarity of the condition. Three of the authors who became interested were able to collect several personal cases in the course of a few years (Keyes 4, Verneuil 7, Moreau 4). Thus it seems likely that the true nature of some cases of "chronic housemaid's knee" remains unsuspected. Many of the published cases had been so diagnosed and had been treated ineffectively for long periods, with occasional resort to surgical intervention with unfortunate results.

Medical Societies

BRITISH ORTHOPÆDIC ASSOCIATION

THE annual meeting of the British Orthopædic Association was held in Bristol from Oct. 13 to 15 under the presidency of Mr. S. A. S. MALKIN (Nottingham).

Relationship of Orthopædic Surgery and Traumatic Surgery

Mr. WILLIAM GISSANE (Birmingham) said that 80% of patients who attended the casualty departments did so because of accidents, and only 10% were referred to the medical or general surgical departments. The casualty department had often proved a barrier to prompt effective treatment, and control of this department might justly be claimed as an orthopædic commitment. Fractures provided but a small part of the work of accident services. Accident hospitals like that at Birmingham could be developed for a population of about two million people, and both on economic and clinical grounds they should receive at once injuries of a specialised nature. An accident unit should retain and develop its relationship with surgery as a whole, and every accident hospital should be attached to a teaching hospital. After preliminary experience in general surgery and full training in orthopædic surgery, intending traumatic specialists should acquire at least the first principles of plastic surgery and thereafter gain practical knowledge of the work of a special accident unit.

Mr. E. A. NICOLL (Mansfield) said that traumatology was now practised in three ways: in conjunction with orthopædics; as part of general surgery; and as a specialty in its own right—though this was hardly yet justified, and in any event practice of such a specialty called for an orthopædic training. Better distribution of orthopædic surgeons was required. Mr. H. OSMOND-CLARKE suggested that accident units should usually be situated in general hospitals, closely associated with teaching hospitals. Whether the surgeon confined himself to traumatic work or not, training in general and orthopædic surgery was indispensable. Mr. RAINSFORD MOWLEM emphasised the importance of full coöperation in any traumatic unit between plastic and orthopædic surgeons. Mr. PHILIP WILES wondered whether the training of orthopædic surgeons would not be better organised with a university degree in the offing. Mr. R. H. METCALFE referred to one Metropolitan region in which registrars had been enabled to gain a varied experience by rotation through appointments in casualty departments, wards, consultative outpatient departments, and long-stay orthopædic hospitals. Mr. BRYAN MCFARLAND (Liverpool) held that an accident unit should be within a general hospital, with an orthopædic surgeon in charge, a plastic surg[illegible] treatment of injuries and in the [illegible] specialists. Mr. H. A. BRITTAIN [illegible] a certifying board appointed by the association, like the American Board of Orthopedic Studies.

Mr. A. N. BIRKETT (Nottingham) believed that accident hospitals were impracticable in many places. Experience, he said, was more important than a certificate. Miss M. FORRESTER-BROWN (Bath) referred to the Ontario scheme of postal advice on radiographs. The PRESIDENT hoped that this expedient would not be adopted here. The general hospital, he said, was the place for accident units and the training of orthopædic surgeons. Mr. H. LANGSTON (Southampton) said that pending the formation of large accident units, Mr. Metcalfe's scheme for registrars was excellent. Mr. NORMAN ROBERTS (Liverpool) urged that the accident unit should be situated in the general hospital, and that the casualty department should be controlled by the accident service and directed by the orthopædic surgeon. Mr. J. C. SCOTT (Oxford) deplored the inadequate orthopædic training of many traumatic surgeons. Mr. E. N. WARDLE (Liverpool) regretted the frequent appointment of the most junior member of a general-hospital staff to the casualty or accident department. Mr. ROLAND BARNES (Glasgow) advocated an accident unit under the control of the orthopædic department in every teaching hospital, for the sake of training undergraduates. Prof. GEORGE PERKINS thought that it might be agreed that everyone practising orthopædic or traumatic surgery must be properly trained and that traumatology was not to be encouraged as a specialty. The PRESIDENT concurred with this view and that practical experience was more important than a special degree; emphasis should be on training in general orthopædic surgery; and thereafter there should be special training in the principles of plastic surgery and specialisation in traumatology.

Lesions of the Lumbar Intervertebral Disc

Mr. J. PENNYBACKER (Oxford), on the basis of 800 cases, drew attention to the importance of differentiating disc lesions from cases of neoplasm. The latter were often misleading in their symptomatology, but their neurological signs were usually progressive. With a new growth, radiographs would occasionally show scalloping of the vertebral bodies or increased width between the

'CAMPOLON'

CRUDE LIVER EXTRACT

POTENCY and reliability: these qualities are of primary importance in the choice of a preparation for the treatment of pernicious anæmia. None fills the specification more aptly than 'CAMPOLON,' the crude liver extract. Administration of this preparation is followed by a prompt and satisfying change in the blood picture, while the patient's general condition shows a parallel improvement. 'CAMPOLON' contains 2 U.S.P. units per ml.

'CAMPOLON' FORTE

A concentrated liver extract, is especially valuable in severe cases of pernicious anæmia and in those with neurological symptoms.

Packings:

'CAMPOLON' FORTE, 15 U.S.P./ml.
Ampoules of 3 and 15 x 1 ml.
Bottles of 10 ml.

'CAMPOLON,' 2 U.S.P./ml.
Ampoules of 5, 25 and 100 x 2 ml.
" " 3 and 15 x 5 ml.
Bottles of 10 ml.

AN ADJUVANT IN THE THERAPY OF INFERTILITY

Nutri-Sal

In the absence of organic deficiences or pathogenies, hostile genital secretions may apparently cause infertility merely through immobilization of sperm.

In these cases Nutri-Sal—a physiologic glucose douche powder—encourages a more favourable environment, and supplies metabolic stimulus for sperm motility.

Clinical tests have shown that in such cases, where pregnancy *can* occur, a pre-coital douche of Nutri-Sal will often promote fertility.

Reviews of Books

British Surgical Practice

Vol. VI. Editors: Sir ERNEST ROCK CARLING, F.R.C.S., F.R.C.P., consulting surgeon, Westminster Hospital; Sir JAMES PATERSON ROSS, M.S., F.R.C.S., director of surgical clinical unit, St. Bartholomew's Hospital, and professor of surgery in the University of London. London: Butterworth. 1949. Pp. 554. 60*s*.

THE first five volumes of this great work have already been reviewed in these columns. Volume VI covers the surgical alphabet from Malingering to Peritonitis, in 37 sections. The high standard of text and illustration is maintained. We have commented before on the way in which surgical lumber and folklore have been cleared out, and here the good work continues—e.g., with the omission of Loewe's mydriatic test in acute pancreatitis. It is impossible to do justice to the individual excellences of 37 authors, but Sir Stanford Cade and Mr. E. Stanley Lee on malignant disease of the mouth and pharynx, Mr. Ivor Lewis on cut throat, and Mr. P. R. Allison on the œsophagus are particularly good.

The Group Approach to Leadership-Testing

HENRY HARRIS, M.D. With a foreword by General Sir RONALD ADAM and a preface by Brigadier A. TORRIE, formerly Director of Army Psychiatry. London: Routledge & Kegan Paul. 1949. Pp. 288. 21*s*.

THIS is an unofficial account, based on long personal experience, of the procedures used by War Office selection boards. The author was, by general repute, highly adept in the techniques he describes. Unfortunately skill in the practice of a technique does not always make for clarity in its exposition, and Dr. Harris has not simplified his task by combining psychiatric jargon with a military system of abbreviations. We encounter in his pages such monsters as MATCOP (mature coöperative or objective personality) and IMAG (immature-aggressive personality) and we make our way through the "progressive revelation of personality from the UGD through the IS to the HPS." Nevertheless, those who are concerned to discover "what went on at WOSB" will find the procedures fully described here. Dr. Harris is at his best when what he is describing is most concrete, whether it be the various group situations which were contrived for officer selection, or the methods of Japanese wrestling, which analogy prompts him to consider; he is least at home in his introductory treatment of theory. The formidable task of validation is not seriously attempted (we learn from Sir Ronald Adam's foreword that it will be undertaken in a later, and official, account); and the chapter, by another author, on the validation of boards, observers, and selection procedures could probably have been omitted from the present work without detriment.

Bacteriological Technique

A Guide for Medical Laboratory Technicians. W. W. W. MCEWEN, A.I.M.L.T., F.R.M.S., chief technician, pathological laboratory, Neath General Hospital. Foreword by Sir ALEXANDER FLEMING, F.R.C.P., F.R.C.S., F.R.S. London: J. & A. Churchill. 1949. Pp. 293. 15*s*.

MUCH clinical laboratory work now devolves on technicians. Their duties are diverse and exacting and in the public interest they need to have a high level of competence. Certificates of proficiency in laboratory technique are granted by the Institute of Medical Laboratory Technology, which has also arranged for regular courses of instruction in many centres throughout the country. These courses have accentuated the need of textbooks written specially for technicians, and this book, based on 25 years' experience, is sure of a warm welcome. In 31 chapters it covers the whole field of bacteriological technology, dealing more fully with practical details than do books addressed to medical students.

The first 7 chapters deal with laboratory equipment and maintenance. The next 15 describe standard procedures, such as sterilisation, centrifuging, media-making, and filtration. The remaining chapters are mainly descriptions of the common routine examinations, including those of water, milk, stools, swabs, and sputa. The final chapter is a useful account of the microscope, by E. G. Knowles.

The book presupposes a good knowledge of chemistry physics and considerable practical experience of bacte logical technique; it also supports the view that bacte logical technicians must know something of bacteriol itself. The writing is in the main clear and simple, bu contaminated by laboratory jargon and faulty spelling; text of the second edition should be passed through a fi that will remove these impurities, and also the marks exclamation. The figures are numerous and good.

The best judges of the work will be technicians, the author is entitled to look to them for criticisms suggestions; but two general comments may be ventu here. There can be no doubt about the superio of binocular over monocular microscopes for regular prolonged work; it may be true, as stated in this bo that for critical work they are less good, but freed from eyestrain far outweighs this objection. A chap on histological technique is too sketchy to be of pract value, and is superfluous in view of the special bo on this subject.

La streptomycine et le "P.A.S." dans le traitement la tuberculose chez l'enfant

MAX-HENRI BÉGUIN, médecin-assistant à l'Hôpi Jenner, Berne. Basle: Karger. 1949. Pp. 96. Sw. fr.

PROGRESS is so swift in chemotherapy that publicati are soon out of date. A monograph on streptomyc published in November, 1949, and based largely reviews of the literature, is unlikely to be of great va if, as in this case, it covers only publications to beginning of 1948. Dr. Béguin gives a short histori account of the in-vitro and experimental results, a the distribution and administration of the drug. T clinical review deals with all forms of tuberculosis in child, and gives in detail some of his own results: cases of meningitis were treated, with 11 deaths; children with miliary tuberculosis (which in only 1 w acute) were treated with streptomycin, and 2 w streptomycin and P.A.S.; the period of observation w six months. He also reports 4 cases of primary infecti treated with streptomycin, and 8 with streptomycin a P.A.S., and concludes that the results were better wi combined treatment.

The Function of the Thyroid Gland (Oxford: *Blac* well Scientific Publications. 1949. Pp. 37. 5*s*.).—Prof. J. Means, of Harvard, is both learned and stimulating; prose is full of amiable idiosyncrasies and is always wor reading; and this is a good lecture, though not of course comprehensive work.

A Short History of Physiology (2nd ed. *London* Staples Press. 1949. Pp. 140. 10*s*. 6*d*.).—Prof. Kenneth Franklin has given us a second edition of his little book. some 130 pages he traces the story of 2000 years of progre with at least a bare mention of some 500 of those who hav most contributed to it. To those who are not already famili with the subject, information so condensed can hardly mal easy reading, but physiologists will appreciate the industr and accuracy with which he has fitted the disjointed piec into the mosaic of his little picture.

Discoverers for Medicine (New Haven: Yale Universit Press. London: Oxford University Press. 1949. Pp. 219. 18*s* —Many of the most valuable discoveries from which medici has benefited have been made by men outside the ranks the medical profession. Dr. William H. Woglom's summar of these shows how much indebted the profession has bee to those "amateur" scientists. Not easily, and by the tedio process of trial and error, often in its course resulting damaged health, if not actually loss of life itself, did the pioneers pave the way for those methods of diagnosis an treatment which are now a commonplace. Dr. Woglom arresting narrative, full of facts hitherto unknown to th ordinary reader—and indeed to many in the medical professio itself—is a record of human endeavour crowned by succes He tells, for example, of Stephen Hales, a clergyman, fro whose remarkable investigations into the mechanics of th circulation derived our knowledge of the blood-pressure, an of Johann Mendel's discoveries in the field of heredity—perhap the most fascinating story in the book.

THE LANCET

LONDON: SATURDAY, DEC. 31, 1949

Control of Tuberculosis

LULLED by a slightly falling death-rate, we are apt to forget that in England and Wales tuberculosis still carries off some 400 people a week. An epidemic which killed on such a scale would arouse intense anxiety, and the sense of resignation which prevents stronger action against this endemic disease is quite irrational. Admittedly the rise in annual notifications may be due to better case-finding; but ought we to tolerate a system under which the diagnosed cases do not get prompt treatment? The rate at which sanatorium waiting-lists are growing was illustrated by Dr. H. J. TRENCHARD[1] when he said that the number of those awaiting admission to chest hospitals in the North West Metropolitan region rose from 1250 at the end of 1948 to about 2000 last September. To reduce the harm done by such delay, the domiciliary treatment of tuberculosis has been developed in a wider and more ambitious way than was ever previously considered; and it has proved its worth. The range of home treatment now undertaken by chest-clinic physicians is considerable in some areas, and could probably be extended everywhere. Certainly it represents an advance on the practice of leaving the patient to wait at home untreated—often for months, sometimes for more than a year. But surely the right time for home treatment is not at the beginning but at the *end* of the therapeutic course. Present housing conditions often make the nursing of the infectious patient both difficult and dangerous,[2] and such a patient, left in contact with his family, can seldom be trusted until at least he has been trained in sanatorium routine. There is a place both for institutional and for domiciliary care of tuberculosis; but normally the former should precede the latter, in the interest both of the patient and of the community. As Dr. C. H. C. TOUSSAINT[3] says, "there can be no more effective preventive measure than the conversion of infectivity."

To use the existing sanatorium beds to the best purpose is a measure of economy; but the policy of immediate admission cannot in fact be brought into action unless more beds are provided—at least temporarily. It is true that improvement of domiciliary care permits a quicker turnover, and sanatorium physicians could improve the situation if, when home conditions are suitable, they would discharge patients earlier to the care of the clinics. But the modification of sanatorium practice, however desirable, would not suffice in present circumstances to bring tuberculosis under control. Waiting-lists cannot be overtaken, and a rational policy cannot be initiated, unless we deliberately devote to this disease some of the beds now reserved, or used, for other diseases. Is tuberculosis really receiving the share of our medical resources which it deserves as a disabling and destructive disease of *young people*? Far from it—this infection, which could be virtually eradicated from this country within a few years if we took enough trouble, is allowed to reproduce itself continuously because, for historical reasons, it has been assigned a relatively low medical priority. As Dr. TOUSSAINT says, it is appalling that sufferers from the disease which takes a greater toll than any other of our industrial population should be debarred from all but a few hospitals, and should be forced to wait months for admission. Anyone coming to this problem with fresh eyes and an unperverted sense of proportion would certainly demand that priority for tuberculosis should be raised, that waiting-lists should be abolished at once by admitting patients to infectious-diseases and general hospitals, and that the complementary domiciliary service should be developed and used for its proper purpose—as a means of giving efficient and economical care to patients who have been made non-infective.

Given the will, however, there are still difficulties to be faced; and the biggest is that this is a question not of beds merely, but of nurses. Many nurses have an objection to nursing tuberculosis, and it is not altogether ill founded. Dr. DONALD COURT[4] has collected evidence to show that nurses are probably more liable to contract tuberculosis than women in other professions; but tuberculous infection has not yet been admitted to be an occupational hazard of nursing, and no special financial provision is made for those who go down with it. Miss EILEEN ANDREWS,[5] who has followed the histories of 59 tuberculous nurses over six years, found that many of them suffered great financial hardship. It is customary to say that sanatorium nurses—being better trained in protective measures, and more closely watched for signs of infection—are less likely to acquire the disease than nurses in general hospitals, and this may well be true, though we know of no published evidence to that effect. The Prophit Tuberculosis Survey,[6] however, showed that nurses in general hospitals with tuberculosis wards are four times as liable to tuberculosis as women in the general population, and that nurses in general hospitals without such wards are twice as liable. Hence the policy of admitting tuberculous patients to general hospitals and infectious-disease hospitals should be introduced only after full discussion with the nursing profession. Moreover, supervision of the nurse's health should be raised in all hospitals to the level recommended by Dr. COURT, and the whole subject of risk should be openly aired, so that nurses know clearly what they are undertaking and what is being done to ensure their safety and (at the worst) their care if they fall ill. In addition, pending the controlled trials, which we all desire, on "persons not known to be exposed to special risk," such protection as B.C.G. vaccine may afford should be offered to Mantoux-negative nurses as a routine.

FOCUS ON SULPHADIAZINE

for

EFFECTIVENESS

LOW TOXICITY

BLOOD-LEVEL MAINTENANCE

EVIDENCE ACCUMULATED during recent years indicates that Sulphadiazine is probably the most highly esteemed sulphonamide throughout the world.

Its effectiveness against many bacteria, its low toxicity, and the ease with which blood-levels can be maintained following its use all establish a preference for Sulphadiazine.

The physician will find Sulphadiazine Lederle the dependable sulphonamide in the majority of the commoner bacterial infections.

Sulphadiazine Lederle is available in bottles of 100 and 1000 0.5 Gm scored tablets.

BRETTENHAM HOUSE, LANCASTER PLACE, LONDON, W C 2

missionary who arrived at Chesterfield 16 days re the first case there was recognised but who, far as could be ascertained, had never been ill. ugh differing widely in case-incidence and fatality- tes. the two outbreaks were alike in including no ses in children under 3 years old and no deaths children under 8 years. The 78 patients in the two tbreaks included 5 over 60 years of age and were out equally divided between the sexes. Multiple ses in families were common; 12 out of 25 families Chesterfield had more than one case. Clinically, th outbreaks were typical. Most of the cases began th a feverish phase lasting 2–3 days, accompanied headache, anorexia, vomiting, and occasionally arrhœa. After a few days of comparative well- ing, the patients who were to develop paralysis gan a second feverish phase with headache, followed muscular pain, weakness, and spasm. In nearly these cases the lower limbs were affected. Trunk ralysis was also common but the upper limbs ere not often involved; the left arm was affected ore than twice as many times as the right. Menin- al, bulbar, and cerebral involvement and cranial- rve palsies were not seen in these outbreaks, and e deaths were all due to an ascending paralysis fecting the respiratory muscles. Lumbar puncture as done on 12 of the patients, all during or after e second week: the cerebrospinal fluid showed the ual increase in protein, but the cell-counts were ostly raised less than usual and were unrelated to the degree of paralysis. Histological studies on necropsy material from two cases revealed the typical lesions of poliomyelitis in the cord, most marked in the lumbar region; and the diagnosis was confirmed by injection of infected material into monkeys.

Low temperatures are used to preserve viruses in the laboratory, so one might expect the poliomyelitis virus to survive 80° of frost; and these Canadian outbreaks prove that at least one strain can not only survive but spread in an Arctic winter. Unfortunately the outbreaks throw no immediate light on the puzzling winter recession of poliomyelitis in temperate regions. Studies of the virus content of sewage have shown that this recession does not consist merely in the disappearance of recognisable clinical cases but is associated with a striking reduction in the viruses excreted by the general population. The Eskimo outbreaks raise some ticklish questions. Why, for instance, when the general attack-rates were so high, did children under 3 years entirely escape? Does the preponderance of lower-limb paralysis indicate that the central nervous system was invaded by virus from the intestine? Why was paralysis much more common in the left arm than the right? Why, even in severe cases, was there no cerebral or midbrain involvement? The exceptional way of life and unusual racial characters of the Eskimo may suggest speculative answers to these questions; but, as in much else connected with poliomyelitis, hypothesis is easier than proof.

Annotations

STUDYING THE FORM

THIS week brings disappointment to practitioners who ve hoped that the findings of the Inter-Departmental mmittee on Medical Certificates would promise notable lief from clerical work. Perhaps the most important commendation in the committee's report, which is mmarised on another page, is that National Insurance rtificates should be used for more general purposes an at present; certificates for employers might, it is ggested, be obtainable through the local National surance office. Otherwise the committee confines elf largely to enunciating broad principles and to scribing the many certificates and forms which the ctor may have to complete. On some of its specific commendations action has already been taken. The ggested statutory limitation of the certificates which e practitioner must provide without charge to his ational Health Service patients is provided for in the nending Act which was passed this month: and in veral instances proposals for the prolongation of a rtificate's validity or for the acceptance of alternative idence have been adopted.

If the report proposes no great relief, it at least nderlines the complexity of the problem under review. he committee heard evidence from no fewer than venty-seven Government Departments; as the report ints out, only these Departments can judge whether particular form or a particular question is indispensable, nd reduction in their demands must depend largely on eir own good sense, perhaps aided by a permanent pert committee. Rationing accounts for some of the eavy burden; but the truth is that nowadays few ctivities, whether Governmental or not, can be conducted ithout repeated calls on the doctor for certificates of ckness or of fitness; and the committee's report shows at while the forms might sometimes be more simple nd uniform, very few can certainly be abolished. robably no other professional man spends so much me as the [illegible] cal practitioner in clerical work of this rt. Y [illegible] ofessional time on the present scale is not inevitable. It could, for example, be curtailed by the provision of clerical assistance. In this respect the Minister of Health now has a clear responsibility, for he should be interested not only in providing medical attention under the National Health Service Act but in providing enough medical attention. The first step is clearly for each Department, having examined the joint committee's report, to search its conscience. The next should be for the Ministry of Health to analyse the cost in money and the economy in professional time from a routine which relieves the doctor of the task of actually filling in the various certificates and forms. The place for such a survey is a health centre; yet, even now, there *are* no health centres.

THE BACTERIAL NUCLEUS

THE "practical" (or, more correctly, "medical") bacteriologist probably uses his microscope less and less. Colony form, biochemical activity, and such technical tricks enable him to identify this and that as the cause of disease; and his interest is directed—always provided they will grow on his culture media—to problems of parasitism rather than to the anatomy and physiology of the humbler members of the vegetable kingdom. But lately other bacteriologists, who, presumably to avoid confusion, now call themselves "microbiologists," have introduced or revived microscopical techniques to throw light on subjects which their colleagues have either taken for granted or ignored. Of these subjects few have received more attention than the existence of a nucleus in the bacterial cell, and the part that such a body plays in reproduction and, possibly, in the transmission of heritable factors. It may now be said that some bacteria, if not all, contain bodies with most of the characters of the nuclei of other cells, and the recent paper by Bisset[1] not only extends this claim to *Bact. coli*, but by argument and photographic illustration must go a long way to convince the doubters. The resting cell contains a "microcyst," within which is a nucleus. As vegetative growth proceeds this nucleus takes the form of several chromosome-like bodies, which, so long as active growth continues, multiply both

River Pollution

OUR highway law is still based upon a pre-Victorian statute of 1835; our public-health code, enacted in 1875, was not rewritten until 1936. Perhaps therefore it is not surprising that our present provisions for preventing the pollution of rivers were passed as long ago as 1876, or that the important report[1] of the rivers pollution prevention subcommittee of the Central Advisory Water Committee recommends that this old law should now be modernised and strengthened.

Much is hoped of the river boards recently established under the Act of 1948 on the admirable principle that every river (or, in some cases, groups of rivers) shall have a single administrative authority, based on catchment areas and not on local-government units, responsible for its condition from source to sea. One of the recommendations of the report is that effluents discharging into a stream or river should be made to comply with standards prescribed by these river boards. These standards would be stated in by-laws, subject to confirmation by the Minister of Health, under a procedure which would allow a prior hearing to interests likely to be affected. The standards would not be uniform but would vary from river to river. Under the Act of 1876, legal proceedings for pollution by trade and mining wastes are not to be taken unless the central department consents. The report advises that, once the standards have been prescribed in consultation with industrial and other interests, the Minister's consent should not be required before a prosecution is undertaken. Another recommendation is that river boards should have power to control new openings for the discharge of effluents into a stream or river, and that they should be given notice of proposed changes in existing discharges. The report suggests that by-laws might prescribe standards of temperature at which liquids may be permitted to enter a stream. An appendix gives details of the ascertained effect of discharging pure but heated water into streams already in some degree polluted. Organic matter so discharged in sewage effluents or in industrial wastes from dairies or beet-sugar factories undergoes oxidation at the expense of the oxygen dissolved in the water. The rate of oxidation rises with increase in temperature over the range ordinarily found in the river. Sometimes the water in a stream or estuary may be almost saturated with dissolved oxygen in the coldest months of winter and almost devoid of oxygen in the hottest part of summer. The temperature of a polluted stream is also of very great importance to its fish life.

It is true that the Act of 1876 is not the only source of law for checking river pollution. There was an amending Act in 1893. There are useful clauses in the Salmon and Freshwater Fisheries Act, 1923, to punish the intrusion of liquid or solid matter into water containing fish so as to make it poisonous or injurious to fish. There is section 259 of the Public Health Act, 1936, which directs local authorities to detect and deal with any watercourses so foul as to be prejudicial to health or a nuisance. There are anti-pollution provisions in the Water Act of 1945 and the Gas Act of 1948. More important still, many progressive municipalities and county councils have persuaded Parliament to allow them to advance ahead of the general law; their experimental legislation may well be ready for universal adoption. Somehow one gets the impression that there are too many enactments on the subject, perhaps also too many Ministers concerned, and also that the law has either timidly bought off opposition at the cost of sanctioning exemptions for trades and businesses and mines and railways, or else has expressed itself in terms so uncompromising that nobody cares for the adventure of enforcing it. The most promising aspect of the recent report is that the members of the subcommittee were drawn not only from the associations which represent local authorities, catchment boards, and fishery boards but also from the Federation of British Industries, and that their conclusions are unanimous. The organisations which contributed written or oral evidence included the National Coal Board, the British Electricity Authority, and bodies representing canals, field sports, landowners, launderers, and ramblers. All this amicable discussion may eventually yield better results than fresh statutory prohibitions.

Arctic Poliomyelitis

As everyone knew would happen, this year's high incidence of poliomyelitis—second only to that of 1947—has fallen with the coming of colder weather. And nobody has been surprised that the unusually prolonged summer was parallelled by an unusually protracted epidemic. For here, as in the U.S.A. and Australia, epidemic prevalences in the late summer and autumn months have always declined with the approach of winter. This seasonal rise and fall, so far unexplained but often thought to offer a possible clue to the mode of spread of epidemic poliomyelitis, is not universal. For instance, in Iceland, which at times is more severely affected by poliomyelitis than any other country in the world, the incidence has sometimes reached its maximum in the winter; and during the late war the serious epidemic in Malta began in November, 1942, and lasted until the following March. Even so, it was rather astonishing to hear[1] that two outbreaks occurred among isolated Eskimo communities in the Arctic regions of Canada during the winter of 1948–49, which was one of the coldest ever known

The affected communities live on the western coast of Hudson Bay or in its hinterland, between latitudes 60° and 65°N, which is as cold as any part of the Arctic mainland and feels colder because of constant winds. In this severe winter the temperature fell as low as —49°F—i e, 81° of frost. In the first outbreak, which affected a group of four trading-posts with a combined population of 500 Eskimos, between September, 1948, and March, 1949, there were 21 cases with paralysis and 4 deaths. In the second outbreak, at Chesterfield, a trading-post farther north, in February (the coldest month of the winter) there were 39 cases with paralysis and 14 deaths among a population of 275; including the non-paralytic cases the attack-rate was at least 50%. Poliomyelitis probably spread to the Eskimo communities involved in the first outbreak by ship from a military installation at Churchill a hundred miles or so to the south, where a case with paralysis occurred in July, 1948. The only known link between the first and the much more severe second outbreak was

Points of View

ARMY MEDICINE IN THE LATE WAR

SOME MISTAKES OF POLICY ?

JOHN W. TODD
M.D. Lond., M.R.C.P.
ASSISTANT PHYSICIAN TO FARNHAM HOSPITAL ; LATE LIEUT.-COLONEL, R.A.M.C., OFFICER IN CHARGE OF MEDICAL DIVISION

(Concluded from p. 1198)

4. Medical Classification and Disposal

WHEN studying a potential recruit, the obvious question : "Is this man likely to be useful to the Army in any which is at present short of personnel ?" But in the members of selection boards were not allowed ask this question. It was laid down that certain defects or diseases were an absolute bar to admission to the Army, irrespective of the individual's abilities. And large numbers of excellent men were kept out of the Army because of such findings as high blood-pressure, varicose veins, flat-feet, or missing fingers.

In my view even severely diseased or disabled men need not have been kept automatically out of the Army. If such men could do useful jobs in civil life. they could commonly do the same when soldiers. The widespread assumption that life in the Army is necessarily much harder than civil life and requires a higher standard of health is false.

For example, during the war the life of the average medical officer stationed at a military hospital in England or in base areas abroad was very easy. He was usually stationed in the country, and had little to fear from the bombs of the enemy ; his hours were often short and usually fairly regular ; he rarely left his bed at night except when orderly officer, perhaps once a week (and even then he was often left undisturbed) ; he had frequent leave ; he was untroubled by problems of rationing and provided with plentiful food ; and he was usually comfortably housed and given a batman to look after him. By contrast, his brother in general practice was nearly always overworked and had his nights constantly disturbed, if in a large town was often bombed, rarely if ever had a holiday, and in every way led a hard and difficult life.

Although medical officers were admittedly a privileged body, the same considerations apply, if in less degree, to the vast numbers of clerks, cooks, and technicians of all kinds needed in the modern Army, and also to many combatants, such as heavy anti-aircraft and Coast Defence gunners, and the great majority of the non-flying personnel of the R.A.F.

The following case illustrates what everyone knows—at least if the matter is not being considered from a "medical" standpoint—namely, that the psychological qualities are of overriding importance by comparison with the physical in determining a man's excellence as a soldier.

An officer who had served with distinction in the first world war lost an eye, sustaining such severe damage to the orbital bones that he was never able to wear a glass eye but had to use a shield instead, and leaving behind chronic osteitis necessitating numerous operations for the removal of sequestra. During that war he also developed two herniæ and a duodenal ulcer which was treated by gastro-enterostomy. As he continued to have severe ulcer symptoms, including several hæmatemeses, he was finally awarded, round about 1924, a 100% disability pension. When the second world war started he succeeded in getting himself into the Pioneer Corps without seeing a medical officer. He went to France but was taken prisoner during the German invasion. After a year in a prison camp he escaped with 15 men and succeeded in conducting them all to Gibraltar, the party negotiating the Pyrenees in mid-winter. For this feat he was awarded a bar to the Military Cross he had won in the first world war.

CATEGORISATION AND DISCHARGE DURING THE WAR

Soldiers were classified largely according to structural defects. It was not even left to the medical officer's or board's discretion to judge the significance of some defect in any particular case, for there were a number of cut and dried instructions on the matter. The man blind in one eye was automatically put in category B.3, which meant that he could never belong to any kind of fighting unit in the field. There were similar regulations in respect of such disorders as perforated ear-drums, flat-feet, and knock-knee, and in India a further series of regulations referred to enlarged spleens, stones in the urinary tract, and other conditions common in the tropics. When sitting on a medical board one used a form entitled "form for the medical recategorisation of a soldier." In fact, when dealing with a man affected by one of these conditions which had been the subject of a regulation, one was not allowed to recategorise *a soldier* ; all one could do was to recategorise a tympanic membrane, the first part of a duodenum, a spleen, a big toe, or the lens of an eye.

Naturally these regulations had absurd consequences.

In one unit to which I was attached we had nine R.I.A.S.C. drivers. All had perfect vision, excellent arches to their feet, hæmoglobins of 100%, two testicles in their scrotums, impalpable spleens, and mobile joints. Indeed, they had but one defect ; they were incapable of driving. Three smashed so much valuable Army transport that the C.O. permanently forbade them from driving any more, and another three were only allowed to go on specified easy journeys. But fortunately we had a nursing orderly in the unit who, though blind in one eye (and therefore "unfit" to drive), was a superb driver, his peace-time job consisting in driving lorries through the Highlands of Scotland. He was therefore given a stripe and put in charge of the unit's transport.

An ex-Territorial warrant officer had had a perforated ear-drum for many years. During the first four years of the war this lesion was fortunately overlooked, and it never caused him any trouble. As the result of a slight and transient aural discharge he was referred to an E.N.T. surgeon, who, obeying his instructions, recommended him to be recategorised to B.1. I presided over his medical board. His first anxious remark was : "You aren't going to lower me in category below A.2, are you, Sir ?" For he was the sergeant-major of a battery which he had helped to raise, and was most distressed at the thought that he might have to be posted away, as would be necessary if his category were lowered to B.1. Rarely did I have such pleasure in disobeying a regulation, and rarely did I see such gratitude from a soldier having a medical board.

Throughout my military career I saw large numbers of soldiers who, because each of their limbs, systems, and organs were structurally normal, had been placed in category A.1, and yet had never in fact succeeded in performing the dutes of an A.1 soldier, although belonging to active units. Given up as hopeless early in their military careers, they would spend their time when on duty in such unmilitary occupations as mess waiter, batman, or latrine orderly, while many had spent long periods away from military life, absent without leave, in prison or detention barracks, or in hospital.

The practice of ignoring the man but of concentrating all the attention on the parts of his body was also illustrated by the rule that soldiers could only be lowered in category or discharged at the recommendation of a specialist. If a man's foot was troublesome he had to be seen by an orthopædic surgeon ; if his nose, an E.N.T. specialist ; if his abdomen, a physician. Yet to assess a man's value as a soldier it would be absurd to pretend that a specialist was necessary, so this rule implied that the military value was of no importance. Many specialists, after the most exhaustive study of the region in which they specialised, would return a man to his unit with the statement that he had "nothing the matter," though the man was in fact utterly useless as a soldier.

sexually and asexually. As multiplication slows down, these bodies revert to the microcystic form, either directly or through the stage of a larger non-cysted nucleus. Such is a bare outline of Bisset's demonstration, which without his illustrations sounds bare and unconvincing. It is true that the evidence is based on the examination of stained material under a high magnification, and neither staining reactions nor nuclear division can by themselves justify the supposition that the processes observed by Bisset are identical with those seen in the larger cells of higher organisms. But the resemblance is there, and it deserves attention from a wider circle than the microbiologists, and an adjective more complimentary than "suggestive." Whether optical skill can carry the matter further we do not know, nor have we the knowledge to suggest investigations on the function of these bodies. Has all this anything to teach the medical bacteriologist? Apart from its value as a sermon on the virtues of mere curiosity, perhaps not; but there may come a time when new knowledge of bacterial heredity will have a startling impact on the theory and practice of epidemiology.

CRUELTY TO CHILDREN

PARLIAMENT has decided that a committee should be set up to inquire into the extent to which children in their own homes are neglected and cruelly treated. Such children are out of reach of the measures designed to protect children who are deprived of a normal home life, because they still have both home and parents; and one of the questions which the new committee will have to decide is whether officials should be given the right to enter the home to inquire into such cases, and what measures can appropriately be applied to protect the child and correct the parents. In this country we have always felt that the home should be forcibly invaded by officials only in the last resort—only, in fact, when a crime is being committed. It may fairly be argued that when a child is suffering cruelty, even at the hands of his own parents, then a crime is certainly being committed, and the right of entry can be justified. But in many cases the child is suffering not because his parents are cruel but because they are unequal to their responsibilities. Mrs. Ayrton Gould, who moved that the committee should be set up, quoted the case of a woman whose husband was serving a long term of imprisonment. Her six children were ill-fed, dirty, and verminous, and the whole family lived in a slum. She welcomed the help of the welfare officer, allowed five of the children to go into a local-authority home, and herself went into a voluntary home for the recuperation of mothers, taking the baby with her. After two months she was fit enough to go home and look after her children, and anxious to do it; and moreover she had been taught something about mothercraft. It is hard to see how official right of entry would have helped in such a case: the mother was ready to respond to the offer of help without coercion.

It seems that most of the cases will fall under this heading. The Women's Group on Public Welfare[1] found last year that the parents, and especially the mother, are more often poor, incompetent, ill, and fatigued than deliberately neglectful or cruel. Though 75% of a group of mothers in prison for child neglect were below the average in health when sentenced, not one of them had thought of pleading this as a cause of her failure—though many of them blamed bad housing and lack of money. In such cases the mothers are the victims of our own failure, and their children are secondary sufferers. This kind of neglect must be sharply distinguished from deliberate, or half-deliberate, cruelty. The neglected child and his parents may be closely attached to each other, and far greater harm will come to the child by removal from them than by physical neglect, bad as this is. On the other hand, where the child is being terrorised by a brutal or drunken parent or step-parent, the community should clearly be able to protect him. This very work has been done for 65 years by the National Society for the Prevention of Cruelty to Children, as Mr. Wilton McCann, the director, points out in a letter to the *Times* (Dec. 12); and it may well be best for such a voluntary society to carry on with a task which calls for so much personal judgment. He notes that of the 40,246 cases dealt with by the society last year, only 626 required a prosecution.

The committee's deliberations may indeed lead them to decide that this work must be done by a voluntary body rather than by statutory officials; but they must also consider what supplementary services the society needs to carry on with this work, and do it even better. First among these must surely stand mothercraft training homes—such as those founded by the Society of Friends, the Community Council for Lancashire, and the Salvation Army—in which the mother can live for a while with her children and learn to care for them properly. Housing difficulties must also be considered carefully, for a neglectful mother has even less chance of being rehoused than a capable one. The committee will also be able to establish another important point—whether cases of cruelty are increasing or getting fewer. In the House of Commons debate some held one view, some another.

MORPHINE ON THE MOUNTAIN

MORE than once the publicity of legal proceedings has been deliberately courted with the aim of putting an end to anomalies in the law. The latest instance has been provided by Mr. Wilson Hey, the Manchester surgeon, who invited prosecution under the Dangerous Drugs Acts for having supplied morphine to trained mountain rescue parties, in accordance with the policy of the Mountain Rescue Committee. Mr. Hey had twice applied for sanction of a direct supply, but without success, and on Oct. 26 he was fined by a magistrate.[1] At his appearance in court, Mr. Hey pointed out that mine rescue parties were already officially allowed to carry morphine. The mountaineer's claim to this concession seems hardly less strong; without the benison of morphine at hand, the severely injured climber usually faces a long and painful descent over a hill track as the alternative to waiting, possibly in wind and cold, until the nearest doctor reaches him.

Now the Home Office has notified the British Mountaineering Council of new arrangements which have been authorised. Morphine in gr. $^1/_4$ ampoules, up to a total of gr. $^3/_4$, may be packed in the standard mountain first-aid equipment which is stored at each of the first-aid posts formally established by the Mountain Rescue Committee. The morphine will be in the charge of the supervisor of the post, who will obtain replacements through a local general practitioner, accounting to him for ampoules used or rendered unserviceable. The council will supply to the Home Office a list of the first-aid posts, and will also furnish a statement each year of cases where morphine is used. The ampoules will be accompanied by printed instructions for administration and by a tag, for attachment to the injured man, on which the quantity administered together with the date and time will be recorded. At one post in an untenanted hut the emergency equipment, including the morphine, is to be kept in a locked cupboard which can be opened by a key stored in a glass-fronted box of the fire-alarm post type. The council is free to improvise forthwith arrangements along these lines.

WE regret to announce the death on Dec. 20, at the age of 45, of Dr. W. H. Newton, professor of physiology in the University of Edinburgh.

A preliminary way of assessing a recruit's military
, which has the virtue of extreme simplicity,
study of his performance in civil life—either taken
his history as given by himself or from reports from
employers. At present many soldiers have to per-
skilled trades similar to those of civil life. There
be no more convincing testimony of the suitability
man for the Royal Corps of Signals than that he was
'y efficient Post Office engineer, or for a commission
the R.A.M.C. than that he was a sound general
tioner.

regards the particularly military activities, such
marching in full kit, throwing hand-grenades, and
a rifle, useful information may also be obtainable
imes from a recruit's previous career. But in
respects the best time to classify recruits is towards
end of their period of preliminary training. A
d could be made of each man's ability in the more
rtant military activities, and from these records
authorities could decide which men should
sent to the infantry, which to the artillery, and
so on.

But even tests such as these do not give precise information about the functioning capacity of a soldier in *action*. And the only absolutely reliable way of assessing this—by putting him into action and observing the results—is obviously unsatisfactory, since so far as is possible men who are going to fail in battle should never be allowed into action at all. Moreover, in peace-time there can be no question of putting men to the practical test of fighting.

The qualities which cannot satisfactorily be tested on the training-ground, but which may cause a man to fail in battle, are the psychological qualities. An attempt should therefore be made to assess these qualities in all recruits, and they should be graded accordingly—though this is admittedly very difficult. The PULHEEMS system, by its admission of the quality S (emotional stability) certainly stresses the importance of character and temperament—in contrast to the previous system of categorisation. But under this system the assessment is made by a medical officer. Even if, with all the facts before him, a medical officer were able to make a better assessment than a non-medical officer (which is doubtful) his opportunities of studying recruits are so small that the opinion of the officer in charge of their training should be the determining factor.

In the Services a number of men are engaged in more or less highly skilled occupations, such as aeroplane pilots or tank drivers, which are rare or unknown in civil life. A recruit's civilian record, therefore, can give no direct information as to his ability in these occupations, and for obvious reasons all recruits cannot be tested in their actual performance. Means of selecting men for training in these occupations are, therefore, important. Intelligence and aptitude tests are doubtless very useful, and an assessment of character and temperament should be made as well. Consideration should also be given to certain separate bodily functions, notably the sight. Thus, whereas an exact standard of vision should not be laid down in respect of shooting (since the matter can easily be tested with a rifle and target) it is reasonable to insist that men with uniocular vision should not be trained as pilots. Similarly, it is perhaps sound practice not to train men with uniocular vision as truck-drivers—unless *they have already learnt to drive in civil life*. Nevertheless, hard and fast standards should still be avoided, since a man with some slight defect of vision but of strong personality will be more likely to make a successful pilot, say, than a man with perfect vision but of weak personality.

As previously noted, there is legitimate place for a medical opinion in assessing men's likely future capacities as soldiers. It would be proper, therefore, for each recruit to be seen by a medical officer who would supply a certificate of the following kind: "This man is not (or is), or has not been (or has been), affected by a disorder likely to recur or progress rapidly if he is a soldier." When this certificate is in the negative, no further medical action is needed. But when in the positive, the subject could rightly be brought before a *medical* board—or, at least, a board containing one or more medical men. The board could attempt to prophesy the likely rate of progression of the trouble, or the likelihood of recurrences, in a variety of circumstances of Army life, and decide whether any treatment practicable in the Army would influence future developments. Thus, it might be deduced that a man subject to eczema would probably suffer bad relapses in a tropical climate, and should therefore be kept in temperate zones. Cases which would form a problem here are those which it might be alleged would be damaged by the "strain" of Army life. For example, many doctors would say that the symptom-free subject of rheumatic heart-disease would be likely to develop cardiac failure if put into the infantry, though able to perform all the duties of an infantryman without distress. But good evidence to support this view is lacking. The statement that, in general, if a man is capable of certain duties there is no reason why he should not perform them seems sound. Even if it is probable that some individual would be harmed by the military life, this is hardly a sufficient reason for keeping him out of the Army in war-time. The additional hazard to him is surely a trivial matter by comparison with the enormous hazards freely taken by such men as the flying personnel of the R.A.F., submarine crews, and paratroopers. They are honoured for volunteering for their dangerous occupations; why, then, should a man with a raised blood-pressure be prevented from taking the slight risk involved by his joining, say, the field artillery?

Even when assessing such cases as these the problem whether or not to admit a recruit should not be considered wholly "medical." For one man with a specified liability to a certain disorder may be a most useful addition to the Army, either because of his other excellent qualities or his previous training, while another similarly affected man lacking these advantages may rightly be refused admission. Hard and fast rules excluding all men with certain disorders from the Army (such as those relating to peptic ulcer) should therefore be avoided. They can also be condemned from a purely medical standpoint, for most diseases vary infinitely in their course and severity from person to person. It is no doubt sound to keep a man out of the Army who is liable to frequent epileptic fits or has had numerous hæmatemeses over a short period. But another man of similar personality and qualifications who has had five epileptic fits in his life, the latest two years previously, or has suffered from a duodenal ulcer for one short period three years before, may be well worth recruiting.

After men have passed through the initial stages of their training and are attached to active units, there is no need as a rule for special tests to assess their functional abilities as soldiers. For they are continually undergoing the best test of all—that of carrying out the duties for which they are in the Army. A report from a commanding officer that a soldier has been tried and found wanting should, therefore, provide a supremely important ground for discharging him from the Army or transferring him to different duties. In action such a report should carry even greater weight than in training. There should, as I have already said, be two routes for evacuating men from the battle-line—the medical route for the acutely sick and wounded, and the non-medical route for the incompetents.

I do not suggest that the word of a commanding officer alone should settle the matter. Not every C.O.

As the war went on there was an increasing number of psychiatrists in the Army, and an increasing proportion of men were discharged or recategorised on psychiatric grounds. It could not be objected that psychiatrists did not take a soldier's military value into account, for they insisted on having a report on it from his C.O. But it must be wondered what was the need of the psychiatrist. For if the C.O. said the man was a useful member of the unit and the psychiatrist recommended his discharge from the Army, the latter was clearly wrong—as he was if the C.O. said the man was useless and the psychiatrist *recommended no change in category*. Indeed, in the matter of boarding the chief function of the psychiatrist *was to rubber-stamp the advice of C.O.s*, though he might have the added function of suggesting appropriate duties *for men found unsatisfactory in their present units*.

The high proportion of psychiatric discharges aroused much comment. "The statistics," says Adrian (1948), "are certainly rather alarming. It has been stated, and not contradicted, that from a third to a half of all medical invalids discharged during the war were discharged on psychiatric grounds. . . ." These figures seem to have proved: to psychiatrists that psychiatry is important; to the "tough old school" that these damned trick-cyclists are getting too influential; and to many ordinary people that the state of England's youth is very poor. Yet the figures simply reflected the introduction into the Army of the practice—universal in civil life—of judging a man not by his organs but by the way he does his work. It is taken for granted that the reason why a civilian is sacked is that he has a psychiatric defect.

Personally I always tried to frame recommendations about discharge from an assessment of the soldier's military value, to the extent that the regulation allowed, or could be ignored or circumvented. Leaving aside cases of severe maiming from battle wounds (with which I had little connexion) and perhaps pulmonary tuberculosis, I rarely saw a soldier whose *bodily condition alone* seemed to provide sufficient grounds for advising discharge from the Service. This does not mean that I rarely recommended discharge except by a psychiatric diagnosis; indeed, not being a psychiatric specialist I was not allowed to do this. A considerable proportion of the chronically useless soldiers had some organic lesion which could be made the nominal "disability" necessitating their removal from the Army; and otherwise there were plenty of labels, such as effort syndrome, chronic gastritis, chronic dyspepsia, second-grade constitution, or chronic fibrositis, which could be used for the same purpose.

THE PULHEEMS SYSTEM OF MEDICAL CLASSIFICATION

Since the war the PULHEEMS system has been introduced into the Army, and also into the Navy and Royal Air Force. Under this system the individual is examined with reference to seven subdivisions of bodily or mental function, the initial letters of which go to make up the word PULHEEMS, as follows:

P = Physical capacity.
U = Upper limbs.
L = Locomotion.
H = Hearing.
EE = Eyesight in each eye.
M = Mental capacity.
S = Stability (emotional).

There are 8 degrees under each quality, from the highest, 1, to the lowest, 8, though in the case of some qualities several of these degrees are not used in practice. Men of degree 8 in any quality are not normally accepted for service.

In the official instructions about the application of PULHEEMS, the importance of function, as opposed to structure, is stressed. Thus, it is said that: "T *decision (as to classification)* should be based primar on function, that is, the capacity to perform the wo involved in a *given type of duty*"; and, with referen to locomotion, "it is important that it be clearly und stood that L refers to the functional efficiency of the man locomotive system and not to any anatomical defect. . If the man can march with efficiency this will be express as L1 or L2, whether his feet are æsthetically pleasi or not."

These last sentiments are admirable. Unfortunatel the PULHEEMS instructions proceed to describe ho in many ways, the decision as to the degree und each quality should *not* depend on function. For examp in respect of P (physical capacity) it is said that, to graded *P1*, a man "should be above the average physiqu Height-weight ratio should be within the normal limi and chest measurements and expansion proportiona to build. General muscular development above averag . . ." In another place appears the *following* "Assessment of the man's physique is to be based upo careful observation of such general things as apparen muscular development, age, height, weight, and th correlation of these; potential ability to acquire physica stamina with training." Similar statements are give about the other degrees. It is also laid dow categorically that "evidence of mitral or aortic incom petence is a reason for placing in P8"; with referenc to varicose veins, that "lesser degrees of varicosity ma allow of P3 or P6. Minor degrees giving no troubl may admit of P3 or even P2"; and that "strabismu present in either eye will not be assessed *higher tha* P3."

Thus, in spite of the repeated stress as to the import ance of function, medical officers are compelled to considerable extent to ignore function and *act on struc* ture when assessing soldiers' PULHEEMS. Even if th eight qualities are all considered from a fully functiona standpoint, the system may still be criticised on the grounds that it takes no account of the function which really matters—that is, the *function of the whole man as a soldier*. An infantry unit needs men who are brave and resolute, are able to march long distances with full kit, and are accurate shots with rifle and other small arms. It is of small moment that such men are unable fully to extend their right elbows or flex their left knees, or are hard of hearing. A medical unit needs medical officers who are intelligent, possessed of a sound knowledge of medicine, hard-working, and able to inspire confidence in patients. It matters little that they should be missing one leg, one kidney, one eye, and one ear. Even if it is conceded that deafness in an infantryman or the absence of a leg in a medical officer are, other things being equal, a handicap to the efficient execution of their duties, these defects are trivial by comparison with their other qualities. The commander of a battalion, if given the choice between a brave, trustworthy, but deaf, man and a coward with perfect hearing would unhesitatingly choose the former. The PULHEEMS system, just like its predecessor, compels him to take the latter.

A SUGGESTED APPROACH TO CATEGORISATION AND DISPOSAL

Perhaps the fundamental error behind both the old and the new methods of classifying soldiers is that they are *medical* methods. For classifying men according to their functioning capacities as soldiers clearly does not require the services of a doctor. A doctor is needed in this connexion only to assess men's probable future functioning capacities. His opinion is not required except in the case of men suffering from, or thought likely to suffer from, some progressive or recurrent disorder.

man possibly be trusted in circumstances which are e to shatter the nerve of even the best type of soldier ? And is he not in the heat of action apt to be a hindrance to his fellows, and even perhaps to cause them to become alties ? Indeed, if anyone should be kept out of the battle-line, it is he. True, he should not be *invalided* out of the Army or lowered in *medical* category he often was in fact) but dismissed with dishonour. d. in so far as there is any truth in the view that gering can become infectious, the worst cases could sent to prison before their final removal from the y. with the object of discouraging others.

Perhaps another reason for the objectivity of the schemes of medical classification lay in the belief that to be objective is to be fair. During the war, when the try was in grave danger and nearly everyone was conscripted in some sort of way, it was an understandable feeling that it would be unfair to leave the individual to decide whether he should be a front-line soldier or not. When sitting on medical boards I commonly had arguments with fellow members who might say : " It would be damned unfair to let this dirty little so-and-so out of the Army when all the good chaps have to stay in and do their bit. I won't be a party to letting him escape." But this emotional attitude is quite indefensible. The object of classification should be to make the Army efficient, and the question of fairness is irrelevant (except in so far as a widespread *feeling* that there is much unfairness makes for inefficiency). Moreover, all the most dangerous jobs in the Services—submarine crews, flying personnel, parachutists, and commandos—were open only to volunteers ; and no method of selection could be more " unfair " than this.

Finally, a partial explanation for the Army policy of refusing to accept recruits with abnormalities is apparently to be found in pension considerations. A man who is admitted with a minor degree of hallux valgus which is causing no trouble may later develop (or maintain that he has developed) severe pain in the affected foot, preventing him from marching. He will then have a very strong claim for a pension on the ground that he has " a disability aggravated by military service." But even in peace-time this policy of refusing many excellent men because of the chance of one later behaving in this manner seems unjustifiable. In war-time, when vast sums of public money are being poured out in the prosecution of the war, and the number of people on the books of the Ministry of Pensions is inevitably enormous, the policy is absurd.

5. Implications for Civil Life

IF correct, the conclusions reached in this review of certain features of Army medicine have important medical and non-medical implications for civil life.

DIAGNOSTIC CRITERIA

The official Army attitude towards the diagnosis of malaria and amœbiasis exemplifies the widespread tendency in the medical world today to pay less attention to clinical findings than to the results of special investigations. Perhaps the fundamental reason for this tendency is that special investigations yield *objective* criteria. There is something attractive about a positive Wassermann reaction, a notched R wave in an electrocardiogram, a blood-sugar figure of 321 mg. per 100 ml., or the hæmolytic streptococci which are grown from the tonsils. For their reality cannot be questioned ; and they provide concrete evidence. Symptoms, on the contrary, are commonly so vague that it is very hard to be sure just what the patient's complaints are ; and even if the history is apparently definite, it is still somehow an intangible thing by comparison with a blood-urea of 180 mg. per 100 ml. or a polymorphonuclear leucocytosis of 21,000. It is true that many physical signs have not this " drawback," an enlarged spleen, a temperature of 103°F, or a diastolic murmur being just as objective and satisfactory as the flick of a muscle on galvanic stimulation or a titre of 1 in 1024 of *Bact. typhosum* antibodies in the blood-stream. But physical signs are probably wrongly emphasised just as often as the results of special investigations. (The attention paid to systolic murmurs some years ago is a good example.) The error in modern medicine which is being considered here, therefore, is the neglect of symptoms, rather than the neglect of clinical findings as a whole.

Platt (1947) says : " It has seemed to me for a long time that good doctors differ from bad ones in two major respects. The time they devote to history-taking and their ability to interpret a history correctly is the first. . . ." Later he adds : " Far more mistakes are made by putting too much significance upon doubtful physical signs and neglecting the clear indications of the history than by the opposite process." and he goes on to point out that in a high proportion of cases the correct diagnosis can be reached from the history alone.

In the study of acutely ill people the symptoms can be of great value in suggesting the diagnosis, or at least in suggesting the region where the lesion is to be found. But it is in the study of the chronic case that the history becomes very often of supreme importance. For deducing the cause of the symptoms—and this is the essence of diagnosis—is rarely the simple process of discovering some lesion. It involves, in addition, asking : first, whether a lesion which is known to be present is at all related to the symptoms (for incidental chronic lesions are common) ; and second, if this question is answered affirmatively, to what extent the symptoms can be ascribed directly to the lesion and to what extent to the state of mind (for the symptoms of many among the chronic sick with organic disease are predominantly or largely of psychological origin). Concentrating on the physical signs and investigations and neglecting the history can lead to the gravest errors. The bald diagnoses " mitral stenosis " or " anæmia " may be made when in fact the cardiac lesion or the state of the blood have little connexion with the symptoms, which are mainly emotional. The diagnosis " gallstones " may be made on the strength of shadows on the X-ray plate, when in fact these stones are causing no trouble and the real diagnosis should be " duodenal ulcer." The diagnosis " ankylostomiasis " may be made because of the finding of ankylostoma ova in the stools, when the symptoms are really due to amœbiasis. And the vast number of false " organic " diagnoses, such as visceroptosis, hyperchlorhydria, intestinal auto-intoxication, hypotension, strained heart, weak heart, and disordered action of the heart, which I have enumerated elsewhere under the title " The black chapter of medicine " (Todd 1949), can be made only by those who ignore the symptoms and concentrate all their attention on the physical signs and the results of special investigations.

The actual process of analysing persistent symptoms can also be most tedious and difficult. Very often a lengthy interrogation is needed before one even begins to appreciate what the patient is really complaining of. Among the chronic sick one of the commonest complaints is of feeling " generally unwell." Only after long questioning may it become evident that the real trouble of one patient with this complaint is mental depression, and of another generalised bodily weakness. As regards the chronic case, Platt seems justified in thinking that " good doctors differ from bad in the time they devote to history-taking and their ability to interpret a history."

ABUSE OF HOSPITALISATION IN CIVIL LIFE

In view of the practitioner's difficulty in getting his patients into hospital, the long waiting-lists in many is necessarily all-wise. Sometimes, indeed, an important reason for a soldier's incompetence is the attitude of superior officers who dislike and cannot handle him; if given better officers he may become an efficient soldier. Probably a satisfactory arrangement would be to bring together in appropriate units all the men who had been dismissed from their own units on the grounds of uselessness. There, with the aid of detailed reports under various headings from their commanding officers, observations on their behaviour by the personnel of the disposal unit, and various functional tests, it could be decided whether the men should be discharged altogether from the Service. retained in some different capacity, or retained in the same capacity. To such a unit could also be sent, when they have recovered from their wounds, soldiers who have been maimed.

When men develop in the Army some such recurrent or progressive disease as peptic ulcer or amœbiasis, or a disease likely to be influenced greatly by climate or surroundings, such as "sprue" or severe fungal infections of the skin, their disposal becomes, at least in part, a truly medical problem. They should be dealt with as already described in connexion with potential or actual recruits affected by diseases of this kind. Again, of course, hard and fast rules relating to certain diseases should be avoided, for considerations other than medical should nearly always influence disposal.

A matter which should be considered in all these situations is the individual's personal desires. Obviously, in so far as men can be given the kind of duties they prefer, they will be more efficient and of better morale than if forced into activities they dislike. Recruits who are keen to become soldiers will, other things being equal, be better than those who abhor the idea of the military life. This factor seems of particular importance in respect of those who have been maimed. A man who has lost a leg but is keen on staying in the Army will probably be worth retaining in some capacity, if he is of fair or good intelligence; a similarly afflicted man who is anxious to return to civil life should doubtless be sent there. Yet, in all the vast number of regulations and instructions on medical classification in the Army in both the old and the new systems, I never found a reference to the personal wishes of the individual. I do not suggest that these wishes should always count for a great deal, for in war-time men must be conscripted, and comparatively few soldiers would choose the infantry. But I do think that they should always be taken into consideration, and that sometimes they should carry much weight.

DISCUSSION

The above opinions, though at variance with official teaching, are in no way original. My theme—that, in the Army, men should be classified according to their ability to function as soldiers—is essentially the same as the universally accepted assumption about employment in civil life. The employer when selecting employees does not send them to a doctor to see whether they have hallux valgus, flat-feet, or a perforated eardrum, but chooses those who, from their previous record and their general behaviour, seem most likely to be efficient at the work he wishes them to do; if men have to be dismissed, those who go are the least efficient, not those who have a varicocele, albuminuria, or an ingrowing toenail. Why then, it must be asked, did the systems of classification described in this paper ever come to be evolved?

In civil life, it may be answered, people are not forced into, and held in, occupations against their will; but men are conscripted into the Army, or, even if they volunteer, are compelled to remain soldiers for a fixed number of years. It is easy to deduce from this that a system of classification from an assessment of the function of the man as a whole, which depends on willing coöperation, cannot be satisfactory, since he be apt deliberately to function badly, so as to escape fr the Army altogether or escape from a fighting u Accordingly (it is said) there must be some object system of classification. When I used to advance view that if a soldier is useless to the Army, he sho obviously be discharged, I was—at least when statio in base areas thousands of miles from the enemy—so times answered by the retort: "Good heavens, if eve one knew that any lead-swinger could get his tic just by making himself inefficient, within a mo hardly any Army would be left."

To this it can be replied that even during the ea phases of the war some aspects of categorisation notably hearing and vision—depended on the coöpe tion of the subject; that later on intelligence tests, whi have the same "drawback," were universally use and that rejection and discharge on psychiatric groun became increasingly common. The PULHEEMS syste which stresses so strongly the function of various aspec of the individual, largely depends on the subjecti factor. Yet I have hardly ever heard of men deliberate pretending that they were less intelligent, or of poor vision or hearing, than they were in fact.

In the R.A.F. any flying man who reached the co clusion that he had had enough of the frightful hazar of his life could say to his C.O. that he was unable carry on any longer, and was then permanently tran ferred to ground duties, because of his "lack of mor fibre." Yet according to R.A.F. officers there was nev any suggestion that a flying man who was still capab of his duties would deliberately escape in this manne It is true that these men were all volunteers of goo calibre, and if grounded because of "lack of moral fibre were reduced to the rank of aircraftman. But if in th Army there had been a procedure by which men in th front-line infantry could have been made, say, clerks i the Pay Corps or nursing orderlies in the R.A.M.C. because of "lack of moral fibre," would men o sufficient character to be any use in action hav incurred the contempt of others by employing thi means?

So far from discouraging malingering, I believe tha the "objectivity" of the medical classification schem during the war had precisely the reverse effect. If, by repeatedly reporting sick, with, say, pain in the back, a man succeeded in getting himself invalided out of the Army, the solemn procedure of a medical board—consisting of three doctors, one at least a lieut.-colonel—was to inform him that he was *unfit for any form of military service* on account of chronic lumbar fibrositis. What could be more calculated to salve his conscience? Even though an uneasy voice at the back of his mind occasionally told him that his backache had not been so bad as he had said it was, a much louder voice could reply: "Three doctors have discovered that I'm unfit and they ought to know; I didn't ask for my ticket: it's not my fault that I'm back in civvy street." And his friends and relatives in civilian life would welcome him home as a hero, his health ruined by the hardships of military life. Whereas, if the process of getting out had been to be told, by a high officer: "You are a useless incompetent without the guts to deserve the honour of wearing the King's uniform," it seems most unlikely that many men would have been so base as deliberately to escape from the Army in this way.

The question of malingering can be looked at from another angle. Though the old sweat who reports to the M.I. room with a bad attack of "backache" on the day of a route-march may be quite a useful soldier in action, the habitual chronic malingerer must have a defect of character so gross as to be quite useless in battle. How could such

At least one disorder—epilepsy—may nevertheless the refusal to give even an adult certain occupa- ns, though the only person who can thereby suffer himself: if he works close to machinery or has to mb ladders he will be liable to kill or maim himself: d it seems reasonable to prevent him from doing this. iere may also be a strong case for stopping juveniles m damaging themselves. But to prevent a grown an from taking the job of his choice is as a rule a grave terference with the liberty of the subject. When note (*a*) that the prevention is done by a single edical examiner, against whose decision there is no peal; (*b*) that there is no clear knowledge of how uch different kinds of work may damage people with rtain diseases; and (*c*) that different doctors some- nes come to entirely different conclusions about the me case, the degree of this interference seems intoler- le. One often hears it said that the traditional erties of England are gradually being filched away. ut the kinds of things to which this statement refers, ch as the compulsory use of identity-cards, the striction in taking money out of the country, and the merous regulations of various Government depart- ents, seem trivial in comparison with the practice of rbidding someone to take a job because of the opinion a single medical man. It is strange that apparently voices have been raised in protest.

3. To an employer the answer to the question “will is man be likely to give continuous effective service r an indefinite period?” is valuable, since reliable nployees are more useful than unreliable employees. nd at a medical examination a doctor may sometimes able to conclude with confidence that a person has undue liability to illness, or a shortened expectation life. But if to refuse a man a job because he may rm himself is an infringement of liberty, to refuse him ecause he may, through no fault of his own, prove reliable seems a shocking injustice. The victims of vere asthma, tuberculosis, peptic ulcer, rheumatoid thritis, and other recurrent or progressive diseases ve misfortunes enough. If in addition no-one will nploy them, their fate is melancholy. In recent years ey have been the subject of sympathetic legislation, r a law has been made compelling employers to accept proportion of disabled men. As regards the National ealth Service, whereas originally the newly appointed d to be certified as free of physical defect or disease hich appeared likely to prevent continuous effective rvice *in the future*, the doctor is now only asked give his opinion on the candidate’s present ndition.

4. When the candidate for a job is a potential danger his fellow workers and others, there may be the rongest reasons against appointing him, however rd his fate may in consequence seem. But there seem be only two common conditions—pulmonary tuber- losis and epilepsy—whose victims are liable to objection this account. And only in a few occupations, such driving a vehicle, is the epileptic dangerous to other eople. Undoubtedly there are a number of conditions, cluding such skin diseases as widespread psoriasis, hich are so frightening or unpleasant that their subjects re apt to be treated almost as lepers. Yet to refuse man a job because he has one of these conditions ould be as bad an injustice as to refuse him because has an undue liability to fall sick. In so far as a octor is concerned in this sort of situation, his efforts hould be directed to removing the prejudices of those ho object to the near presence of unfortunate people ith skin diseases and other unsightly or unpleasant isorders.

We may therefore conclude that there is no real place r a medical examination as a part of the selection of adults for jobs. To assess a man’s capabilities is not a medical problem; to refuse him work because he may damage himself is nearly always an unwarranted interference with his personal liberty; to refuse him because he may be unreliable through bodily disease is unjust; and, with the exception of two conditions, it is highly unlikely that he will be a danger to others, whatever diseases he happens to have. And perhaps the most important disorder which should legitimately influence the work which a man is *allowed* to do—namely, epilepsy—cannot be discovered by objective examination: in its detection a certificate from *a candidate for a job* that he is free of it is all that is needed. For juveniles a medical examination before acceptance for work is conceivably justifiable, though even in their case there is very rarely convincing evidence that doing a job of which they are capable will in any way harm them.

6. Summary and Conclusions

1. In the diagnosis of malaria and amœbiasis too great an emphasis was put upon the microscopical aspects of the problem, by comparison with the clinical, during the Burma campaign.

This practice provides an example of the common modern error of exaggerating the importance of special investigations by comparison with clinical findings, and particularly with symptoms.

2. Soldiers were admitted to hospital too often with malaria: they were retained there too long with amœbiasis and other acute diseases: and they were wrongly admitted for investigation and disposal.

Civilians are also sometimes retained in hospital too long, and are wrongly admitted for investigation and the medical treatment of certain chronic conditions.

3. The method of medically classifying soldiers during the late war, and to a less extent the present PULHEEMS system, are wrong because they depend on structure or on the function of single parts or organs of the body. Soldiers should be classified according to their ability to function as such.

The medical classification of civilians for jobs is unnecessary, often unjust, and sometimes interferes with the liberties of the subject.

I wish to thank my father for his valuable help in revising this paper, and Dr. Frank H. Scadding for his advice and criticism.

“. . . Reverting to the tropic hormones of the anterior pituitary, it should be noted that these are by no means the only examples. There seems to be a fairly general and adaptable mechanism whereby the appearance of a protein stimulates the formation or release of various steroid hormones at different sites in the body. There must be some common factor in these processes, and it may not be so far from our reach as we imagine. There is a widespread belief that steroid hormones are intimately connected in some way with malignancy, and for this reason alone research in this field must be vigorously pursued.”—Sir ROBERT ROBINSON, P.R.S., *Nature, Lond.* Dec. 17, p. 1023.

hospitals, and the shortage of nurses causing many beds to be kept empty, the title of this section may appear strange. And, doubtless, there is nothing in civil life corresponding to the abuse of hospitalisation in the Army which I have been describing. For many of the disorders which hospitalised the soldier—e.g., gonorrhœa, malaria, tonsillitis, and bacillary dysentery—the average civilian would never dream of going into hospital. Nor are patients admitted to civilian hospitals for purposes of disposal.

In some respects, nevertheless, the abuse of hospitalisation in the Army has its counterparts in civil life. Perhaps the best example of this is the practice of admitting patients with chronic complaints for investigation, which is often futile or harmful for reasons similar to those given in the third part of this paper. Many people with chronic or recurrent treatable complaints—e.g., diabetes, pernicious anæmia, and peptic ulcer—are also, in my opinion, wrongly admitted for treatment. Admittedly, it is commonly held that those with peptic ulcer should go to hospital in their "early, curable stages" so that they can be treated vigorously and the development of the serious phases of the disease prevented. But there is apparently no sound evidence behind this argument, while a study of the natural history of the disease suggests strongly that it is false: it is very hard to understand how even the most intensive treatment now should prevent the recurrence of an ulcer in a year or two's time. Again, among the patients who really need hospital care many seem to be retained too long. In surgical wards they may be unnecessarily admitted several days before their operations—perhaps for investigations which could have been performed when they were outpatients—and unnecessarily retained for some weeks afterwards. In medical wards, convalescents from acute illnesses are sometimes not discharged, though they seem quite well and their home conditions are excellent, because of a vague fear that something may go wrong. In teaching hospitals the additional reason that a patient is a "good teaching case"—i.e., has numerous exciting physical signs—may delay his discharge.

It seems, therefore, doubtful whether the genuine shortage of ordinary "short-stay" beds in this country now is as great as it appears. If the only patients who were admitted to such beds were those who might reasonably be expected to *benefit from being there,* and if they were discharged as soon as they had ceased so to benefit, there might be room in hospital for many acutely ill people who are now looked after to their disadvantage in their own homes, and the swollen surgical waiting-lists might soon disappear. As regards the beds used as permanent homes for the chronic sick, who cannot otherwise be looked after, the position is of course very different. There is, and doubtless will continue to be, a shortage of such beds, because few nurses are willing to look after their typical occupants—old people with senile dementia, incontinent of both fæces and urine, and commonly with the sequelæ of a stroke or strokes.

MEDICAL CLASSIFICATION IN CIVIL LIFE

I said in the fourth part of this paper that, in contrast to Army practice, men in civil life are employed or dismissed because of their ability or inability to do their work, not on the strength of a medical examination. But this statement is not now altogether true, for in recent years an increasing proportion of men have had to go through some sort of medical examination to determine their "fitness" for their desired occupation. In one particular field—the employment of juveniles in factories—such examination started more than a hundred years ago. Under the Factory Act of 1844 certifying surgeons were appointed who were empowered to examine children and issue the following form certificate: "I certify that I have today examined person . . . and am satisfied that such person is of age . . . and is not incapacitated by disease or bod infirmity from working daily in these works for the ti allowed by law for a young person." In 1937 certifying factory surgeon changed his name to that examining surgeon. As such he had the power reject a youngster as unfit for work. Quite apart fr this legal insistence on a medical examination for juveni many large firms and public bodies have their o private rules on the matter. Hospitals, for example, ha for years required that all their potential nurses shou be passed as medically "fit" before being accept Today each person appointed to the National Heal Service must be certified by the examining doctor "free from any physical defect or disease which n impairs his capacity satisfactorily to undertake t duties of the post for which he is a candidate."

When a man is medically examined before bei accepted for some kind of work, an answer may required to each of the four following questions:

1. Is he capable of doing the work?
2. Is it advisable, for his health's sake, that he should do t work?
3. Will he be likely to give continuous effective servi in the work for an indefinite period in the future?
4. Will he be a danger to others?

These questions will now be considered in turn.

1. I concluded in my fourth section that the asses ment of a man's present capabilities as a soldier is not medical matter at all. This is even more true of civ life. The way to decide whether a man can efficiently he coal, lay bricks, write leading articles, or direct a compan is either to study his previous record in these direction or to give him an appropriate examination. Yet th form of medical certificate laid down for candidate to posts in the National Health Service (given above requires only a statement about his capacity. If candidate for a clerkship has been selected by an appoint ments board because his testimonials provide clea evidence that he is in fact efficient in clerical work the doctor cannot say that he is incapable of it.

2. I also concluded that if a soldier is continuously capable of certain duties there is rarely any good reason why he should not perform them. A similar conclusion can be reached about work in civil life. Admittedly this conclusion would not be universally accepted in medical circles: many doctors adv [illegible] who have had a coronary thrombosis, or have [illegible] or a liability to peptic ulcer, not to perform heavy manual work, though they can do so without distress. But, whether they are right or wrong in this, it is clear that the function of the doctor who is examining candidates for a particular job is not to *advise* them as to the kind of occupation they should undertake, but *to accept* or *reject* them. Even if it is true that a person would be ill-advised to take some particular work, it may not be justifiable to forbid him to do it, when he is quite aware of the risk he runs. This is one example of the general question as to how far society is justified in compelling individuals to refrain from actions which harm no-one but themselves.

Now, it appears to be the common opinion in this country—and it is an opinion with which I concur—that men should in general be free to do what they like, provided that they do no direct damage to anyone else. And as a rule the Law supports public opinion in this matter, making no attempt to prevent people from, say, drinking excessive amounts of alcohol, climbing precipices, engaging in motor races, or going on expeditions to the South Pole.

hising to some extent with this objection, the points out that "the National Insurance Certification) Regulations, 1948 (S.I. 1948, 1175), provide, in paragraph 3 of the Schedule, that in the practitioner's opinion, a disclosure to the t of the precise cause of incapacity would be udicial to his well-being, the certificate may contain s precise statement."

PARA-AMINOSALICYLIC ACID AND STREPTOMYCIN IN PULMONARY TUBERCULOSIS

CLINICAL trial of *p*-aminosalicylic acid (P.A.S.) and ptomycin in pulmonary tuberculosis was undertaken 1948 by the Medical Research Council, with the eration of the British Tuberculosis Association. The l is not yet completed but some of the results already ined are so important that the joint committee onsible for guiding the trial has decided to issue the wing preliminary statement.

major disadvantage of streptomycin is that the od of effective therapy is limited in many patients the emergence of streptomycin-resistant strains of rcle bacilli after five or more weeks of treatment. y workers have suggested that the addition of her tuberculostatic agent might suppress the resistant strains, which in the initial phases are present in small numbers: published reports on a few cases ted with P.A.S. and streptomycin have been encourag- The present investigation was planned to examine, he method of controlled trial, the possibility that . has this property, and at the same time to assess clinical effect of this drug alone and in combination streptomycin.

PLAN OF TRIAL

hree treatment groups of over 50 cases each were rved: (*a*) P.A.S. alone (20 g. of the sodium salt); (*b*) streptomycin alone (1 g. daily); and (*c*) both s together (20 g. of the sodium salt of P.A.S. and of streptomycin daily). The methods were similar hose employed in the first M.R.C. clinical trial of ptomycin in pulmonary tuberculosis,[1] and the type ase was again defined as follows: acute rapidly ressive bilateral pulmonary tuberculosis, of recent elopment, unsuitable for collapse therapy, in young ts aged 15–30. After acceptance for the trial by a l, patients were allocated to one or other of the e treatment groups by a method of random selection. prescribed treatment was given for three months ach group. Clinicians and pathologists at eleven ital centres have coöperated in this investigation, ing uniform records, using standard clinical and eriological procedures, and reporting results at regular vals to the council's Tuberculosis Research Unit, re the grouped results have been analysed.

PRELIMINARY RESULTS

r this well-defined type of case of pulmonary rculosis, the trial has demonstrated unequivocally the combination of P.A.S. with streptomycin conably reduces the risk of development of streptoin-resistant strains of tubercle bacilli during the onths following the start of treatment. This conon is applicable so far only to the acute form of se treated, and it remains to be seen whether the e results are obtainable in other forms of tubercuamenable to streptomycin therapy. Furthermore, conclusion is applicable only to the large dose of used; this dosage causes discomfort in some patients and it has been agreed to find out, by further trials, whether smaller doses would achieve a same result. It must be stressed also that streptomycin is effective only in certain forms of tuberculosis, and the finding reported here must not be interpreted as indicating that a combination with another drug will be effective in those forms for which little result would be expected from streptomycin alone.

THE NEW ZEALAND ELECTION

FROM OUR NEW ZEALAND CORRESPONDENT

AT this general election on Nov. 30, the National Party was returned with the substantial majority of 46 seats to Labour's 34, the latter figure including all the 4 Maori seats. The Labour government's fourteen years of office thus came to an end, and Mr. S. G. Holland has assumed office as prime minister. The new minister of social security and health is Mr. J. T. Watts, of Christchurch, a barrister and solicitor about 40 years of age with a distinguished academic record, who entered parliament six years ago.

The National Party's election policy emphasised prevention and research, and promised a complete reorganisation of the hospital system on a basis of regional control and decentralisation. It supported recent Acts for the more economical management of medical and pharmaceutical benefits, and promised help for the elderly, for the Post Graduate Women's Teaching Hospital in Auckland, and for a number of other projects. With recent and forthcoming appointments inside the health department—notably that of the new director-general, Dr. J. Cairney—the field is open for much-needed progressive development.

The Labour Party's fourteen years saw the introduction, in spite of war-time difficulties, of an almost complete series of medical and allied benefits under social security, specialist services being the only major gap. The fee-for-service principle in maternity and medical benefits was dominant. Little change in hospital organisation and planning was undertaken, though during this era the government came to be much more responsible for finance than formerly.

Public Health

Typhoid on a Liner

WHEN the liner s.s *Moollan* arrived in the Port of London on Dec. 16, three sick members of the crew were removed to hospital for observation. On subsequent days further members of the crew were admitted to hospital, and a diagnosis of typhoid fever has now been confirmed in some of them. On Dec. 22 a total of eleven confirmed cases were under treatment, and five further members of the crew were under observation in hospital. The organism is Vi-phage type A. Retrospective inquiries suggest that the dates of onset of illness were during the last ten days of the voyage. One passenger has been admitted to hospital as a suspected case of enteric fever. The names and addresses of passengers and members of the crew who left the vessel have been notified to medical officers of health of the destinations to which they were proceeding.

Poliomyelitis

In the week ended Dec. 10 notifications in England and Wales numbered: poliomyelitis 124 (141), polioencephalitis 10 (15). Figures for the previous week are shown in parentheses. The total of 134 notifications of poliomyelitis and polioencephalitis together may be compared with figures of 76 in the corresponding week of 1947 and 36 in 1948. In 1926 the corresponding

MEDICAL CERTIFICATES

INTER-DEPARTMENTAL COMMITTEE'S REPORT

Two years ago the Minister of Health and the Secretary of State for Scotland set up a joint committee, under the chairmanship of Mr. Archibald Safford, K.C., " to consider the medical certificates required under present enactments or regulations or for other administrative purposes," and to advise how far it would be possible to reduce the number of certificates to be signed by practitioners and to improve and simplify the forms of certificates and the rules governing their issue.

In its report,[1] issued this week, the committee asserts that the increasing demand for certificates is to the disadvantage of both doctors and patients; and the best way to reduce the number of certificates would be for the Ministry of National Insurance to provide, at the request of insured people, extracts of certificates of incapacity which could be used for more general purposes than at present—for presentation to employers, for example.

The committee points out that some certificates and forms are of great complexity, and it recommends that each department should be asked to review, with the aid of its medical advisers, the possibilities of simplification.

> " One general point can clearly be made. It is of great assistance to a person called upon to complete a document if he is familiar with its lay-out. If the same questions are asked but they are printed in a different order or in different type or on different sized paper or on different pages of the form in question, the identity in content of the two documents will escape the observation of the person dealing with them until he has studied them with care. A doctor familiar with one form, called upon to sign the other, may approach it as an unfamiliar matter which requires preliminary and wasted study. Even if a few additional questions need to be asked in one of the documents they may be so placed as to form a separate and easily recognisable group."

Further general suggestions are that: (1) it is convenient to leave the place for the date immediately under the doctor's signature; (2) it is unnecessary to make the doctor write in the name and address of the patient if this appears elsewhere on the form; and (3) a general inquiry about disease should call for the enumeration of symptoms or signs rather than ask whether the patient is free from disease. " In the future in preparing new forms of certificates it would seem to be desirable that advice and assistance should be obtained from some joint committee representative of medical and other interests with legal guidance available to them."

The committee abstains from drastic recommendations since it believes that without knowledge of the day-to-day working of a control it is usually impossible to say whether a particular question can be eliminated. Instead, it lists the many certificates and other forms that the doctor may be called on to sign, so that those requiring them may be able to consult and avoid duplication, and where possible adopt the same or similar forms.

The report suggests that

> " the doctor's function in relation to the signing of certificates is to provide evidence of medical facts or inferences and does not extend to a general assurance that the application or other matter in respect of which such a certificate is used is founded on a true presentation of the other facts of the case. Instances of the inclusion of such non-medical matters in the forms at present in use may often be found."

Furthermore, the doctor should not be called on to state as a medical fact something of which he has no personal knowledge.

The committee recommends that section 33 (2) (*d*) of the National Health Service Act, 1946, and section 34 (2) (*d*) of the National Health Service (Scotland) Act, 1947, should be amended to provide for the free issue only of " such certificates as may be prescribed, being certificates reasonably required under or for the purposes of any enactment."

SPECIFIC RECOMMENDATIONS AND CONCLUSIONS

Admiralty.—The committee suggests a variation of layout in the forms of attestation.

Ministry of Agriculture and Fisheries.—Local agricultural wages committees should be encouraged to assess percentage disability by personal observation.

Commonwealth Relations Office, Division B.—A normal certificate of cause of death is all that need be produced with form 178 (Military Dept.).

Ministry of Education.—This department should reduce the demand for certificates where a child is absent from school to cases where the allegation that the child is ill is believed to be false, or where the situation is one which a layman cannot judge.

Ministry of Food.—(*a*) The length of validity of a certificate of the need for special rations for active workers should be at the doctor's discretion, and not restricted to one week; (*b*) form R.G.50A puts an unwarrantable burden on doctors (this form, which has to be completed to enable patients with active polyarthritis to obtain extra milk, includes the question: What is the value of the sedimentation-rate?).

Ministry of Health.—(*a*) The demand for a certificate for an ambulance is unjustified, except in special circumstances; (*b*) the provision of a certificate to obtain a district nurse or home help is not convenient or necessary; (*c*) one certificate should suffice for all purposes to obtain a specially made surgical corset.

Home Office.—(*a*) Form Port 12 should be revised so that the duplicates may be made by carbons; (*b*) the forms used by fire authorities should be coördinated.

Ministry of Labour.—(*a*) Modification of form DP32 is suggested; (*b*) wages boards and wages councils should be encouraged to assess percentage disability by personal observation; (*c*) the certificate of probable absence of a trainee should be dropped.

Ministry of Pensions.—Instead of MPC21, a form similar to form BW2 of the Ministry of National Insurance might be used.

Ministry of National Insurance.—(*a*) The books of medical certificates should be provided with counterfoils, and they should be distinguished by different colours; (*b*) there should be longer intervals between certificates in the case of long-term and permanent incapacity; (*c*) existing arrangements for the provision of extracts of certificates (which are already to be supplied for the purposes of a friendly society or trade union from which the insured person is claiming benefit on the ground of incapacity) should be extended to more general purposes.

Ministry of Transport.—Slight alteration of form PSV15A is proposed.

Scottish Education Department.—(*a*) The form of examination for candidates to train as youth leaders is unnecessarily elaborate; (*b*) Form 189 is unnecessary with the use of form 9T.

Scottish Home Department.—The committee does not consider a certificate " on soul and conscience " to be a certificate in the sense in which it is used in the National Health Service Acts.

OTHER OBSERVATIONS

In its evidence the British Medical Association proposed two standard forms of certificate which, it was contended, would be suitable for most purposes. One form was for National Insurance use, while the other was drafted to cover all cases where the patient needs medical evidence in order to attain some necessary object. The association proposed that the condition of the patient should not be stated specifically but should be classified according to categories known to the doctor but not to the lay person who would normally handle the certificate; concern was expressed at the increasing divulgence of diagnosis as the result of universal certification. While dier RAYNER: Will the Minister do something about Does he realise that in many of these small cottage 's, offering very few amenities, they have to charge than the London Clinic; that a great many old people to have extra privacy and are quite able to pay reason- or it, but cannot pay fantastic prices; and does he that doctors, nurses, and patients are absolutely fed the whole business as regards private rooms? AN: The hon. Member has entirely exaggerated the The fact is that so long as there is need for hospital dation it is not desirable to relax the situation so ple can buy their way into hospitals before those who hem more. Brigadier RAYNER: In view of the bank- ature of the hospital service, can the Minister afford the revenue from these private rooms? Mr. BEVAN: ospital service is no more bankrupt than the resources nation.

---

[1] Ministry of Health and Department of Health for Scotland. Report of the Inter-Departmental Committee on Medical Certificates. H.M. Stationery Office. Pp. 102. 2s.

WILSON HARRIS: Does not the Act already provide ny patient needing a private room for medical reasons it over the head of anybody else, and is it not rather ate position as a result of this Act that these very prices should be charged? Mr. BEVAN: The hon. confuses the situation. There are two types of dation in hospitals for which a charge is made. There amenity bed for which one only has to pay for the and there is the other where one has to pay for the n and the medical service if one insists upon having s of a particular kind. In most hospitals it is now to have both. In this hospital to which reference is if the beds are empty, they are made available to who need them urgently. Brigadier RAYNER: Who to buy them at 19 guineas a time in a small cottage al? Mr. BEVAN: The answer is that if they cannot em at that price they can have them free if they need urgently.

A General-practitioner Hospital

G. W. ODEY asked the Minister why it had been decided e Beverley Cottage Hospital should cease to be a general- ner hospital as from Jan. 1 next; and why this had been taken without any consultation with the management committee, the members of the public ley and district, or the local medical profession, in ention of the advice given to regional boards in his 's circular R.H.B. 49 (132).—Mr. BEVAN replied: d that the board took their decision before my was issued, but that they have now asked the manage- mmittee to consider the practitioners' representations. bject is to make full use of beds, staff, and facilities, have not been fully used up to now.

Hearing-aids

GERALD WILLIAMS asked the Minister if he had dis- d the percentage of persons who could not be fitted the "Medresco" hearing-aid; and if he proposed to distributing centres of aids to the hard-of-hearing y other hearing-aids until the new medresco was —Mr. BEVAN replied: I am advised that the per- likely to benefit from a different electrical aid is less . The answer to the second part of the question is r. WILLIAMS: Will the Minister bear in mind that hen the medresco hearing-aid is available in quantity not suit everybody, and will he therefore give the of other hearing-aids a chance of letting the public heirs?—Mr. BEVAN: At the moment we are investigat- possibility of having an aid which will be suitable for than 5% of the hard-of-hearing, and when that aid able it will be distributed freely like the medresco I hope to be able to make an announcement before

W. S. SHEPHERD: Are those unfortunate 5% to wait any relief because of the obstinacy of the Minister?— EVAN: No, but I am not prepared to mulct the ers to provide commercial aids.

Treatment of Sex Offenders

JOHN CORLETT asked the Home Secretary to what it was the practice in prisons for prison medical officers ing men sentenced to imprisonment for sex offences drugs which destroyed the sexual urge.—Mr. CHUTER plied: No such drugs are being administered by prison al officers.

In England Now

A Running Commentary by Peripatetic Correspondents

CHRISTMAS AT THE E.B.S.

Doctor Wenceslas rang up,
On the Feast of Stephen,
Just before he sat to sup,
Latish in the even:
Wildly shrilled the bell that night,
Witness to his fury,
Telephoning in his plight
Number Ten, Old Jewry.

"Listen, girl, I want a bed,
And I want it quickly,
Mrs. Binks is nearly dead—
Or at least is sickly."
"Sir, I pray you, what is wrong?
Has she tertian fever?
Soon, I hope, we'll send along
Someone to retrieve her."

"Hackney, can you take her in?
Or can you, St. George's?"
But the staff were sufferin'
From their Christmas orgies:
So the maidens, one and all,
Dialled London madly,
Telling every hospital,
Mrs. Binks was badly.

"Sir, there's nobody about,
I have tried each number,
Porters to a man are out,
Housemen wrapped in slumber."
"Girl, I will not take excuse,
Mrs. Binks is worser:
Ring until the wires fuse,
Or yourself shall nurse her."

Far their clarion call they sent,
Sleepers to awaken:
By the last establishment
Mrs. Binks was taken.
Therefore, maidens, all accurst
By G.P.s be reckoned,
If you ring the ninety-first
But not the ninety-second.

* * *

Each year we try to do something distinctive at our Christmas party, to mark it off from other parties at other times. This year we demanded that our guests should wear evening dress: the men grumbled but the women loved it. In our household there was distressing talk of my missus getting a new evening gown until I persuaded her that her 12-year-old one was the best of all. She sewed some lace round the edges, and on the evening I actually believed what I'd said. We limited the number to twenty-five, and included a fair sprinkling of foreigners—Swedish, Danish, French, Russian, and ex-German—chiefly because we like them but also because they know that a party is the place for chatter and laughter, however indiscriminate. The drink question I solved empirically half an hour before the guests began to arrive at 8. I found that one part of rum, two parts each of gin, dry vermouth, and orangeade, and four parts of dry cider made an innocent-tasting mixture. (Those who find it too dry can sweeten it with sugar or—here's a tip—with just a touch of glycerin.) Working out this problem cheered me up enough to greet the first guest with suitable warmth.

For an hour we left them sipping in peace—with relief I noted the hum of talk rise from basso pianissimo to alto con esprito—and then we started them on the first game. In my view games are all right if they are few and short and make no demands on the mind. This year we chose the game in which one pins the name of a different hero or heroine, dead or alive, on the back of each guest and makes them guess their identities: they can ask each other guest not more than three questions, and the answers must be Yes or No. Then, after a pause, we went on to the drawing game. The party is divided into teams of six or so;

figure was 43 and in 1938 it was 30. Multiple cases were reported from the following counties:

London 15 (16), Bedford 2 (0), Buckingham 3 (2), Cambridge 3 (1), Chester 4 (2), Cumberland 3 (0), Devon 2 (0), Dorset 4 (1), Essex 10 (7), Gloucester 2 (7), Hertford 3 (2), Kent 8 (10), Lancaster 9 (14), Middlesex 6 (15), Norfolk 4 (4), Northampton 2 (1), Nottingham 3 (6), Southampton 2 (5), Stafford 3 (5), Surrey 6 (6), Sussex, East 5 (4), Warwick 5 (6), Yorks, East Riding 2 (0), Yorks, West Riding, 13 (19), Glamorgan 4 (6).

New Regulations.—The Public Health (Acute Poliomyelitis, Acute Encephalitis, and Meningococcal Infection) Regulations, 1949 (S.I. 1949, no. 2259), will replace, with slight modification, existing regulations on the notification of these infections. Under the new regulations, which come into force on Jan. 1, "acute polioencephalitis" will be included under "acute poliomyelitis," which will be notifiable as "paralytic" or "non-paralytic." Acute encephalitis will be notifiable as either "infective" or "post-infectious following. . . ."

Parliament

Nutrition Policy

IN opening a debate on nutrition on Dec. 15, Mrs. C. S. GANLEY reminded the House of Commons that in 1936 4½ million people spent only 4s. a week on food; 9 million spent only 6s.; and a further 9 million only 8s. Lord Boyd-Orr had declared the first of these diets to be inadequate; the second to lack proteins and fats; and the third to provide insufficient vitamins and minerals. Today, Mrs. Ganley continued, 336·7 lb. of liquid milk was consumed per head per year compared with 216·9 lb. before the war, and though the consumption of butter was now 12·5 lb. compared with 24·8 lb. before the war, there was little difference between the pre-war and present-day total consumption of fats. With their priority allowances for their children and themselves British mothers were better cared for, and their children were better born, than ever before in our history. Mrs. Ganley quoted Professor Bonnet, a leading French specialist, who when inspecting English school-children in 1948, said that in ten years England would have a generation of young men and women superior physically and mentally to that of any other European country.

Mr. SOMERVILLE HASTINGS pointed out that there was a world shortage of food and every country was affected by it. The less highly developed countries were now claiming their right to share in the world's supplies. By rationing we had provided to some extent fair shares for all, and by food subsidies we had ensured that the important foods were within the reach of even the poorest section of the community. About a fifth of the people were now getting less food than before the war, and about two-fifths were about the same, but the remaining two-fifths were now receiving much more food. As a result the health of our people had, on the whole, been extraordinarily well maintained. He was not forgetful that at present there was a very high incidence of tuberculosis, but this was probably due to the fact that the disease was much more often recognised than it was before the war. There was no clear evidence that the death-rate from tuberculosis was increasing, and the death-rate was the really *important* guide as to the nation's nutrition. On the whole the recent white-paper on Food Consumption Levels in the United Kingdom [1] was most reassuring. But he was a little unhappy about vitamins, and about fats which were some 16% below pre-war. Also he wished we ate more fresh fruit. Though we had increased our vegetable supply by 10% compared with pre-war, we had reduced by 8% the amount of fruit we ate.

Colonel M. STODDART-SCOTT said that the pattern we had developed in this country over many years had provided a diet suitable for our climatic conditions and industrialisation. The white-paper showed certain deficiencies in that diet as well as certain additions to it. The additions in respect of calcium and iron were extraordinarily good and he hoped would so continue. But, if we were to get the most nutritious and attracti we must have more meat, more animal fats, and animal proteins.

Dr. HADEN GUEST believed that we were now at a very high standard of nutrition. The vitality of the nation were great and food-ra price control, and subsidies were all necessary to that standard.

Mr. WALTER ELLIOT thought that a more as well as a more stimulating diet was desirable. might argue this way or that way on the adequacy diet and the lassitude or vigour of those who but vital statistics must be the final test, and many of the important curves of vital statistics h down some of the significant curves remained up. figure for tuberculosis, especially in Scotland, higher than it ought to be if the only explanat our good health was good rations and equal shares It might be that equal shares were not always fair He was sure there was much heavy work done—an in the North than in the South—for which equal do not make an equal contribution to health. desire of the ordinary person for variety in his diet be acceded to if possible. If we were to cont progress we must do our utmost to see that a varied diet was available and that where moved towards the traditional big meat ration not depend so much upon the large starch ration which we were being adequately though monotonously maintained today.

Dr. EDITH SUMMERSKILL, replying to the said the white-paper was a factual document Ministry of Food did not try to prove t the moment the national diet was at its optimum. over-all position, however, had much improved. was not satisfied with the amount of meat available but we depended on other countries for most supplies and no additional meat was available. Ministry would like to distribute more fats. A survey had revealed no signs of fat deficiency country, however, and consumption of butter, m and cooking fats was at the beginning of the about 90% of the pre-war total. It had since increased to 98%. Since last July consum flour had decreased by 19%. The decrease equivalent to 60 calories a head and the extra f sumption was equivalent to 75 calories. The spectacular result of the nutritional policy in had been the almost complete elimination of At the beginning of the century a third of the children had rickets. They either had bandy knock-knees, or pigeon chests. Now this had gone. The Government were trying to translate t which were expounded in the past into practice bring these things right into the homes of the p They looked forward to the day when they could a balanced diet with the full complement of n which everyone desired. Despite our difficult were progressing and the hard-pressed hou could look forward to the future with confidence.

Royal Assent

In the House of Lords on Dec. 16 the Royal was given to the National Health Service (Am Bill, the Nurses (Scotland) Bill, and the Adopt Children Bill.

Parliament was prorogued till Jan. 24.

QUESTION TIME

Fees at Cottage Hospitals

Brigadier R. H. RAYNER asked the Minister of H he was aware that under his regulations the future charge for private rooms Hospital would be, without and with such attendance £26 and with such attendance, 15 guineas and Hospital, without medical attendance, £10 12*s.*; and whether he would a such attendance, a reduction in these charges.—Mr. ANEURIN BEVAN These charges have been calculated in accord the requirements of the National Health Service cover the whole cost of the accommodation and provided, and I have no power to reduce them.

---

[1] See *Lancet*, Dec. 24, p. 1186.

and stool examinations are negative. The sig- opic findings described are those commonly seen of spastic or mucous colitis. The vomiting and other symptoms described—particularly the weak- distension, and discomfort—will be recognised by o have seen many cases of alimentary neurosis as very common in that condition. Improvement a course of emetine cannot be held as evidence for or against amœbiasis or neurosis since almost treatment may induce a temporary improvement in patients, and the subsequent histories in this are not discussed.

is well known that to treat patients with neurosis ugh they are suffering from an organic disease to confirm and perpetuate the neurosis,[2] and leads h needless incapacity. There can be little doubt when the diagnosis of amœbiasis is made frequently al grounds alone, large numbers of alimentary are in consequence mismanaged. The resulting invalidism and loss of working-time is almost ly greater than that incurred by a careful search stools as a prerequisite of treatment. Unfortunately actice of treating almost all alimentary disorders makes a ready appeal to some physicians tropics, who find it more lucrative and certainly exhausting to prescribe emetine than to assess lly the physical and psychological state of the t, and where necessary to persuade him or her that ic disease is present. To encourage the practice in or out of the Services is a retrograde step which long run can only harm the patient. The diagnosis sentery, carefully using all available methods, is ly satisfactory basis for treatment.

A. W. WOODRUFF

Tropical Medicine.

Lecturer in Tropical
Medicine.

—Dr. Todd's article of Dec. 17 constitutes a ge which cannot go unanswered. In my opinion ictures on Army medical policy during the Burma ign are too sweeping, possibly because his related only to a small sector of the vast Conditions in the Kabaw valley could not be d as typical of more important theatres elsewhere. therefore in order to redress the balance and to some of my own experiences during a stay in and Burma from 1942 to 1945. Arriving with the British General Hospital—probably the first to in India—I later saw the Arakan campaign through the rear, in Ranchi in 1943, and from the front, in rakan from January, 1944, onwards almost to the of the war.

the early days, regulations for the treatment of were essential, since British M.O.s had little idea to do and some Indian M.O.s even less. One surely not quibble therefore with the desirability of sing malaria before treating it, and it was no p to look at a slide of a patient not seriously ill at him an hour or two later. If it was negative, e was to repeat the film later in the day or on llowing morning. If still negative and malaria d on clinical grounds to be probable, I had no ion in treating the case as "clinical malaria." I yet to learn that this policy was frowned upon; contrary, I found that approval was given to any in charge of a medical division of a hospital if he put up a reasonable case. Certainly one should have had to wait for repeated rigors before treat- and if this happened in the Kabaw valley it was n of the main dressing-station and certainly not se who framed the regulations.

point, however, on which I agree that Army policy mistaken, was in the use of pamaquin. This was abandoned partly because of an outbreak of hæmoglobinuria which Dr. McMartin and I studied.[3] This took place during "blanket treatment" (not mentioned by Dr. Todd). Our paper described 13 cases and adduced experimental evidence that pamaquin, and not blackwater fever, was the cause. In addition "formes frustes" were discovered, while in one unit 36 out of 200 men suffered from various forms of pamaquin toxicity. Of 3000 patients studied over a two-month period at the same time, 10% suffered from symptoms which had hitherto been attributed to malarial debility.

It is true that in 1943 malarial cases were evacuated very long distances, but that was presumably the reason why my hospital, of whose medical division I was in charge, was moved down from Ranchi (Bihar) to a position in the Arakan, cheek-by-jowl with 14 Indian Divisional headquarters, well to the south of Cox's Bazaar where other hospitals were based. This was in January, 1944, and during that year 50,000 patients were admitted, of whom over half had malaria. We retained the majority of these malarial cases for the full course of treatment, which had already been started at the main dressing-station, field ambulance, or casualty-clearing station. Most—in fact the great majority—were returned direct to their units, while others were sent to the rest-camp or to one of the hospitals at Cox's Bazaar. In this way the flow of cases to the rear was stemmed, at least as far as the Arakan was concerned, although the work involved was extremely arduous.

Along with these malarial patients, we had thousands with dysentery, but amœbiasis was less often diagnosed by the medical units in front of us. "Clinical dysentery" was common and many had already been treated as cases of bacillary dysentery, often quite correctly. Our routine was to send a stool to the laboratory the morning after admission. In all cases with a negative result, both proctoscopy and sigmoidoscopy were undertaken and swabs examined on the spot. Five hundred such examinations were made, mostly by myself, and those patients who presented the typical appearances, even if the swabs were negative, were at once started on emetine. The course was continued at hospitals in our rear. There remained a residue of some 20% who had the symptoms of amœbiasis and yet in whom sigmoidoscopy and the first two stool examinations were negative. These patients were kept for a week, and as a result of further daily stool examinations many were found to be suffering from amœbiasis: the remainder were evacuated. (Within two months, 14 cases of coccidiosis, which Dr. Todd would probably have called amœbic dysentery on the symptomatology, were discovered in this hospital.) We had no reason to question the ALFSEA 1944 instructions. If these had been ignored and Dr. Todd had had his way, bacillary dysentery would have been treated with emetine, which no-one will dispute is a toxic drug. I saw what could happen to cases inadequately treated when, as medical specialist to 14 British General Hospital, I had virtually only emetine with which to treat my cases in 1942; two out of three cases relapsed.

In conclusion, I would put forward a plea that due regard should be paid: (1) to the enormous supply difficulties that the Army medical authorities had to face, which were the only reason for postponing the use of prophylactic mepacrine; and (2) to the scarcity of medical man-power, which led to the use of many medical officers of poor mental calibre. A useful purpose will have been served by Dr. Todd's provocative article if this whole matter could be placed in its proper perspective by contributions from others who served in the Indo-Burma theatre of war.

London, W.1.　S. B. DIMSON.

[2] Ryle, J. A. *Ibid*, 1939, ii, 353.

[3] Dimson, S. B., McMartin, R. B. *Quart. J. Med.* 1946, 15, 25.

each team then sends one of its members out of the room; there he is given the name of an object (a brussels sprout, a ball of wool, Buckingham Palace, Mr. C., or the like) which he must draw before his team on his return; when the team has guessed the object it sends out another representative, and so on; the first team to guess all the objects wins the bag of nuts. Finally, instead of charades, we played that silly game where the party is split into halves, and one half gives a member of the other half the name of a book or play which he must act dumbly until it has been identified by his side.

Thus to supper; and here candlelight is kinder not only to faces but to the provender (though I must say my old Dutch did a jolly good aspic jelly). After eating their fill people are apt to sit around ghoulishly staring at each other, wondering whatever brought them into such a place and company; this ebb I averted with wine, red or white (no names offered or asked). Then we rolled up the carpet, had one mandatory Paul Jones, and left everybody to do what they pleased for a change. About midnight half the party crept away—to make a long journey home, to awaken a drunken sitter-in, or merely to go to bed. The dozen who were left gathered round the fire (straight gin or whisky now) and talked till two-ish. We had *two surprises: (1) that the head*-mistress of our children's school was the life and soul of the party; and (2) that our doctor—an inveterate party man—refused to play games. "I'm the umpire," he growled when I tried to bully him; so I left him skulking in a corner. Perhaps we should have chosen simpler games.

* * *

Our secretary was good; it was one of the things on which the clinic were agreed, and we often used to say so. We even enlarged on her attributes and told the houseman she would make him an excellent wife. Whether or not we influenced him we cannot say, but he took our advice and married her.

It was during their engagement that we started to be apprehensive of our fate and wonder about her successor. Hitherto we had never been called on to spell dysdiadochokinesis or even exophthalmic ophthalmoplegia, and it did not matter if we mumbled or lit our pipes while dictating, we were always presented with our ideas of the case translated into perfect English. When she left we were not kept long in doubt, for our letters acquired a new and unaccustomed flippancy. One patient was admitted "because he vomited blood and his emotions were jet black"; another "complained of irritation from a virginal discharge"; and a third had "loss of weight in one eye." Perhaps it was comment on this last case which caused: "the sight of this man's primary growth was thought to be abominable."

Alas, our present houseman is not amenable to suggestion.

* * *

The new house-physician was the first woman resident the hospital had had. I asked her where her quarters were, and she told me next door to the matron—a little inconvenient since it was far removed from the residents' common-room, &c. But she said she was lucky to be in the hospital at all, for the superintendent was a great stickler for the proprieties and had gone into the question of her previous accommodation at other hospitals pretty thoroughly—so thoroughly that she hadn't dared say that at the last one she had shared the residents' flat with two men.

* * *

. . . As others see us. Here is what the *Boston Evening American* (Nov. 18) has to say:

> "In England, under the system of Socialized Medicine which has prevailed in the country for a year and a half, the doctors are not known officially by their name but by numbers, somewhat in the manner that inmates of a penal institution are designated. The official numbers by which they are registered and under which they function professionally are assigned to the individual doctors by Mr. Aneurin Bevan, the Minister of Health. Some 18,000 of the country's 20,000 doctors are thus designated, theoretically by their voluntary consent but in many cases under pressure and intimidation inseparable from any form of the totalitarian system."

Letters to the Editor

ARMY MEDICINE IN THE LATE WAR

SIR,—In his article of Dec. 17, Dr. Todd app confuse the curative action of mepacrine with its p lactic value. Though prophylactic mepacrine was on a small scale in Southern Europe and in North I before 1939, its value and the necessary dosage only established by the work carried out at Cairns in the war. Supplies of mepacrine ('Atebrin') came Germany, and some time elapsed before adequate sup could be manufactured in England.

Clinical diagnosis must have been easy for him his cases showed fever every second or third day, why he should have waited this time to make a dia I do not understand. A blood-slide would have inva given him a diagnosis within thirty minutes of se the case if his staining technique was correct. In experience treatment was never delayed for a labora diagnosis. I know of no disease in which a labora diagnosis can be made more easily or quickly t malaria. The trouble in the Army was due to the of adequate provision for laboratory diagnosis; I agree that in a forward area there is no occasio insist on laboratory diagnosis.

Dr. Todd attributes deaths from malaria to delay treatment. I know of many deaths where imme treatment was given, and I know of no treat which will prevent a certain mortality with malign tertian (M.T.) infections—that is, excluding personne adequate suppressive mepacrine.

His account of the ease with which civilians d with malaria is ludicrous. I have known of deaths f M.T. infections among European civilians, and of bl water fever associated with quinine prophylaxis.

•

SIR,—Dr. Todd (Dec. 17) brings forward many vi which will be recognised as sound by physicians have served in the Forces in India and Burma. Som his views concerning the treatment of amœbiasis, h ever, are open to criticism. He rightly quotes amœbiasis was "the most important single caus protracted illness and invaliding" from the Bu theatre.[1] He does not mention that neurosis was an important cause of invaliding and that alimen neuroses are frequently confused with amœbic dysent

To treat patients such as he describes as cases of am dysentery before examining their stools undoubt causes large numbers of alimentary neurotics to treated for dysentery. This in turn leads them to belief that their symptoms are of organic origin an all the subsequent trouble arising from that belief. the series of which he made a special study, repe stool examinations failed to reveal vegetative form cysts of *Entamœba histolytica*.

> "Their histories were strikingly similar. . . . All plained of anorexia and abdominal discomfort, pain distension, particularly after eating. Ten (42%) stated they had had much vomiting. All had had a certain am of diarrhœa, often in spells alternating with constipa though this was not the main complaint. Thirteen (5 stated that they had sometimes passed blood in the st All complained of weakness and some loss of weight."

If, as Dr. Todd recommends, such cases are to be nosed on clinical grounds, these symptoms surely w suggest an alimentary neurosis rather than am dysentery. Vomiting does not occur in amœbic b infections of such mildness that sigmoidoscopy show

PEPTIC ULCER

SIR,—Dr. Martin and Dr. Lewis are to be congratulated on their very useful survey (Dec. 17) of peptic-ulcer cases followed up after ten years. Their achievement of such a low lapse-rate as 8·2% requires us to view their data and conclusions with considerable respect. At the same time their sample of cases is not at all representative of the ulcer population in general. In any given area, and in such a short space of time as four years, only a fraction of the ulcer population would be admitted to hospital for treatment. That fraction depends chiefly on the hospital facilities in the area and the age-distribution of the population, but is probably rarely more than 20%. If 20% were selected at random from the ulcer population, all would be well with your contributors' conclusions; but, as they themselves state, it is the severe and the complicated ulcer cases which are most frequently admitted to hospital. Consequently the authors' statistics, though most valuable in themselves, refer only to this selected sample containing a large proportion of severe, intractable, and complicated cases, of which we do not even know the age-distribution.

Regarded in this light, their figures for the incidence of hæmorrhage, perforation, and death among patients medically treated are seen to be unduly gloomy, whereas their conclusion that the longer the ulcer history the less likely is the ulcer to heal under medical treatment, though weakened by their lack of scrutiny of the milder cases, is probably sound.

There is one other matter which might cause confusion. The article speaks of regimen and treatment in the same sense. This, I think, is wrong. The essential feature of medical treatment of peptic ulceration is rest in bed; the essential feature of an "ulcer regimen" is the achievement of a way of life which minimises ulcer distress. Such a regimen is usually initiated by medical advice but developed by the patient out of his own experience; it rarely bears a close relation to the schedules drawn up by doctors. Surely, then, the only conclusion with regard to the effectiveness of medical treatment which can be drawn from the figures is that within the select sample studied a variety of "ulcer regimens" had no affect on the natural course of the disease. The question whether early and effective medical treatment can effect the prognosis remains unanswered, since the authors have not analysed their data in this respect. For example, their finding that short-history cases do better than long-history cases may mean that hospital admission and treatment by rest, early in the course of the disease, has a beneficial effect in the long run.

It is hoped that the advice of Dr. Martin and Dr. Lewis will not lead to an orgy of gastrectomies in patients with fairly mild and infrequent symptoms. Such cases do exist and have not really been taken into account by them in compiling their rather gruesome and depressing figures. The general rule that no patient should be allowed to suffer gastrectomy until he has already suffered considerably from peptic ulceration should still be observed. If it is not, surgeons can expect an increase in the number of patients who, after gastrectomy, complain that their last state is worse than their first.

Department of Medicine,
University of Bristol.

J. NAISH.

SIR,—It is always refreshing to find medical men, whether physicians or surgeons, publishing the bad results of their own methods of treatment. A careful ten-year follow-up of a series of peptic-ulcer patients, such as that reported by Dr. Martin and Dr. Lewis, was long overdue. Their conclusion—that medical treatment did not appear to have influenced the natural course of the disease—is all the more likely to be accepted because they *cannot* be accused of having any surgical bias.

Their figures show that chronicity in an ulcer be regarded as established until ten years from the of its onset. It is, however, difficult to accept argument that for this reason gastrectomy sho urged only when an ulcer has been present for ten They say that "it is as important not to advise g tomy for an ulcer which may still heal as it is to gastrectomy when chronicity is established." surely this is a fallacious argument. Their results that during the ten years that these patients are w for their gastrectomies 8% will die from hæmorrh perforation (tables XIII and XVI), and that of th survive the ten years 78% will still have active (table X).

The modern operation of high partial gast (removing the pyloric antrum and at least three-qu of the body of the stomach) carries a mortality-ra well under 5% in the best hands (0·5% in one series), and is followed by recurrent ulceration more than 3% of cases (nil in some series). If (as and Lewis state) the mortality-rate for the coun a whole is nearer 15%, doctors should entrust patients to those surgeons whose results are rather than deny their patients the benefits of su A proportion of patients develop post-gastrec symptoms, but in very few are these as incapaci as the symptoms of active ulceration. Of patients have undergone gastrectomy, 95% are well sa with the result, are free from pain, and are abl follow a normal occupation without dietetic restrict It is true that we have few records of ten-year follo in these patients, but the tendency up to 3½–4 y is for their condition steadily to improve.

Surely sufferers from peptic ulcer—especially t who cannot follow an ulcer régime by reason of occupation, economic status, or temperament—sh be offered the advantages of a gastrectomy as soo it is clear that their lives are being seriously distu Even in the best hands the mortality-rate for gastrec increases with the length of history, especially this exceeds five years, and with age; so by ke the patient waiting the hazards of operation are incre Many who had symptoms for much less than ten are coming to the post-gastrectomy follow-up c saying that they wish they had undergone an oper much earlier. Martin and Lewis's results confirm they would have been very well advised to do so.

Department of Surgery,
University of Liverpool.

RICHARD B. WELBOU

VASCULAR DISEASE

SIR,—The mortality from arteriosclerotic diseas been shown to change materially during the war Norway, Dedichen and Strøm[1] found a marked red in the death-rate from arteriosclerotic and c vascular diseases, starting in 1939 and stopping in Malmros[2] has recently shown a similar change i mortality from coronary thrombosis in the Scandin countries during the war; and he attributes the de to rationing, especially of fat.

Since arteriosclerosis is presumed to be a c disease, this fall in the death-rate was difficult to ex Therefore, stimulated by the theory of Winterni were anxious to know whether the same fluctuation be shown in the incidence of thrombo-embolic pheno This investigation, carried out in surgical departm of Ullevål (chief, Carl Semb) by Adelsteen-Jensen, the same fluctuation during the war as in the mo from cardiovascular diseases.

Before the results of this last investigation were to us we had started experiments with the inten

Obituary

GORDON GORDON-WATSON

C.M.G., F.R.C.S., F.A.C.S.

ordon-Watson, consulting surgeon to 's Hospital, died in York on Dec. 19

Rev. H. G. Watson, vicar of St. Leonards hire. Charles Gordon-Watson himself Catholic while still a young man. He St. Mark's, Windsor, and St. Bartholo- ınd after taking the Conjoint qualifica- ıeld house-appointments at Barts and ıd Norwich Hospital. In 1899 he went :o serve as a civil surgeon in the war. ıe returned to England and in 1902 he and quickly won recognition. Besides his own hospital he also joined the staffs of the Metropolitan Hospital, St. Mark's Hospital, and St. Andrew's Hospital, Dollis Hill. He was also surgeon to the Jockey Club and the National Hunt Committee.

On his return from South Africa he had joined the 3rd Middlesex R.G.A. Volunteers and when the Territorial Army was formed in 1908 he received the rank of captain. Soon after the outbreak of war in 1914 he took charge of the Duchess of Westminster's Hospital at Le Touquet. Later, with the rank of colonel, he became consulting surgeon to the France and in Italy. For these services C.M.G. in 1915 and K.B.E. in 1919.

Charles became interested in the treat- ma of the rectum with radium, and 1 1931 he wrote a number of authorita- ıis subject. But after several years of igation, with a careful follow-up of his ed it as a regular method of treatment. his work was linked his interest in the ancer Campaign, where for many years of council and chairman of the investi-

He was also vice-chairman of the tee of Mount Vernon Hospital. Though r his versatility in general surgery—for orated with Marsh in a book on *Diseases* e wrote the article on diseases of the 's *System of Surgery*—he will be best ıaps for what he did to advance rectal 1937 he chose as the subject of his at the Royal College of Surgeons the of Cancer of the Rectum. W. B. G., C. N. M. and the staff of St. Mark's Hospital write: "In his work here certain things stand out in our memory: his kindness and thoughtfulness to patients were proverbial, but on occasion the atmosphere in the operating-theatre could become distinctly explosive! He delighted in demonstrating to foreign visitors and made them feel at home when he shouted forth a few words in their native tongue. He was a staunch, and perhaps the last, adherent of the clamp and cautery method for piles, always referring to his cautery as the 'fiery furnace.' Another feat was his extended Whitehead's operation for removal of large villous tumours of the rectum, and he would delight in removing outrageously long specimens of bowel by the perineal route. In 1935, in collaboration with Harold Dodd, he published his well-known paper on infection of the intramuscular glands, and this was, we believe, his last surgical contribution. We shall remember Sir Charles for his breezy and friendly personality; we admire him for his courage in adversity, and feel that we have lost a popular colleague, a sportsman, and a great and lovable character in British surgery."

A member of the council of the Royal College of Surgeons from 1924 to 1940, he also served a term of office as vice-president, and he was for many years treasurer of the Medical Protection Society. With Mr. Lockhart-Mummery he founded the Proctological Society which later became the proctology section of the Royal Society of Medicine. In 1931 he was elected an honorary fellow of the American College of Surgeons.

As lecturer in surgery Gordon-Watson was a popular teacher at Barts, and it was typical of his thoughtfulness for his students that his was one of the first theatres which had a viewing mirror for those who came to watch his operations. He freely admitted himself to be an "incorrigible Tory," and he was a staunch believer in the value and standard of English clinical teaching which he himself did so much to uphold. Students, he asserted, became "self-reliant because partly self-taught under capable guidance."

During the late war, from 1939 to 1942, with the rank of temporary major-general, he once more served as consulting surgeon, this time to the Army at Home. His last years were spent in York.

J. P. L.-M. adds: "Gordon was an outstanding personality. He was one of those men one could always rely on in a difficult situation to do the right thing regardless of his own personal interests. A keen sportsman, he was a good golfer and an excellent shot, and when he took up fishing he soon became quite a good salmon and trout fisherman. He and I often went for sporting holidays to Norway and Scotland. He was also a good bridge player, having been schooled in the old whist days. Whatever Gordon did he always did with all his energy and he always did it well. He was a charming friend and one of the most honest men in his opinions and deeds that I ever came across."

Lady Gordon-Watson died in 1935. Lieut.-Colonel D. M. L. Gordon-Watson, M.C., their only child, commands the 1st battalion, Irish Guards.

SELWYN GURNEY CHAMPION

M.D. EDIN., L.M. DUBL.

Dr. Champion, a world-famous student of proverbial folklore, died at his home in Framfield on Dec. 13. He was born at Burgess Hill in 1874, qualified in Edinburgh in 1897, and proceeded to the M.D. in 1902, his thesis being highly commended. A keen athlete, he played rugger for the university, and rowed in the university crew. After 32 years' general practice in Bournemouth he retired to Burgess Hill, and later moved to a delightful house in Framfield.

When still a boy, Champion became attracted to proverbs and remembered all his life that it was the saying "A rolling stone gathers no moss" that first intrigued him. He became a great collector and master of proverbs and devoted his years of leisure, up to the last day, to this fascinating study. His two outstanding works are *The Eleven Religions and their Proverbial Lore* (1942) and *Racial Proverbs* (1938). In this last monumental work, the only one of its kind, 26,000 proverbs have been gathered from every part of the world, and grouped together according to their country of origin. This collection proves, as Champion says in his intro-corresponding figures for the heart-rate were 134 and 96 per min.; this accounts for an increase in the heart-beat volume from 18 to 28 ml.—i.e., about 55·5%—which is indeed a considerable hæmodynamic effect.

With these objections, what weight can be attached to the assertion that "neither in the patients with sinus rhythm nor in those with auricular fibrillation is there any correlation between the relief of congestion and the slowing in heart-rate"; or to the sentence stating that "it is significant that atropine-induced acceleration did not lower cardiac output or increase congestion"?

London, W.1. J. PLESCH.

THE LIBRARIAN IN THE CHILDREN'S WARD

SIR,—At a conference held by the Guild of Hospital Librarians on Nov. 9, the audience was surprised to learn that at several hospitals, including large and well-known establishments, librarians were not allowed into the children's wards at all. The opposition, so far as we could gather, comes mainly from the nursing staff, and the reason given is usually "infection." It is not clear whether the librarian or her books are held to be the conveyors of disease, but in any case we respectfully take leave to doubt whether the objection is a reasonable one. If it were valid, it would surely be applicable to all children's wards, which is not found to be the case. Where the librarian is welcomed, difficulties about infection traceable to her presence or to the distribution of books do not arise in practice.

It also emerged at the conference that where the teacher acts as children's librarian, the books are sometimes locked up at the beginning of the school holidays and the children are deprived of this solace just when they need it most. A few old books left for the nurses to distribute do not in the least meet their wants.

Do these defects in the hospital library service really matter? The attention now being paid to the psychological effect of hospital admission on children has shown how bored and frightened and homesick they can be behind a mask of docility. It seems strange that the best and cheapest means of comfort, occupation, and mental stimulation—i.e., a good supply of suitable books—is still not being fully utilised.

TREATMENT OF WOUNDED IN MALAYA

SIR,—I gather from my colleagues who served in the 1914–18 war that much of the surgical experience that was dearly bought in that war had to be gained all over again in the early years of the 1939–45 war. Those of us who served in the late war hoped that the lessons learned would not be quickly forgotten. The Royal Society of Medicine, in convening the Inter-Allied conferences on war medicine and in publishing these proceedings in book form, has done everything possible to ensure that the knowledge gained should not be lost.

It is therefore all the more regrettable to learn from a statement by the Secretary of State for War[1] on the number of surgeons in Malaya that after less than five years so much has apparently been forgotten. The campaign in the Western Desert established the value of grouping the field surgical unit and field transfusion unit at the main dressing stations of a field ambulance, with instructions to deal with "life and limb" surgery. As a result of siting these units well forward, where they could deal with such cases as penetrating wounds of the abdomen and thorax and severe compound fractures of the femur, countless
saved which would certainly have been lost
patients had had to make the journey back to a c
clearing station or general hospital. I appre
the problems of the jungle are not those of the
Desert; but those of us who went from the
Sicily and Italy, and later to Normandy, found
principles of forward surgical organisation did
very greatly in the various theatres of war.

It would appear from the War Minister's
that there are only four Army surgeons in
Singapore island; and this number would
inadequate to carry out early surgical trea

duction, that proverbial wisdom is exactly the same all the world over, differing only in the rendering.

Men are known by their companions, and Dr. Champion's communion with the quintessence of human philosophy became him happily. He was a delightful friend, and truly lovable. H. P. S.

ALAN JAMES HIRD

M.B., B.SC. GLASG., M.R.C.P.

SCHOLASTIC distinction, professional skill, and charm of personality were all finely blended in the life of Alan Hird. At the early age of 16 he was dux of Glasgow Academy, and he was equally outstanding as an athlete. His wide range of interest in sport embraced rock-climbing, and it was on the treacherous slopes of Am Bodach in Inverness-shire that he missed his footing in a moonlight climb and fell to his death.

[Annan

He graduated at Glasgow University in science in 1937, proceeding to the degrees of M.B., CH.B., with honours, in 1940. It was clear that he was one of the most able graduates produced by the medical faculty of Glasgow in recent years. He was a voracious but critical reader, and his general conversation no less than his contributions to formal discussions created a lasting impression of mental poise and strength of character. At the same time he was popular among his contemporaries and seniors, for notwithstanding his notable gifts he was modest almost to a fault. Students recognised in him a physical and intellectual robustness which dispelled shyness and marked him out as a teacher of great promise; and indeed this had already been recognised by his appointment as lecturer in medicine in Professor NcNee's department.

Serving in the R.N.V.R. during the war, he sought no furtherance of his personal interests, but was more than content to be medical officer in a destroyer. Here his personal qualities and his professional competence quickly ensured his acceptance by all ranks. Soon after returning from active service he took his M.R.C.P., and threw himself wholeheartedly into clinical work in the hospitals and hæmatological research. His publications, though few, revealed an insistence on accuracy and conciseness.

Hird's untimely death will be felt immediately as a serious loss to the Glasgow school; and with the passing of the years there will often be occasion to lament that this brilliant young physician did not survive to take his place in Scottish medicine. Regret may be intensified by wondering whether the choice of a less perilous sport might not have spared him. But a vigorous and challenging attitude to life was as much a part of Hird's philosophy as were his devotedness to his patients and his loyalty to his friends.
